The Port of Shanghai.—The native city of Shanghai, on the left or west bank of the Whangpoo branch of the Yangtze, is the nucleus of the vast urban agglomeration which now bears its name. Although a city of some antiquity and an outlet of the rich deltaic region, it had little more than local importance prior to the Treaty Port period. Its commerce was considerably less than that of Ningpo, on a deep-water harbour on the southern shore of Hangchow Bay, with a position relative to the Yangtze delta comparable to that of Marseilles in relation to the Rhône. In the course of the naval operations during the first Anglo-Chinese or "Opium" war the British realized the possibilities of Shanghai and at the Treaty of Nanking (1842) it was included among the five "Treaty" ports opened to foreign trade. In the following year the English settlement was located to the north of the native city and was defined by the Soochow Creek on the north, the Yang-king canal on the south and the Whangpoo river on the east. Later the narrow strip between the Yang-king canal (now filled in) and the native city became the site of the French settlement, while the American settlement grew up on the northern side of the Soochow creek. The local advantages of the site were a position on the estuary as near to the sea as physical circumstances permitted a deep water port to be formed and the junction with the Whangpoo of the Soochow Creek, which linked it with one of the richest regions of the delta. To set against these advantages are certain drawbacks with which modern Shanghai is still contending. The first is the fact that the city is wholly built on the alluvial deposits of mud and silt with which the Yangtze has been gradually filling up the original basin that now constitutes its delta. The International Settlement stands on what was formerly a marshy swamp and, although by careful drainage it has been converted into a fairly healthy site, the soft character of the ground limits the height and weight of the buildings placed upon it. Thus, with the rapid growth of population, the city tends both to be congested with small buildings and to expand over a very large area. Hence a difficult problem of regional planning has emerged. The second difficulty concerns the character of the Whangpoo, on which Shanghai depends for its communications with the south channel of the Yangtze and the open ocean. As ships began to increase rapidly in draught the many shoals in the river and the shallowness of the water at its bar threatened to make Shanghai inaccessible to large vessels. The problem has now to some extent been solved by the work of the Whangpoo Conservancy Board which derives its authority directly from the Chinese Government and comprises the following officials: the Commissioner for Foreign Affairs for the Province of Kiangsu, the Shanghai Commissioner of Customs and the Shanghai Harbour Master. By means of a series of costly works, extending over a period of more than 20 years, the Whangpoo has been converted from an irregular creek, progressively silting up, into a good shipway with a minimum depth of 24 to 26 feet at the lowest tides and a high water depth of 30 to 42 feet available throughout the year. Continuous dredging is necessary to maintain these depths, which are not yet sufficient and the largest liners do not enter the river but discharge passengers and cargo into tenders and lighters outside Woosung, where the Whangpoo enters the Yangtze, and which has become the recognized outport of Shanghai. At the present time, however, it is not so much the navigation of the Whangpoo as the entrance to the Yangtze itself some 30 miles below Woosung, which presents the most serious engineering problem. The increase in the draught of ships has been so great in recent years as to make the navigation of the Yangtze bars difficult, and while this affects the Yangtze ports in general, it particularly concerns Shanghai as a world port. The present position is that whereas many ships having draughts of about 30 feet now arrive off the river and a further increase of draught is inevitable, the depth in the main channel of the Yangtze at the "Fairy Flats" is only about 16 to 17 feet at extraordinary low water, 26 to 28 feet at neap high water and 30 to 32 feet at ordinary spring high water. The deepening of one of the bars seems indispensable to the future welfare of the port of Shanghai but, owing to the great size of the bars, which are many miles in length, to the rapid changes produced by tidal forces and the absence of solid foundations for training works, the task involved is of immense magnitude. The problem has been engaging the attention of the Whangpoo Conservancy Board for many years and in 1921 it convened a committee of harbour and river experts whose detailed report, made after a thorough investigation, is now being considered. The gist of the recommendations is that by means of the largest dredgers procurable a channel should be cut through the Fairy Flats, deepening it "gradually foot by foot to as great a width as required and as possible and to provide as soon as feasible a channel of 600 feet bottom width for the passage of ships drawing 33 feet at ordinary neap high water." The committee further recommends the expansion of the existing Whangpoo Conservancy Board "into a new body, which might be known as the Shanghai Harbour Board, with more extended powers and more directly representing shipping and trade interests." It is pointed out that "the inauguration of a strong harbour policy at the earliest possible moment is a *sine qua non* for the prosperity of the port, will strengthen the position of Shanghai as the principal transhipment and distributing centre, and will confer immense benefits upon the shipping and commerce of China."

Apart from its maritime and river communications Shanghai is an important railway centre.

(1). It is connected by the Shanghai-Nanking (Hu-Ning) railway with Nanking (194 miles) at the apex of the delta, whence by ferry across the river it is linked by the Tientsin-Pukow railway with Peking, north China, the South Manchurian and Trans-Siberian railways. By the overland route Shanghai can be reached from Western Europe in about a fortnight. There is a local branch of the Shanghai-Nanking railway to the outport, Woosung.

(2). The Shanghai-Hangchow-Ningpo railway (Hu-Hang-Jung), with a mileage of 178, connects the metropolis with the southern margins of the delta, the important districts round Hangchow Bay and the ancient emporium of Ningpo, with which it has very intimate commercial relations.

Trade.—The chief function of Shanghai is to serve as the principal entrepôt for the trade of central and much of north China and particularly to transact trans-oceanic business. The total tonnage using the port in 1926 was returned at 33,937,466, making it—on the criterion of tonnage—the premier port of the Far East and the fifth port of the world. Of this tonnage the share of the British Empire was 32·67%, of Japan 27·96%, of China 15·05% and of the United States of America 12·05%. Approximately half the total shipping is engaged on coastal and river trade, shared as follows: British Empire 37·98%, China 30·56%, Japan 21·19%, U.S.A. 1·75%.

Of the total *ocean* shipping of Shanghai, Japan in 1926 claimed (in tonnage) 34·48%, the British Empire 27·56%, and the United States 21·94%. About one-half of the shipping engaged on the trans-Pacific (northern) trade, which forms approximately 10% of the total, is owned by the United States and most of the remainder is shared between the British Empire and Japan.

The general character of Shanghai's trade is indicated by the following analysis:

	1924 Millions of Haikwan Taels. (H.T.=3s.7$\frac{15}{16}$d. in 1924)
Imports	
Foreign goods from foreign ports and Hongkong	483·5
Foreign goods from Chinese ports	4·6
Chinese goods from Chinese ports	311·0
Total Imports	799·1

Exports

Foreign goods re-exported to foreign ports	12.7
Foreign goods re-exported to Chinese ports	174.2
Imported Chinese goods re-exported to foreign ports	155.9
Imported Chinese goods re-exported to Chinese ports	63.9
Local Chinese produce exported to foreign ports	120.5
Local Chinese produce exported to Chinese ports	263.9
Total Exports	791.1

The table indicates the importance of the re-export business which forms about 40% of Shanghai's gross trade.

In 1926 Shanghai yielded no less than 41·81% of the total revenue of the Maritime Customs, a fair indication of her share of China's foreign trade. Swelling the total volume of trade there is, moreover, a large importation of Chinese products in junks which passes through the "native" customs. The possibilities of the future are indicated by the fact that, so far as purchasing power is concerned, China is still in its infancy and the Yangtze valley with its 180 millions imports less than Australia with six millions. The list of foreign goods imported into Shanghai is increasingly varied but considerably the most valuable items are cotton piece goods (grey, white or dyed, printed, etc.) and raw cotton (including thread and yarn) which in 1926 represented respectively about 87 and 89 million Haikwan Taels out of total imports valued at 596 millions. In 1926 Shanghai took over 80% of the total Chinese import of foreign cotton. Among other outstanding imports are tobacco, sugar, oils and soap, cereals and coal. Out of a total export trade in 1926 valued at about 362 million H.T. silk, silk materials and products accounted for nearly 154 millions, vegetable products (particularly bean and wood oil) 78 millions and textiles and textile products other than silk nearly 37 millions. An important and growing item is the export to Europe of frozen eggs, albumen and yolk. The chief participants in the import trade of Shanghai are the British Empire, supplying cotton piece goods, woollens, raw cotton (Indian) and machinery, the United States (machinery, tobacco, wheat and kerosene), Japan (cotton piece-goods and coal) and China itself (raw cotton, coal, metals, hides and skins). The United States is the chief foreign market for Shanghai, which is responsible for 33% of the total Chinese exports to America. No less than 65% of Shanghai's exports to U.S.A. consists of raw silk and silk products.

Industrial Life.—Shanghai is not only China's premier seaport and commercial metropolis, it is also incomparably the chief manufacturing centre of the country and the city where the new industrial activities and tendencies are most conspicuously displayed. This is the result of many causes, chiefly connected with its geographical position as the gateway of commercial China and the base of Western influences. Raw material reaches it from all parts of China and from many foreign sources. It lies in one of the most densely peopled regions of the country, with traditional skill in handicrafts. Fuel for power, although comparatively lacking in the immediate vicinity, is cheaply imported The main reliance is on coal imported chiefly from Japan, the Kaiping field of Hopeh (Chihli) via Chinwangtao, Fushun near Mukden in Manchuria and from the Shantung fields via Tsingtao, while further supplies from the interior coal basins of Shansi, Honan and Hunan reach it by the Yangtze from Hankow. Finally the immense opportunities for industrial development, the immunities hitherto enjoyed by the International Settlement and the relative security which it has offered, in contrast to the troubled conditions of the interior, have attracted not only foreign but Chinese capital. The rapid expansion of native industries in the Shanghai area is one of the most noteworthy features of recent years, especially during and since the World War (1914–18). This is strikingly shown by the increased importance of "Total Exports of local origin" in the returns of the Maritime Customs. In the decade preceding the War they ranged in value from about 70 to 95 millions of Haikwan Taels per annum. Since 1918 they have never been less than 200 and in 1924 reached 384 millions. Their value is now about half that of the net trade of the port. The major industries of Shanghai are concerned either with her primary activity as a sea-port, *e.g.*, shipbuilding, for which there are now five yards, or with the large-scale manufacture of raw materials on modern factory lines. Of the latter the most outstanding is the cotton industry whose development has been remarkably rapid. There are at present 58 cotton mills in Shanghai out of a total of 119 in China. They employ over half the total number of cotton operatives in the whole country and account for 60 per cent of the looms and 52 per cent of the spindles used in China. At first it was mainly a Western and Japanese industry but since the War there has been a steady advance in the Chinese ownership of mills. The present position is as follows:—

	Labourers
30 Japanese cotton mills employing	58,113
24 Chinese cotton mills employing	49,908
4 British cotton mills employing	16,500
Total, 58	124,521

The four British mills are the only cotton factories of this nationality in China but 70% of the spindles used in Shanghai are of British origin.

Other large industries of the same type include steam (silk) filatures—economically a very promising development for China—over 40 modern rice-hulling factories, leather factories and paper mills. Shanghai is one of the greatest centres of the engineering industry in the Far East. Among the largest enterprises of this kind are the Kiangnan Dock and Engineering works (Chinese Government) (dock), the Shanghai Dock and Engineering Co., Ltd. (British) (5 docks), New Engineering and Shipbuilding Co., Ltd. (British), the Marine Motor Works (British), China Engineering Works (Chinese), Eastern Engineering and Shipbuilding Works (Sino-Japanese). There is also a great variety of miscellaneous industries, including cigarette factories, egg product plants, meat and fruit-canning establishments. Apart from factories fully equipped in western fashion there is a large number of small workshop handicraft industries of traditional type and intermediate establishments combining the old and the new features.

Social Problems.—The rapid development of industrialism in Shanghai has created a city proletariat of a type new to China and much larger than in any other Chinese centre. A recent estimate places the number of industrial workers, disregarding wharf, ricksha and other transport coolies, at nearly 300,000. These include 66,000 cotton mill operatives, 15,300 iron workers and 14,000 workers in tobacco factories. They are drawn from a wide area and many of them are men who have left their families in distant villages and speak a dialect different from that of Shanghai, which belongs to the Wu group. There is also a large element of female labour which is particularly employed in the steam filatures and hosiery mills. Although the conditions under which factory labour is carried on differ greatly from the traditional methods of native production, the Chinese artisans in Shanghai have earned the reputation of being good industrial workers, and, relative to the wages received, the standard of efficiency is high. Labour is abundant and the struggle for existence is tense. Until recently there were no regulations governing employment in factories. Under such circumstances the evils associated with the early days of the Industrial Revolution in England were certain to appear in an aggravated form. In the years succeeding the War the social conditions of the Shanghai millworkers attracted widespread attention. In response to considerable agitation and following the example of Hongkong, a commission of enquiry into child labour was appointed by the Shanghai Municipal Council. The report of the commission in July 1924 disclosed deplorable conditions, and the Municipal Council initiated regulations relating to child labour, designed within a period of four years to eliminate the employment in factories of all children under twelve years of age. At the same time improvements with regard to the safeguarding of machinery and the general protection of workers began to be introduced. The problems, however, still remain acute. It has been quite definitely shown (*see* the impartial discussion in Dame Adelaide Anderson's "Humanity and Labour in China") that as a whole the Western millowners have a good record and that the conditions in the British cotton mills are above the average. The problems, indeed, are inherent in the introduction of the Western industrial system into a country with an abundant labour supply, a low standard of comfort and an entirely different tradition of craftsmanship. In Shanghai the situation is much

aggravated by the special housing difficulty arising out of the conditions already mentioned. The International Settlement and its immediate suburbs are already densely occupied with houses; land is dear and rents are high. Many of the unskilled workers, especially the men without families from distant parts, are therefore living under unhealthy conditions in wattle huts on the outskirts of the city beyond the boundaries of the Settlement, and are completely cut off from the traditional sanctions of Chinese family life. Meanwhile labour under external influence has begun to organize itself and all the phenomena of industrial unrest have been conspicuously displayed. In 1913 the National Labour Party was formed in Shanghai and the Federation of Labourers and Farmers in 1916. The first important strike of a modern type was that of the seamen in January 1922, which particularly affected Hongkong, and this was followed by many others and a great extension of the union movement. The strongest unions are those of the seamen, mechanics and textile workers but their funds are at present small and the membership uncertain. While the majority of the strikes seem to have been chiefly inspired by economic grievances, *e.g.*, low wages or alleged ill-treatment, the industrial issues during recent years have been increasingly complicated by political questions affecting the status of foreign powers in China, particularly since the "Shanghai incident" of May 30, 1925. On this occasion a demonstration organized by labour unions and students to protest against the killing of a workman by a Japanese foreman culminated in the firing by the police of the International Settlement on a crowd advancing on one of the police stations. Many subsequent strikes were of a purely political character. In the most recent phase the organisation of the workers and the Union Movement have been largely directed by the Kuomintang or Nationalist Party. Many conflicting tendencies are visible but there is a strong movement to prevent the development of class warfare and it is the hope of some that the ancient Chinese guild system can be adapted to meet the requirements of the new industrial situation. Much may depend on the degree of co-operation between the authorities of the International and French Settlements and those of the large areas outside under Chinese jurisdiction which are now known as Greater Shanghai.

Population and Administration.—The Shanghai urban agglomeration now consists of six main areas: (a) The Old City, dating from the eleventh century A.D. (b) The International Settlement. (c) The French Concession. (d) A northern outer suburb: Chapei. (e) An eastern suburb: Pootung. (f) A southern suburb: Nantou.

The city in the wider sense covers an immense area. The International Settlement, made up of the original British and American concessions and with boundaries extended in 1893, comprises 5,584 acres and has a population of 30,565 foreigners and 802,700 Chinese. The adjacent French concession, about 2,525 acres in extent, contains 7,811 foreigners and 289,261 Chinese. The settlements, and particularly the original British concession, form the central districts, comprising the principal commercial quarter and the famous river front or Bund. Their hinterlands and especially that of the French concession, are mainly residential in character, laid out in long avenues. But the "eastern" district of the International Settlement, following the southward bend of the Whangpoo below the Bund, and also both shores of the Soochow Creek for a distance of about seven miles, both within and beyond the Settlement's limits, are completely industrialised and thickly studded with factories and warehouses. Of the same character are Pootung on the southern side of the Whangpoo and the suburb of Nantou, which is a westward outgrowth along the river banks of the old native city of Shánghai. The built-up portions of Greater Shanghai outside the International Settlement and the French Concession are estimated to cover about 2,800 acres. The total population of the Shanghai urban aggregation is well over one and a half millions and is rapidly increasing. The resident foreign population (on basis of five years' residence) has been recently estimated as follows: Japanese, 14,230; British, 7,047 (including 1,177 British Indian subjects); Russians, 2,972; Americans, 1,800; Portuguese, 1,402; other nationalities, 3,034. The Chinese population is drawn from many areas, but a very important element is represented by the large influx of men from Hangchow and Ningpo, who maintain close relations with their own home towns and are said to number 400,000. There are also some 160,000 labourers from Canton and Swatow.

Apart from native industrial establishments, Shanghai is the headquarters of many important Chinese organisations, such as the Y.M.C.A., and the centre of many modern movements of a cultural, religious and educational character. It contains a large number of colleges and higher-grade institutions, some maintained by missionary organisations (many of which have their headquarters in Shanghai) and some by the provincial (Kiangsu) or national government, as well as many private enterprises. There is in this great city, where perhaps more than in any other oriental centre East meets West, abundant opportunity for cultural interchange, and in the sphere of religious and similar movements this has already been productive of good results. In the main, however, the Western commercial communities in Shanghai have so far come little into contact with the Chinese apart from business relations, chiefly transacted through compradores.

The administration of Shanghai reflects the special circumstances of its origin and growth and has no exact parallel elsewhere. Although it forms a single urban unit, there are three distinct administrative areas: the International Settlement, the French Concession, and the Chinese Greater Shanghai. The International Settlement, as such, dates from 1854 when the British, French and American consuls drew up a code of regulations applicable to the two concession areas which then existed, those of Great Britain and France. The concession subsequently obtained by the United States was included within the same jurisdiction in 1863, but meanwhile (1862) France had withdrawn from the joint arrangement, and ever since the French Concession has constituted a distinct municipality. Other Treaty Powers, particularly Japan, have since entered the field and have adhered to the regulations governing the International Settlement. It exercises complete powers of self-government, including police control, and the efficiency of its administrative arrangements soon earned it the title of "The Model Settlement." The executive power is a Municipal Council, elected until recently entirely by the foreign ratepayers. The Settlements were originally intended only for foreign merchants, but at a very early period Chinese refugees and others were allowed to reside within their boundaries; and especially since the period of the Taiping Rebellion, which created great insecurity in the lower Yangtze region, they have constituted the immense majority of the population. As participants in the benefits of the Settlement administration they were required to pay municipal taxes, but until 1926 they had no voice in the conduct of its affairs. In that year, in deference to the rising demands of Chinese nationalism, the Municipal Council sanctioned the appointment of three Chinese members to the Council, which now consists of five British members, two American, two Japanese and three Chinese. Another important recent development is the Chinese scheme to unify the administration of the urban district outside the Settlements, including Chapei, Nantou, Pootung and Woosung, and a large area at present agricultural in character, into a new municipality or "Directorate of the Port of Shanghai and Woosung." The conception of a Greater Shanghai involves the co-operation of the Settlement and Chinese authorities in a regional planning scheme and the adjustment of many difficult issues, such as the status and control of extra-concessional roads. The problems involved in the promised relinquishment of extraterritorial rights in China by the western Powers must also be particularly acute in the case of Shanghai.

SHANGHAI, to drug and ship aboard a vessel needing hands.

SHANHAIKWAN ("The Gate between mountain and sea"), an important Chinese garrison town (population about 30,000) in the extreme north-east corner of the province of Chihli (Hopeh) in 40° N. and 119° 47′ E. It occupies a notably strategic position, commanding the narrow coastal sill between the sea (Gulf of Liao-tung) and the outlying mountain ranges of Jehol, followed by the Great Wall, which was formerly continued to the actual coast. Its historic function has thus been that of a military post, guarding the crucial corridor communicating

between the plain of north China and that of south Manchuria, and so it has come into prominence at different periods,—as at the time of the establishment of the Manchu dynasty in China, during the Boxer Rebellion, and the Sino-Japanese War.

SHANKARSETT, JAGANNATH (1800–1865), the recognized leader of the Hindu community of Bombay for more than forty years, was born in 1800 into a family of goldsmiths of the Daivadnya caste. He was one of the greatest benefactors of Bombay, a pioneer in the provision of schools both for boys and girls, and of higher education for men, and a generous donor to educational institutions. To Jagannath Shankarsett and his public-spirited friends, Sir George Birdwood and Dr. Bhau Daji, Bombay is also indebted for the reconstruction which, beginning in 1857, gradually changed a close network of lanes and streets into a spacious and airy city, adorned with fine avenues and splendid buildings. He was the first Indian to be nominated to the legislative council of Bombay under the Act of 1861. He died at Bombay on July 31, 1865.

SHANKLIN, a watering-place in the Isle of Wight, England, $8\frac{1}{2}$ m. S. of Ryde by rail. Pop. of urban district (1931) 5,071. It is beautifully situated on the cliffs bordering the south-east coast, and is sheltered west by high-lying downs. The old church of St. Blasius is Perpendicular. There are several modern churches and chapels, a pier and a lift connecting the town with the esplanade beneath the cliff. The picturesque winding chasm of Shanklin Chine breaches the cliffs south of the town.

SHANNON, CHARLES HAZELWOOD (1865–), English artist, was born at Sleaford in Lincolnshire in 1865, the son of the Rev. Frederic Shannon. He attended the Lambeth school of art, and was subsequently considerably influenced by his friend Charles Ricketts and by the example of the great Venetians. In his early work he was addicted to a heavy low tone, which he abandoned subsequently for clearer and more transparent colour. He achieved great success with his portraits and his Giorgionesque figure compositions, which are marked by a classic sense of style, and with his etchings and lithographic designs. The Dublin Municipal gallery owns his circular composition "The Bunch of Grapes" and "The Lady with the Green Fan" (portrait of Mrs. Hacon). His "Study in Grey" is at the Munich gallery, a "Portrait of Mr. Staats Forbes" at Bremen, and a "Souvenir of Van Dyck" at Melbourne. His most remarkable pictures include "The Bath of Venus," in the collection of the late Lord Northcliffe. Other portraits are those of his friend Charles Ricketts and of Lillah McCarthy in "The Dumb Wife." Complete sets of his lithographs and etchings have been acquired by the British Museum and the Berlin and Dresden print rooms. He was awarded a first-class gold medal at Munich in 1895 and a first-class silver medal in Paris in 1900. He was elected A.R.A. in 1911 and R.A. in 1921, and is a member of the Society of Twelve, and Associate of the Société nationale des Beaux Arts.

SHANNON, JAMES JEBUSA (1862–1923), Anglo-American artist, was born at Auburn, N.Y., in 1862, and at the age of eight was taken by his parents to Canada. When he was sixteen, he went to England, where he studied at South Kensington, and after three years won the gold medal for figure painting. He soon became one of the leading portrait painters in London. He was one of the first members of the New English Art Club, and in 1897 was elected an associate of the Royal Academy, and R.A. in 1909. He died in London on March 6, 1923.

SHANNON, the principal river of Ireland. It flows with a bow-shaped course from north to south and south-west, from the north-west part of the island to its mouth in the Atlantic on the south-west coast, with a length of about 240 m. and a drainage area of 4,544 sq.m. Rising in co. Cavan in some small pools at the foot of Cuilcagh Mountain, the Shannon crosses co. Leitrim, traversing Lough Allen (9 m. in length), the first of a series of large lakes. It then separates co. Roscommon on the right (W.) bank from counties Leitrim, Longford, Westmeath and Offaly County on the left. In this part of its course it forms Loughs Boderg (7 m. long), Forbes (3 m.) and Ree (18 m.), and receives from the west the river Boyle and from the east the Inny, while in co. Longford it is joined by the Royal Canal. It now separates co. Galway on the right from Offaly County and co. Tipperary; receiving the Suck from the west and the Brosna from the east, and forming Lough Derg (23 m.). Dividing co. Clare from counties Tipperary and Limerick, the Shannon reaches the city of Limerick and debouches upon an estuary 60 m. in length with a direction nearly east and west. This divides co. Clare on the right from counties Limerick and Kerry on the left. A wide branch estuary, that of the Fergus, joins from the north, and the rivers Mulkear, Maigne and Deel enter from the south. From Lough Allen to Limerick, where the Shannon becomes tidal, its fall is 144 ft. With the assistance of short canals the river is navigable for light vessels to Lough Allen, and for small steamers to Athlone; while Limerick is accessible for large vessels. The salmon-fishing is famous; trout are also taken in the loughs and tributary streams. Carrick-on-Shannon, Athlone, Killaloe and Castleconnel are favourite stations for sportsmen. The islands of the loughs are in several cases sites of early religious settlements, while of those on the river-banks the most noteworthy is that of the seven churches of Clonmacnoise.

One of the first matters to engage the attention of the Government of the Irish Free State was the provision of cheap electrical power, and it was decided that power could be most economically produced by the construction of a central generating station capable of utilising the immense resources of the Shannon.

Outline of the Scheme.—The scheme provided for the development of hydro-electric power from the Shannon in three stages —called the partial development, the further development and the full development respectively. In the partial development Lough Derg alone was to be used for storage, but the winter level would not be raised. In the further development the storage in Lough Ree and Lough Allen would be added; and in the full development the storage in Lough Derg would be increased by raising the level of the lake above winter high water level. The head race constructed for the partial development was to be the size necessary for the full development; but the tail race, which is mostly in rock, would be enlarged for the further development.

In the Shannon the period of maximum flow coincides with that of maximum demand, thereby reducing storage requirements. On the other hand, as the fall from Lough Derg to the sea is gradual, it was necessary to construct a long head race in order to obtain an adequate fall. The Siemens-Schückert project (constructional work began in 1925) utilises the total fall of 100 ft. between Lough Derg and Limerick in a single large step, by leading the water out of the river bed into an inlet canal, or head race, to leave the Shannon at Parteen, above O'Brien's Bridge, and to extend a distance of about $6\frac{1}{2}$ m. to Ardnacrusha. Here, as an initial installation, are three vertical Francis turbines each of 38,500 h.p. The water is conducted to the turbines by large steel pipes 20 ft. in diameter and 140 ft. long and carried back to the Shannon in a tail race $1\frac{1}{8}$ m. in length. The electric energy produced in the power station is to be transmitted by means of a high tension network to most of the towns and villages of the Free State with a population of over 500. By means of a network radiating in a closed ring formation from the power-station, Dublin, Cork and Maryborough, all stations will be fed from two directions. A semi-public Board, known as the Electricity Supply Board, has been formed to control the distribution of current. The Board has extensive powers of acquiring existing undertakings and has already acquired the majority of such undertakings.

Cost of the Scheme.—The revised estimate of the cost of the partial development is £5,835,000. The estimated costs of the further and full development are £7,700,000 and £8,000,000 respectively. Provision is made for the advance of £2,500,000 to the Electricity Supply Board for the purpose of constructing the low tension network, wiring houses, and acquiring existing undertakings. The price at which electricity can be supplied to the consumer will depend upon the density of population in the locality and upon the volume of demand. It is estimated that the wholesale price of electric power supplied in bulk at Dublin and Cork should be about 0·6d. and at the end of the 10 kv. lines about 2·5d. Ultimately the current might be supplied at a flat rate, in which case the wholesale price everywhere should be less than

1d. per unit. These figures are considerably less than the costs at the commencement, and the price might be expected continuously to decrease with the growth in the demand for current. It was calculated that the scheme should return from 5½ to 7% upon the invested capital, provided out of public money.

Benefits of the Scheme.—The success of the scheme will depend largely upon the growth of effective demand for current. At first the Free State was very backward in its use of electricity both for industrial and domestic purposes. Both Siemens-Schückert and the experts who advised on the scheme were of opinion that the supply would create a very rapid growth in demand and this hope has been largely realized. Cheap light, heat and power for domestic consumption would be provided; and also power for large and small scale industry, particularly mills and creameries. It was hoped that farmers would use the power to light their premises and to drive farmyard machinery, and that the growth of manufacturing industries of an electro-chemical nature would be stimulated. The electrification of the railway system, apart from those suburban lines with heavy traffic, was not contemplated.

It remains to consider the effects which the Siemens-Schückert Scheme will have on (a) the drainage, (b) the navigation and (c) the fisheries of the Shannon. As regards drainage, it is claimed that the partial development, in which the winter level at Lough Derg will be maintained for about five months of the year, will by reason of the embankments to be erected, save from 3,000 to 4,000 acres of land from annual flooding; and that the later stages of development, in which the storage capacity will be increased and the consequent embankment extended, will save a further large area. The drainage of the Shannon basin will therefore be improved by the scheme. As regards navigation, there have been constructed two locks each 50 feet high to provide a passage from the tail race to the head race. The complete protection of the fisheries from damage is admitted to be impossible, but everything possible has been done or is being done to minimize the injury that will be inflicted; also provision has been made in the scheme for compensation to fishery interests.

BIBLIOGRAPHY.—Full particulars of the Shannon Scheme are to be found in *The Electrification of the Irish Free State; The Shannon Scheme Developed by Siemens-Schückert* and The Report of the Experts appointed by the Government Stationery Office, Dublin; Dail Eireann, Debates, *Official Report*, vol. 10 and 11. *See* also *Electrical Industries* (Aug. 29, 1928); Annual accounts of the Shannon Power Development Fund, and annual reports and accounts of the Electricity Supply Board. SHANSI, an upland province in the interior of north China. It is a link in the girdle of loess-lands which wrap around the edges of the Mongolian plateau and which in effect constitute a belt intermediate between arid pastoral Mongolia and the great plain of north China, one of the foci of Chinese agricultural population. The Shansi plateau rises abruptly from the alluvial plain (relative to which it constitutes the "western mountains" as opposed to Shantung, the "eastern mountains") in the broken limestone edge of the Tai-hang-shan, but passes by much easier gradations into the Mongolian tableland beyond. The plateau surface is not, however, uniform. A series of ridges, arranged in the form of an arc, convex to the north-west, obtrudes from beneath the loess-mantle and, while almost buried in south Shansi, becomes increasingly conspicuous northwards so that in north Shansi the loess-cover is restricted to basins between high mountain ranges. Let down below the general level of the plateau in south Shansi is a chain of alluvial-floored basins strung along the valley of the Fên-ho and continuous with the Wei-ho valley in central Shansi. The largest of the Shansi basins lies at the head of the Fên-ho valley in the very heart of the province and contains Taiyüan-fu, the capital. These basins, being the foci of drainage, are better watered than the porous loess of the plateau above. As the rainfall of Shansi as a whole is marginal (being under 20 inches) and liable to fail, this distinction between basin and plateau is of great importance and the population is mainly concentrated either in the central belt of basins or on the terraces of the Tai-hang-shan which sink into the plains of Chihli (Hopeh) and Honan. The total population was estimated in 1922 at 11,654,879, and that of Taiyüan-fu at 51,363. The bulk of the population is therefore essentially rural.

The loess-basins along the Fên and Wei valleys were the homeland of Chinese agricultural civilization. They offered not only the intrinsic advantages of open unwooded country and a fertile soil but also easy communication with the old oasis cultures of the Tarim basin. It is suggested, indeed, that by way of Central Asia indirect links may have existed with the oldest agricultural centres of all, at Anau and in Babylonia, and the fact that the cereals (wheat, barley and millet) which formed the basis of the agricultural system both in western Asia and in north-west China have been found in a wild state only in the former points to early cultural links between them. It seems probable that the early Chinese acquired first the art of pottery, always closely associated with early agriculture, and later the knowledge of metal from the west, by way of Central Asia. Whether the Wei or the Fên valley was the first to be involved in this early development is a debatable point, but the first dynasty, the Hsia (2205–1766 B.C.) is traditionally associated with the lower Fên-ho valley, and many of the oldest legends belong to it. The Fên-ho valley has thus been under continuous cultivation for fully forty centuries. The conservation of water-supply has always been one of the essentials of agricultural practice in Shansi due to the marginal rainfall and porous loess soil. An elaborate system of agreements between individual farmers in the same village and between villages in the same valley has grown up in order to ensure an equitable distribution of the water-supply. This necessity hastened organization and contributed to the early development of civilization in the loess-lands. The chief crops grown are those cereals—wheat, barley and millet—able to subsist on comparatively small supplies of moisture. It was these which formed the basis of the agricultural system in the very beginning, in the 3rd millennium B.C. Rice, which was not adopted by the Chinese until they had spread out from their original home in the loess-lands into the Yangtze Valley, is cultivated only where the supply of water is sufficiently plentiful to permit the flooding of the fields.

Shansi was not only the home of Chinese agriculture but the centre of the most intense coal-mining activity and the site of the most famous iron industry of the Old China. The greater part of south Shansi consists of a vast coalfield which, though buried underneath loess and sandstone in the centre, crops out in the terraces of the Tai-hang-shan edge, which Richthofen named the "Anthracit-Terrasse." The main seam is here on the average 18 ft. thick and at the base of the coal measures iron ores are interbedded.

From the "Anthracit-Terrasse" there developed an extensive trade not only in lump anthracite with the adjacent parts of the north China plain but also in pig iron and manufactured iron goods, which supplied the whole of the north China market. The two most famous iron-working centres were Pingting and Tsechow.

In modern China the arterial routes of communication with but one exception skirt the edges of but do not penetrate into the province of Shansi, and its old industrial importance has been lessened by coal-mining nearer the coast and by the importation of foreign iron. But in the future Shansi is likely to be penetrated by more railways than the single line at present in existence (the branch to Taiyüan-fu from the Peking–Hankow railway) and, although its iron industry may never revive, its coalfields are the most valuable in all China and will once again be the focus of coal-mining activity. This relative removal, however, at the present day from the turmoil along the main routes has facilitated the gradual transformation of the province which has been effected by Yen Hsi-shan who alone among the provincial governors has remained in office since the 1911 Revolution and has thus been able to carry out a continuous policy. He is known as the "model governor" and Shansi as the "model province." The chief agency in the transformation of the people is the school and Shansi comes nearer than any other province to attaining compulsory school attendance. Over six hundred miles of roads have been built, hill-tops have been planted with saplings, partly for the sake of their timber and partly in order to regularize

the flow of river-water, and the cultivation of several remunerative commercial crops has been encouraged with considerable success. The most important of the latter are cotton, cultivated chiefly in the Fên-ho valley, and the mulberry, which has been planted especially in the south-east overlooking the Hwang Ho plain.

SHAN STATES, a collection of semi-independent states on the eastern frontier of Burma inhabited by the Shan or Tai race. The Shan States had an area of 56,311 sq.m. and a pop. (1921) of 1,433,542. On Oct. 1, 1922 a scheme came into effect for the Federation of the Shan States, along lines proposed by Sir Reginald Craddock. Under this the control of the Federated Shan States is vested solely in the governor and its financial arrangements are separated from those of the province generally. The administration is in the hands of a council of chiefs or *Sawbwas,* with a British commissioner. The Federation is financed partly by a fixed contribution from Government, partly by contributions from the chiefs. The Federation includes the former three divisions of the Northern Shan States (N.S.S), Southern Shan States (S.S.S.) and Karenni. There are besides several Shan States in other parts of Burma and a number beyond the border of Burma, which are tributary to China, though China exercises only a nominal authority. The British Shan States were tributary to Burma and came under British control on the annexation of Upper Burma. They rank as British territory, not as native states. The civil, criminal and revenue administration of each state is vested in the chief, subject to the restriction specified in the *sanad* or order of appointment granted to him.

Physical Features.—The shape of the Shan States is roughly that of a triangle, with its base near the plains of Burma and its apex on the Mekong river. The Shan plateau is properly only the country between the Salween and Irrawaddy rivers. On the west it is marked by the line of hills running from Bhamo to the plains of Lower Burma. On the east it is defined by the rift of the Salween. The average height of the plateau is between 2,000 and 3,000 ft., but it is seamed and ribbed by mountain ranges, which split up and run into one another. On the north the Shan States are barred across by ranges following the line of the Namtu. The huge mass of Loi Ling, 9,000 ft., projects south from this and from each side of it and to the south is the wide plain extending to Möng Nai. The highest peaks are in the north and the south. Loi Ling is the highest point west of the Salween, and in Kokāng and other parts of north Hsenwi there are many peaks above 7,000 ft. The majority of the intermediate parallel ranges have an average of between 4,000 and 5,000 ft. with peaks rising to over 6,000. The country beyond the Salween is a mass of broken hills, ranging in the south towards the Menam from 2,000 to 3,000 ft., while in the north towards the Wa states they average from 5,000 to 7,000. Several peaks rise to 8,000 ft., such as Loi Maw (8,102). From December to March it is cool everywhere, and 10° of frost are experienced on the open downs. The hot season temperature is 80° to 90°, rising to 100° in the Salween valley. The annual rainfall varies from 60 in. in the broader valleys to 100 on the higher mountains.

Race and Language.—In 1921 there were 1,017,987 Shans in Burma. The Thai or Tai, as they call themselves, were first known to the Burmese as Tarôks or Tarets. The original home of the Thai race was S.W. China. It is probable that their first settlement in Burma proper was in the Shweli valley, and that from this centre they radiated at a comparatively recent date north, west and south-east, through Upper Burma into Assam. It is supposed that the Thai race boasts of representatives across the breadth of Indo-China; that it numbers among its members not only the Shans proper, the Laos and the Siamese, but also the Muongs of French Indo-China, the Hakas of S. China, and the Li, the inhabitants of the interior of the far Eastern island of Hainan in the China seas.

The Thai language may be divided into two sub-groups, the North and the South. The South includes Siamese, Lao, Lü and Hkün; the North, the three forms of Shan, namely North-Burmese Shan, South-Burmese Shan and Chinese Shan with Hkamti and Ahom. The vernacular of the people who are directly known in Burma as Shan is South-Burmese Shan. This language is isolating and polytonic. It possesses five tones, a mastery of which is a *sine quâ non* if the language is to be properly learnt. It is exhaustively described in the works of Dr. Cushing.

The Shans are a peaceful race, fond of trading. During the past 25 years the trade with Burma has increased very largely, especially after the construction of the Lashio and Heho railways. The huge silver-lead-zinc mines of the Burma Corporation at Bawdwin lie in the Northern Shan States. The cultivation of wheat and potatoes in the South States promise them wealth also when a railway furnishes them means of getting the produce out of the country. Since 1893 the peace of the Shan States has been practically undisturbed.

See Ney Elias, *Introductory Sketch of the History of the Shans in Upper Burmah and West Yun-nan* (Calcutta, 1876); Cushing, *Shan Dictionary* (Introduction); Bock, *Temples and Elephants;* Sir A. Phayre, *History of Burmah;* A. R. Colquhoun, *Across Chrysê* (London, 1883), and *Amongst the Shans* (1885); Diguet, *Étude de la langue Thai* (Paris, 1896).

The Southern Shan States number 36 with a total area of 36,154 square miles and a population in 1921 of 836,220. The largest is Tũng Kēng (12,400 sq.m., pop. 208,755); the smallest has an area of only 14 sq.m. The Northern Shan States are six in number:—Hsipaw (4,400 sq.m., pop. 131,410); Tawngpeng (778 sq.m., pop. 41,255); North Hsenwi (6,335 sq.m., pop. 222,191); South Hsenwi (2,281 sq.m., pop. 84,141); Manglün (2,800 sq.m., pop. 57,318); Möng Mit (3,561 sq.m., pop. 56,498). For the Karen States, *see* KARENNI.

Among the Southern group of States the following are the more important:

TŨNG KĒNG is the most extensive of the Shan States in the province of Burma. The state is known to the Chinese as Mêng Kêng, and was frequently called by the Burmese "the 32 cities of the Gôn" (Hkön), Tũng Kēng has expanded considerably since the establishment of British control, by the inclusion of the districts of Hsen Yawt, Hsen Mawng, Möng Hsat, Möng Pu, and the cis-Mekong portions of Kēng Cheng, which in Burmese times were separate charges. The "classical" name of the State is Khemarata or Khemarata Tungkapuri. About 63% of the area lies in the basin of the Mekong river and 37% in the Salween drainage area. Some peaks rise to over 7,000 ft.; the elevation is nowhere much below 5,000 feet. There are successive parallel hill ranges running north and south. Mountainous country predominates. The chief rivers, tributaries of the Salween, are the Nam Hka, the Hwe Lông, Nam Pu and the Nam Hsīm. The first and last are considerable rivers. Rocks and rapids make both unnavigable, but much timber goes down the Nam Hsīm.

Teak forests exist in Möng Pu and Möng Hsat, and also in the Mekong drainage area in the south of the State, but there is only a local market for the timber. Rice, as elsewhere in the Shan States, is the chief crop. Next to it is sugar-cane. Earth-nuts and tobacco are the only other field crops in the valleys. On the hills, besides rice, cotton, poppy and tea are the chief crops. The tea is carelessly grown, badly prepared, and only consumed locally. Much garden produce is raised in the valleys. The State is rich in cattle, and exports them to the country west of the Salween. As in all parts of the Shan States, there are huge areas awaiting development.

Tũng Kēng, the capital, is surrounded by a brick wall and moat about 5 m. round. Only the central and northern portions are much built over.

MÖNG NAI is second in size among the Southern States (3,100 sq. m., pop. [1921] 55,647), and lies with Möng Pan and Mawkmai in the south-west.

MÖNG PAN ranks next to Tũng Kēng and Möng Nai in size among the Southern Shan States, with an area of 2,988 sq.m., and a pop. (1921) of 21,728. The main State lies, except for a few insignificant circles, entirely west of the Salween. The only considerable area of flat land is round the capital, which lies in a large and fertile plain, marking roughly the centre of the State. From this plain rise low hills covered with scrub jungle, sloping up to ranges of about 5,000 ft. on nearly every side. Rice is the only crop, irrigated where possible; elsewhere dry cultivation prevails. The State has valuable teak forests, which cover a considerable

but undetermined area. The general altitude of the valleys is about 2,000 feet. The capital is small, and has only about 200 houses.

LAWKSAWK has an area of 2,362 sq.m. and a pop. of 28,010 and ranks fourth in size among the States of the southern division. The crops are rice, sesame, cotton, ground-nuts and oranges. The State is mountainous. To the north the country falls away to the Nam Tu (Myit-ngè), where there are teak forests, as well as along the Nam Lang and Nam Et, which with the Zawgyi form the chief rivers. Most of them disappear underground which makes the extraction of timber impossible except for local use. Lawksawk is the capital. The old brick walls and the moat are falling into decay.

MŌNG PAI (called Mobyē by the Burmese), is the most south-westerly of the Shan States. It has an area of 73 sq.m., and a pop. (1921) of 20,996. The country is hilly, rising westwards from the chief stream, the Nam Hpilu or Balu. This is navigable for native boats throughout the year to the point where it sinks underground in Karen-ni. The chief cultivation is rice, with about two acres of dry or hill rice to one of wet bottom. The hill fields are left fallow for ten years after two years' cultivation.

Other States in the southern group with an area of more than 1,000 sq.m. include: Mawkmai (2,200 sq.m.), Mōng Nawng (1,646), Mōng Kūng (1,593), Lai Hka (1,560), Yawnghwe (1,302) and Loilong (1,084).

TAUNG-GYI is the chief town of the Shan States and the meeting place of the Council of Chiefs. It is situated in 96° 58′ E. and 20° 47′ N., at an altitude of about 5,000 ft., in a depressed plateau on the crest of the Sintaung hills. It is in the State of Yawnghwe, a few miles by motor road from the present terminus of the Southern Shan States railway which joins the main Rangoon-Mandalay line at Thazi. The five-day bazaar is the trading place of the natives. A special quarter contains the temporary residences of the chiefs when they visit headquarters, and there is a school for their sons.

Among the northern group of States, of which North and South Hsenwi, Hsipaw and Mang Lön are the chief.

HSENWI or THEINNI is better known by the Burmanized name of Theinni. The northern part of North Theinni is a mass of hills, in the valleys between which are numerous tracts under rice cultivation. The southern portion has much more flat land, along the line of the Nam Tu, its tributaries the Nam Yao and the Nam Nim, and the Nam Yek flowing into the Salween. This was formerly thickly populated, and still remains the most valuable portion of the State. Both north and south of the Nam Tu there are many peaks which rise to 6,000 ft., and several over 7,000 feet. The northern portion (about 4,000 ft.) might be called a plateau. It has large, grassy, upland downs. This part of the State has fallen almost entirely into the hands of the Kachins. The Shans are found in the Nam Mao (Shweli or Lung Kiang) valley, and in the Nam Tu and other valleys in the southern part of the State. South Theinni is bisected by the huge mass of Loi' Ling, nearly 9,000 ft. above sea-level. Apart from this it consists of broken hill-country or downs, the latter chiefly in the eastern half of the State. It is watered by numerous streams, of which the chief is the Nam Pang, an affluent of the Salween. Considerable deposits of coal, or rather of lignite, exist in both North and South Theinni, but have as yet been little worked. Gold is washed in many of the streams in a fitful way. No valuable timber exists to any considerable extent. Pine forests cover some of the ranges, but, as elsewhere in the Shan States, varieties of the oak and chestnut are the commonest forest trees. The climate as a whole is temperate. The average rainfall is about 60 in. yearly. It has regained much population since the British occupation in 1888, and especially since the opening of the Mandalay Lashio Railway and the Burma Corporation's mine and smelting works.

Hsenwi, the capital of North Hsenwi, stands near the north bank of the Nam Tu. The ruins of the old capital lie at a short distance, and show it to have been a large and well-built town. Mōng Yai is the capital of South Hsenwi, with a population of about 2,000. The races found in Hsenwi comprise Shans, Kachins, Chinese, Burmese, Lihsaws, Wa, Palaungs and Yanglam. The Shans and Kachins predominate, and are nearly equal in numbers.

LASHIO, the chief town of the northern Shan States, lies in the state of North Hsenwi, situated in 22° 56′ N. and 97° 45′ E. at an altitude of 3,100 ft., on a low spur overlooking the valley of the Nam Yao. It is the terminus of the Mandalay-Kun Lông railway and of the government cart road from Mandalay, from which it is 178 m. distant.

HSIPAW or THIBAW is called by the Shans, and officially, Hsipaw, and also frequently Ōng Pawng (the name of an old capital). The chief plain land is in the valley of the Nam Tu (Myit-ngè), near Thibaw town, and the valley or strath of the Pyawng Kawng, Nawng Ping neighbourhood. Elsewhere the valleys are insignificant. The hills on the Möng Tung border reach their highest elevations in the peaks Loi Pan (6,848 ft.) and Loi Htan (6,270 ft.). To the north-west of Thibaw town, on the Tawng Peng border, Loi Lam rises to 6,486 ft. The valley of the Nam Tu marks the lowest point in the State at Thibaw town, about 1,400 ft., and rises on the east in Möng Tung to a plain level of about 2,500 ft., and on the west in Möng Lông to a mass of hills with an average height of 4,500 ft., broken up by the Nam Yawn and Nam Kaw valleys, which are about 3,000 ft. above sea-level.

The chief river is the Nam Tu or Myit-ngè. Between Thonzè and Lawksawk (Yatsauk) it flows through a gorge between cliffs 3,000 to 4,000 ft. high. At the gorge of Gôkteik the Nam Htang and the Nam Pasè unite to form the Nam Küt, which passes into the ground at the natural bridge where the Mandalay-Lashio railway crosses the gorge, and reappears to join the Nam Tu. The bed of the Nam Küt is about 1,500 ft. below the general level of the country. Coal of poor quality is found at various places. The average maximum temperature at the beginning of April is about 96°, and the minimum about the same period 65°. The rainfall averages about 70 in. The chief crops are rice, cotton, sesame, tea in the hills, and *thanat,* the leaf of a tree used for the wrapper of the Burma, or "green" cheroot. Cotton cloth was formerly much more generally manufactured than it now is, and a coarse country paper is also made. The government cart road to Lashio passes through the centre of the State, and the Mandalay-Lashio railway also passes through the capital. Teak forests exist along the banks of the Nam Tu and in the Mang Lön States, but both have been practically exhausted, and will have to be closed for many years.

MANG LÖN, is the chief state of the Wa or Vü tribes, some of whom are or were till very recently head-hunters, and Mang Lön is the only one which as yet has direct relations with the British government. The State extends from about 21° 30′ to 23° N., or for 100 m. along the river Salween. Its width varies from a mile or even less on either side of the river to perhaps 40 m. at its broadest part near Taküt, the capital. It is divided into East and West Mang Lön, the boundary being the Salween. There are no Wa in West Mang Lön. Shans form the chief population, but there are Palaungs, Chinese and Yanglam, besides Lahu. The bulk of the population is Wa, but there are many Shans and Lahu. The only flat land is along the banks of streams in the valleys. Here the Shans are settled. There are prosperous settlements and bazaars at Nawng Hkam and Möng Kao in West Mang Lön. The Wa of Mang Lön have given up head-hunting, and many profess Buddhism. The capital, Taküt, is on a hill-top 6,000 ft. above sea-level. The sawbwa is a Wa, and has control over two sub-states, Mōt Hai to the north and Maw Hpa to the south.

See under BURMA, also the Report on the Administration of the Shan and Karenni States (annual).

SHANTUNG, a northern maritime province of China, consisting of a mountainous peninsula of much indented coastline projecting eastward into the Yellow sea, but separated from the other highlands of China by the wet alluvial plain of the Hoang-ho. That river has changed its course many times. Prior to 1851 it reached the sea south of the highland of Shantung; since about 1853 it has flowed north of the highland, but not always in the same bed. The province includes a considerable belt of the alluvial plain west and north of the highland, but less of it on the south. The main direction of the mountain lines is

west-south-west to east-north-east, as in Liaotung, and siliceous schists form a great part of the masses concerned, while in the granite and gneiss, the direction N. 30° W.–S. 30° E. is more evident. The Tai-shan, on the north side of Shantung, west of Chefoo, gives a steep coast facing the Gulf of Pe-chih-li. These hills are marked off from those of the south-east coast by a relatively low line from Chefoo to Tsingtao. At the base of the peninsula, hill lines, in which both directions are exemplified, gather around the Tai-shan, the culmination of which is 5,060 ft. above sea-level. This mountain is one of the chief centres of pilgrimage in China, and has been famed in this way from immemorial antiquity. It was von Richthofen's opinion that Shantung was very early occupied by cultivators spreading from the Wei valley, and that here, once the barbarians were subdued, they had opportunities of defence as well as of economic development; in this way he thinks Shantung came to play a special rôle in Chinese life, a rôle greatly enhanced by the fact that Confucius (551–479 B.C.) and Mencius were natives of the province. The Tai-shan has sanctuaries of many kinds, and pilgrims visit them, especially in spring. The Tai-shan is divided from the mountains of the peninsula by the low line of the Kiau-ho; the other rivers of the highland region are mostly short, but across the plain to the north there run several streams which interlace to some extent; the largest is called Wei-ho. South-west of the mountain system runs the Grand canal, which receives the I-ho from the Tai-shan. The rainfall at Chefoo is about 29 in. per annum, the autumn being driest; the mean monthly temperature here varies from 25·3° in January to 80° in August. The climate on the slopes facing south-east is considerably warmer. The heights still shelter wild boars and wolves, and the trees in the colder regions include pines, oak, poplar, willow, with some cypress. The valleys in the mountain region are often fertile, but the hills themselves are barren. Millet, wheat, barley, sorghum, maize, peas, cotton, hemp and poppies are, or have been, cultivated, with castor-oil and rice in the south. Fruit trees are numerous and specially rich in parts of the south. The wax tree grows in the east, and the wax insects are placed on it for the summer, being taken indoors in the autumn to void the substance whence wax is prepared. They are protected indoors during the winter. Shantung produces both ordinary silk and the silk made by a caterpillar which lives on oak leaves. There are many mules and horses, as well as sheep, cattle, goats, etc. The province is famed for its minerals. Coal occurs at I-chow-fu (south), I-hien (south-west), Lao-fu (centre), and Wei-hien (north). About two million tons of bituminous coal were produced in 1922 in the province, and there are considerable reserves of the material. Production of iron ore has been small, but there are large reserves, estimated to yield some 14 million tons of iron when worked. Gold is produced here and there, and there is some copper, lead, etc.

The area of the province is estimated at 56,000 sq.m., and its population at anything between 25 and 38 million. Britain obtained a lease of Wei-hai-wei, near the eastern end of the peninsula, and Germany a lease of Kiao-chow (port Tsingtao) in 1898. The Japanese captured the latter in 1914 and it was returned to China in 1922. Negotiations for the return of Wei-hai-wei were begun in 1921. The towns of Shantung include Chinan (Tsi-nan) at the northern foot of the Tai-shan, the capital and largest city; Tsaochow, in the south-west; Tsining, on the Grand canal; I-chow, in the south; Wei-hien, in the north; and Chefoo, the treaty port, on the north coast, all probably above the 100,000 line in population. The lowland portions of the province are among the most densely-peopled regions in China. The railways of the province include a long section of the Tientsin-Pukow main line, while a railway, originally German, leaves this line at Chinan and goes to Tsingtao; there are also branch lines and others are planned. The province under the empire was divided into ten prefectures.

See F. von Richthofen, *China*, vol. ii. (1882); L. Richard, *Géographie de l'Empire de Chine* (Shanghai, 1905); Anon., *The Christian Occupation of China* (Shanghai, 1922); ed. H. G. W. Woodhead, *The China Year Book*, Tientsin and London, annual; ed. S. Cooling, *Encyclopaedia Sinica* (1918).

Political History.—The province of Shantung obtained an international reputation during the years immediately following the World War, owing to the difficulties attending the rendition of the Kiao-Chow territory seized by Germany in 1897. The territory remained in the hands of the Germans, who spent large sums of money improving and developing the colony, until Nov. 1914, when it was captured by the Japanese. The Treaty of Versailles confirmed Japan in the possession of the territory, but the Chinese were thoroughly dissatisfied with the decision. At the time of the Washington Conference Japan agreed to hand back her holdings to China, under conditions, however, which still gave the Japanese an acknowledged interest in the province. During the recent civil war banditry has been rife. In 1928 Japanese troops clashed with the Chinese Nationalist forces in Tsinanfu and a tense situation developed which up to 1929 had been only partially relieved.

See Forsyth, *Shantung* (1902) and Willoughby, *China at the Conference* (1922).

SHANTUNG. A plain silk fabric of light texture originally produced in the Chinese province of that name from a variety of native silk known as "pongee" silk obtained from the cocoons of wild silkworms that feed on oak leaves. Hence, "pongee" is of a strong and rough type of silk with a light tan natural colour and a coarser filament structure than that produced by cultivated silkworms that are fed on mulberry leaves.

Japanese "pongee" is also a type of wild silk of a similar character to Shantung silk, but of a smoother and more even filament structure than that of Chinese "pongee." The word "pongee" is said to correspond with "homespun," "hand-spun," and "hand-woven," as it is chiefly conducted on a very large scale as a home or domestic industry both in China and Japan, although "pongee" silk or Shantung is now woven on power looms.

"Tusser" silk is the name applied to a type of low grade fabric produced from silk spun by a species of wild native silkworms of India, and possessing characteristics similar to those of Chinese "pongee" silk. Fabrics produced from "pongee" or other types of wild silk partake of the physical characteristics of such silk and feel somewhat harsh and rough, although the better qualities of these wild silks are said to be of a more durable character and to wear better than silk fabrics produced from the products of cultivated silkworms.

Shantung silk fabrics are also sometimes sold under the trade-name of "Ninghai." (H. N.)

SHANTY or **CHANTY,** a song of the class of labour songs which sailors on merchant ships sing as they pull ropes to hoist yards and sails, raise anchors or work pumps. The word "shanty," however it is spelt, is usually thought to be the British sailor's corruption of the French word "chanter" and to come from the French Canadian lumbermen, who sing as they haul their logs; Sir Richard Terry derives it from the West Indian negroes, who move their huts or "shanties" with ropes and sing as they work, with a shantyman as soloist and leader.

On board ship there are two kinds of shanties, one for pulling ropes, and one for winding the capstan. The former kind provides in the tune points for collective pulls (or a simple final pull on the last note, as in "bunting" a sail), the latter for continuous rhythmical movement. Among the best known tunes are those of "Shanadar" (or Shenandoah), "Rio Grand," "Clear the track, let the bullgine run," "Knock (or 'blow') the man down," "A-roving," "Heave away my Johnnie," "O Johnny come to Hilo," and "Whoop (or 'whip') Jamboree," to name but a few.

See Cecil Sharp, *English Folk-Chanteys;* R. R. Terry, *Shanty Book* (2 vols.), and Grove's *Dictionary of Music.*

SHAPING MACHINES: *see* PLANING MACHINES.

SHAPUR (Pahlavi, *Shāhpuhre,* "son of the king"; Greek *Sapores,* commonly *Sapor*), the name of three Sassanian kings.

1. SHAPUR I. (A.D. 241–272), son of Ardashir I. The Persian legend which makes him the son of an Arsacid princess is not historical. Ardashir I. had towards the end of his reign renewed the war against Rome; Shapur conquered the Mesopotamian fortresses Nisibis and Carrhae and advanced into Syria; but he was driven back by C. Furius Timesitheus, father-in-law of the

young emperor, Gordianus III., and beaten at Resaena (243). Shortly afterwards Timesitheus died, and Gordianus (*q.v.*) was murdered by Philip the Arabian, who concluded an ignominious peace with the Persians (244).

When the invasion of the Goths and the continuous elevation of new emperors after the death of Decius (251) brought the Roman empire to utter dissolution, Shapur resumed his attacks. He conquered Armenia, invaded Syria and plundered Antioch. At last the emperor Valerianus marched against him, but suffered near Edessa the fate of Crassus (260). Shapur advanced into Asia Minor, but was beaten by Ballista; and now Odaenathus (Odainath), prince of Palmyra, rose, in his rear, defeated the Persian army, reconquered Carrhae and Nisibis, captured the royal harem, and twice invested Ctesiphon (263–265). Shapur was unable to resume the offensive; he even lost Armenia again. But according to Persian and Arabic traditions, which appear to be trustworthy, he conquered the great fortress of Hatra in the Mesopotamian desert; and the great glory of his reign was that a Roman emperor was by him kept prisoner to the day of his death.

In the valley of Istakhr (near Persepolis), under the tombs of the Achaemenids at Nakshi Rustam, Shapur is represented on horseback, in the royal armour, with the crown on his head; before him kneels Valerian, in Roman dress, asking for grace. The same scene is represented on the rocks near the ruins of the towns Darabjird and Shapur in Persis. Shapur left other reliefs and rock inscriptions: one, at Nakshi-Rajab near Persepolis, is accompanied by a Greek translation; here he calls himself "the Mazdayasnian (worshipper of Ahuramazda), the god Sapores, king of kings of the Aryans (Iranians) and non-Aryans, of divine descent, son of the Mazdayasnian, the god Artaxares, king of kings of the Aryans, grandson of the god-king Papak." Another long inscription at Hajjiabad (Istakhr) mentions the king's exploits in archery in the presence of his nobles.

From his titles we learn that Shapur I. claimed the sovereignty over the whole earth, although in reality his domain extended little farther than that of Ardashir I. Shapur built the great town Gundev-Shapur near the old Achaemenian capital Susa, and increased the fertility of this rich district by a barrage through the Karun river near Shushter, which was built by the Roman prisoners and is still called Band-i-Kaisar, "the mole of the Caesar." Under his reign the prophet Mani, the founder of Manichaeism (*q.v.*) began his preaching in Persia, and the king himself seems to have favoured his ideas.

For the monuments and inscriptions *cf.* Sir R. Ker Porter, *Travels;* Flandin and Coste, *Voyage en Perse;* Stolze, *Persépolis;* Thomas, *Journal R. Asiat. Soc.*, new series, iii., 1868: West in *Grundriss der iranischen Philologie*, ii. 76 f.; Dittenberger, *Orientis Graeci inscr.* i., No. 434. A gem with the portrait of the king is in the museum of Gotha, *cf.* Pertsch, *Zeitsch. d. deutschen morgenl. Ges.* xxii. 280.

2. Shapur II. (310–379). When King Hormizd II. (302–310) died, the Persian magnates killed his eldest son, blinded the second, and imprisoned the third (Hormizd, who afterwards escaped to the Romans); the throne was reserved for the unborn child of one of the wives of Hormizd. This child, named Shapur, was therefore born king; the government was conducted by his mother and the magnates. But when Shapur came of age, he turned out to be one of the greatest monarchs of the dynasty. Under his reign the collection of the *Avesta* was completed, heresy and apostasy punished, and the Christians persecuted. This was the natural oriental reaction against the transformation of the Roman empire into a Christian empire by Constantine. In 337, just before the death of Constantine, Shapur broke the peace concluded in 297 between Narses and Diocletian, which had been observed for forty years, and a war of twenty-six years (337–363) began. Shapur attempted with varying success to conquer the great fortresses of Roman Mesopotamia, Singara, Nisibis (which he invested three times in vain), Amida (Diarbekr). The emperor Constantius II. was always beaten in the field. Nevertheless Shapur made scarcely any progress; the military power of his kingdom was not sufficient for a lasting occupation of the conquered districts. At the same time he was attacked in the E. by nomad tribes, among whom the Chionites are named. After a prolonged struggle they were forced to conclude a peace, and their king, Grumbates, accompanied Shapur in the war against the Romans. Shapur now conquered Amida after a siege of seventy-three days (359), and took Singara and some other fortresses in the next year.

In 363 the emperor Julian, at the head of a strong army, advanced to Ctesiphon, but was killed. His successor Jovian was defeated and made an ignominious peace, by which the districts on the Tigris and Nisibis were ceded to the Persians, and the Romans promised to interfere no more in Armenia. In the rock-sculptures near the town Shapur in Persis (Stolze, *Persépolis*, pl. 141) the great success is represented; under the hoofs of the king's horse lies the body of an enemy, probably Julian, and a suppliant Roman, the emperor Jovian, asks for peace.

Shapur now invaded Armenia, took king Arsaces III. (of the Arsacid race), the faithful ally of the Romans, prisoner by treachery and forced him to commit suicide. He then attempted to introduce Zoroastrian orthodoxy into Armenia. But the Armenian nobles resisted him successfully, secretly supported by the Romans, who sent King Pap, the son of Arsaces III. into Armenia. The war with Rome threatened to break out again; but Valens sacrificed Pap and caused his assassination in Tarsus, where he had taken refuge (374). Shapur had conducted great hosts of captives from the Roman territory into his dominions, most of whom were settled in Susiana. Here he rebuilt Susa, after having killed her rebellious inhabitants, and founded some other towns. He was successful in the east, and the great town Nishapur in Khorasan (E. Parthia) was founded by him.

3. Shapur III. (383–388), son of Shapur II., elevated to the throne by the magnates against his uncle, Ardashir II., and killed by them after a reign of five years. He concluded a treaty with Theodosius the Great. (Ed. M.)

SHARES. A share is tangible evidence of the fact that the holder has invested money in a given company, and is also the means of defining the extent of his holding as against those of his fellow-shareholders. In England, a share always has a definite nominal or face value, such as "one pound," "ten shillings," or even "one shilling." The size of a man's holding is measured in "so many shares," and shares are issued, bought and sold by number. This is the vital distinction from stock (*q.v.*) which is always measured by its nominal or face value. Thus a holding of stock is described, for example, as "£100 stock"; a holding of shares as "100 £1 shares." Furthermore, stock is dealt in in odd amounts, *e.g.*, "100.3s.4d. stock"; shares must always be dealt in in multiples of a share—thus a sale of "$\frac{3}{4}$ share" or "$101\frac{1}{2}$ shares" is not permitted.

Interest or dividend payable on shares is expressed in one of two ways—"a dividend of sixpence (or other sum) per share," or "a dividend of 5 (or so much) %," the latter meaning a dividend equivalent to the percentage named on the face value of each share. If the shares are £1 shares, 5% is equivalent to 1s. per share, but if they are 10s. shares, 5% is equivalent to 6d. per share.

The market value of shares has no connection with their nominal value. It is governed by price, which is always expressed in so many pounds, shillings or pence per share. Thus:—

$3\frac{1}{4}$	means	£3.5s.	cash per share.
11/6	"	11s.6d.	" " "
/6	"	6d.	" " "

This is the usual stock exchange way of publishing prices. The presence of fractions and the absence of the stroke implies pounds; otherwise it is shillings and pence.

A company increases its capital by issuing additional shares. They may be issued either free as a complete bonus to shareholders (*e.g.*, two bonus shares for every three held), or at a price below their current market price as a partial bonus to shareholders (*e.g.*, if the market price of outstanding £1 shares is 4, they may be issued at $2\frac{1}{4}$, each holder of two shares being entitled to buy one new, or to sell his right in the market to anyone who will buy it), or at the full market price direct to the public. Con-

versely, if the capital of a company has to be written down—*i.e.*, reduced, this is done by reducing the nominal value of each share, *e.g.*, a company with shares of £1 each might write them down to ten shillings each. Occasionally shares are "split"—*i.e.*, a company whose shares were originally of £10 each might split each share into ten of £1 each, thus increasing the saleability of the shares.

Shares usually represent capital as opposed to loans and debentures. (*See* STOCKS.) They take three main forms: preference, ordinary, and deferred.

Kinds of Shares.—Preference shares usually receive only a fixed rate of dividend, although occasionally they share with the ordinary shares in any further profits. They are then called "participating preference shares." Usually in this case, the ordinary shares get a definite dividend for themselves, and the participating preference shares only receive a share of what is left. In all cases, preference shares rank ahead of ordinary and deferred shares, both as to dividend and as to repayment in the event of liquidation. Thus, if a company earns £100,000 and the preference dividend (say 5% on 2,000,000 £1 preference shares) requires the full £100,000, the holders of the ordinary shares get nothing. If preference shares are "cumulative" any arrears of dividend on them are carried forward and accumulated until a profit is earned. Then all the arrears must be paid off, before anything is paid on the ordinary shares; otherwise, once a preference dividend is not paid, the shareholders have no claim in respect of that dividend upon any future profits.

Ordinary shares rank after preference shares, but whereas the preference shareholder (unless "participating") is only entitled to a fixed dividend and to the return of the nominal value of his shares in the case of liquidation, in both cases the ordinary shareholder receives "what is left." If, however, the company has also issued deferred shares, the ordinary shareholder only gets a fixed rate of dividend, perhaps with participating rights, and the deferred shareholder receives "what is left."

It is not usual for a company to issue all three kinds of shares. Usually it only issues two of the three kinds. When the first and third are issued, they are often called "preferred ordinary" and "deferred ordinary." In no case are directors bound to declare any dividend, even if profits have been earned. (*See* also INVESTMENTS; STOCKS; TRANSFERS.) (N. E. C.)

United States.—In the United States the term "stock" is used to denote the ownership or owned capital in a business, just as the word "shares" is used in England, and the term "share" is reserved to denote one of the units or divisions of this ownership. For a full discussion of American usage *see* STOCK.

SHARI, a river of North-Central Africa, carrying the drainage of a large area into Lake Chad. Its headstreams rise on the watersheds between the Chad basin and those of the Nile and Congo. The principal headstream, known generally as the Wam, rises, in about 6° 30′ N., 15° E., in mountainous country forming the divide between the Chad system and the basin of the Sanga affluent of the Congo. From the source of the Wam to the mouth is a distance, following the windings of the stream, of fully 1,400 m.

The Wam flows east and then north and in about 7° 20′ N., 18° 20′ E. is joined by the Fafa, a considerable stream rising east of the Wam. The upper course of the Wam is much obstructed by rapids, but from a little above the Fafa confluence it becomes navigable. Below the confluence the river, now known as the Bahr Sara, receives three tributaries from the west. In about 9° 20′ N., 18° E., it is joined by the Bamingi, which is formed by the junction of the eastern headstreams of the Shari. One of its branches, the Kukuru, rises in about 7° N., 21° 15′ E. Some 90 m. from its source the Bamingi becomes navigable, being 12 ft. deep and flowing with a gentle current. In 8° 42′ N. it receives on the west bank the Gribingi, a river rising in about 6° 20′ N. It is narrow and tortuous with rocky banks and often broken by rapids. It flows in great part through a forest-clad country. A few miles above its confluence with the Bahr Sara the Bamingi receives on the right hand another large river, the Bangoran, which rises in about 7° 45′ N. and 22° E., in a range of hills which separates the countries of Dar Runga and Dar Banda, and, like the Bamingi, flows through open or bush-covered plains with isolated granite ridges.

Below the junction of the Bahr Sara and the Bamingi the Shari, as it is now called, becomes a large river, reaching, in places, a width of over 4 m. in the rains; while its valley, bordered by elevated tree-clad banks, contains many temporary lakes and back-waters. In 9° 46′ N. it receives the Bakare or Awauk (Aouk) from the east, known in its upper course as the Aukadebbe. This, like the Bahr es Salamat, which enters the Shari in 10° 2′ N., traverses a wide extent of arid country in southern Wadai, and brings no large amount of water to the Shari. In 10° 12′ a divergent branch, the Ergig, leaves the main stream, only to rejoin it in 11° 30′.

In 12° 15′ N. and 15° E. the Shari receives on the west bank its largest tributary, the Logone, the upper branches of which rise far to the south between 6° and 7° N. The principal headstreams are the Pende and the Mambere. Its system is connected with that of the Benue (*see* NIGER) by the Tuburi Swamp, which sends northward a channel joining the Logone in about 10° 30′ N. Below the Logone confluence the Shari, here a noble stream, soon splits up into various arms, forming an alluvial delta, flooded at high water, before entering Lake Chad.

The existence of the Shari was made known by Oudney, Denham and Clapperton, the first Europeans to reach Lake Chad (1823). In 1852 Heinrich Barth spent some time in the region of the lower Shari and Logone, and in 1872–1873 Gustav Nachtigal studied their hydrographical system and explored the Gribingi, which he called the Bahr el Ardhe. But the most prominent explorers have been Frenchmen. In 1896 Émile Gentil reached the Bamingi and in a small steamer passed down the river to its mouth. In 1907 an expedition under Captain E. Lenfant followed the Wam-Bahr Sara from its source to the confluence with the Bamingi and showed it to be the true upper course of the Shari. The same expedition also discovered the Pende tributary of the Logone. From the mouth of the Shari in Lake Chad there is a current towards the Bahr-el-Ghazal channel at the south-eastern end of that lake (*see* CHAD). This channel has been supposed to be a dried-up affluent of the lake. Investigations by the French scientists E. F. Gautier and R. Chudeau led Chudeau to the conclusion that the Shari did not end in Lake Chad, but, by way of the Bahr-el-Ghazal, passed between Tibesti and Ennedi and ended in some *shat* in the Libyan desert. The major part of the Shari basin is in French Equatorial Africa; some of the western affluents are in the Cameroons.

See the works of Barth, Nachtigal and other travellers, especially Lenfant's *La Découverte des grandes sources du centre de l'Afrique* (1909).

SHARK, the name generally given to the larger kinds of Selachians (*q.v.*) of the order Pleurotremi, the smaller kinds being known as dog-fishes. Typical sharks are active and piscivorous, swimming near the surface in warm seas, and are generally bluish or greyish in colour; the body is of the normal fish shape, the snout pointed, the crescentic mouth placed on the under side of the head, and there is a series of separate gill-openings on each side; the teeth are often sharp-edged and triangular; the fins are pointed and the end of the tail is strongly upturned. Owing to the position of the mouth a shark may have to turn over to seize a man swimming at the surface, but this is not its normal method of feeding. Some large pelagic sharks have minute teeth and feed on plankton, and among those that live at the bottom there are many divergences from the type described above; they are generally less active, and have rounded fins and the end of the tail less upturned; some are stout and blunt-headed, others flattened, others eel-like; many are spotted, banded or marbled. The mouth of these bottom-living forms is often transverse, and their teeth are often small and cuspidate, but cutting, piercing and crushing teeth occur. The spiracles, vestigial gill-openings placed behind the eyes, are small in pelagic sharks, but larger in the bottom-living forms, in some (*Squatina, Orectolobus*) as large as in the rays.

To the family Lamnidae belong several large pelagic sharks, widely distributed in warm seas. One of the largest, swiftest, and most voracious is the great white shark or man-eater (*Carcharo-*

don), which reaches a length of 40 ft.; this is somewhat similar in form to a tunny, the body being stout and rounded, the snout pointed, and the tail slender and keeled on each side; the mouth is crescentic, and the teeth are large, triangular, with sharp serrated edges; on each side five separate gill-openings appear in front of the large, falcate pectoral fins; the first dorsal fin is moderate, the second small and opposite the anal; the powerful caudal fin is lunate, the lower lobe being nearly as large as the upper, which is supported by the upturned end of the tail. This shark feeds on fishes and other marine animals; a young sea-lion, weighing 100 lb., was found in the stomach of one 30 ft. long. Teeth found fossil in tertiary strata, and others dredged in the Pacific ocean indicate the former existence of a *Carcharodon* about 90 ft. long. The porbeagles (*Lamna*) are similar in form to the great white shark, but have narrower piercing teeth. The thresher (*Alopias*) is more slender, and is remarkable for the great length of the upper lobe of the tail-fin; it swims near the surface and feeds on fishes, and has been observed to strike them with blows from the tail. The family Lamnidae also includes the basking shark (*Cetorhinus maximus*), which takes its name from its habit of basking at the surface. It is distinguished by the large mouth, minute conical teeth and very wide gill-clefts, the inner openings of which are guarded by series of long, slender gill-rakers. It reaches a length of 40 ft., but is quite harmless, feeding on minute organisms. Formerly it was hunted by harpooning off Ireland, for the sake of the oil from the liver.

The numerous species of the Carchariidae are mainly tropical, pelagic and piscivorous sharks, with sharp triangular teeth, distinguished from the Lamnidae by having the last one or two gill-openings above the pectoral fin. The tiger shark (*Galeocerdo tigrinus*) is one of the largest and most dangerous. The hammer-heads (*Sphyrna*) are peculiar in having the front part of the head produced outwards on each side, with the eyes at the ends of these extensions. The topes (*Galeus*) and hounds (*Mustelus*) are small bottom-living Carchariids with small teeth, which are serrated in the topes, blunt and forming a pavement in the hounds; both genera are represented in British seas.

The Scyliorhinidae include the dog-fishes, most of which are small bottom-living fishes, spotted, marbled or banded, with rounded fins and with small cuspidate teeth; they are distinguished from the Lamnidae and Carchariidae in that they are not viviparous, but lay large heavily-yolked eggs enclosed in oblong horny cases, with threads at each corner that serve for attachment. The Orectolobidae are distinguished by a pair of grooves running through the upper lip and connecting the nasal sacs with the mouth. *Orectolobus* of Australia and Japan includes species with a broad, flat head, margined with skinny flaps, much as in the angler (*Lophius*); most of the other species are bottom-living and have the appearance of dog-fishes, but one is pelagic and is the largest of all sharks, for it is said to reach a length of 70 feet. This shark (*Rhinodon*) known as the whale-shark, or at the Seychelles as the "chagrin," has the same numerous small teeth and long gill-rakers as the basking shark, which it resembles in habits.

A small group of sharks is distinguished by having six or seven gill-openings on each side, and a single dorsal fin, opposed to the anal. The six-gilled shark (*Hexanchus griseus*) is said to attain a length of over 25 ft.; there are a few records from British seas. The frilled shark (*Chlamydoselachus anguineus*) is an eel-shaped shark known from deep water off Japan and in the North Atlantic.

The third group of sharks has five gill-openings (six in *Pliotrema*), and two dorsal fins, each of which is typically preceded by a spine; most of these are bottom-living forms. The genus *Heterodontus* includes about seven species from the Indian and Pacific oceans, distinguished by having small teeth in the front of the jaws and large blunt teeth, suitable for crushing shell-fish, at the sides; the egg-case is conical, with spiral ridges. *H. philippi* is the Port Jackson shark. The piked dog-fishes (*Squalus*) inhabit the north and south temperate zones; they have no anal fin; the points of the small teeth are deflected laterally, so that the inner margin forms a cutting edge. *Squalus acanthias* is very abundant in British waters, and off the Atlantic coast of North America; it reaches a length of 4 ft.; it is a great nuisance to fishermen, eating fish caught in lines or in nets. All the Squalidae are viviparous; two noteworthy species of this family, both without fin-spines, are the spiny shark (*Echinorhinus*), a large bulky shark with spiny tubercles on the skin, and the Greenland shark (*Somniosus*) of the Arctic seas, which reaches a length of 25 ft., has conical teeth in the upper jaw and cutting teeth in the lower, and is active and voracious, often attacking whales. Many Squalidae (*Centrina, Centrophorus*, etc.) are inhabitants of deep water, and off Portugal are caught by long lines at depths of 400 or 500 fathoms. Closely related to the Squalidae are the saw-sharks, *Pristiophorus* of the Indo-Pacific and *Pliotrema* of South Africa, with the snout produced into a flat blade bearing a series of teeth on each side. Also related to the Squalidae are the angel-fishes or monks (*Squatina*) with flattened body, large wing-like pectoral fins, and terminal mouth with conical teeth; about ten species of this genus are known, mainly from temperate seas.

Few sharks are valued as food, but the dried fins are used by the Chinese for the preparation of gelatine, and for culinary purposes. Shagreen, used for polishing wood, is the skin of those kinds that are covered with numerous close-set pointed denticles. In recent years extensive fisheries for sharks have developed, starting in Carolina, and spreading to Africa, Australia, etc. The skins are made into leather of high quality; the oil obtained from the liver is said to be excellent, and the rest of the shark is used in the preparation of products such as glue, meal, etc. (*See* SELACHIANS; RAY.) (C. T. R.)

SHARON, a city of Mercer county, Pennsylvania, U.S.A., on the Shenango river, 60 m. N.N.W. of Pittsburgh and 15 m. N.E. of Youngstown, O. It is served by the Erie and the Pennsylvania railways, and for freight also by the New York Central and the Pittsburgh and Lake Erie. Pop. (1920), 21,747 (19% foreign-born white); 1930 Federal census 25,908. Sharon, together with the borough of Farrell (*q.v.*) adjoining it on the south, the borough of Sharpsville, 2 m. N.E. (pop. 4,674 in 1920), and other neighbouring communities, constitute an important unit of the Youngstown industrial district. The manufactures include iron, steel castings, automobile frames and accessories, steel hoops and barrels, tin plate, gas engines, oil tanks, tank cars, car wheels, steel rails, fire-brick, electrical transformers and many other articles. The aggregate product of the factories within the city limits in 1927 was valued at $27,564,501. Sharon was settled in 1795, but it remained small until coal-mining was begun in 1836. It was incorporated as a borough in 1841 and as a city in 1918.

SHARP, CECIL JAMES (1859–1924), British musician and writer, was born in London Nov. 22, 1859. He was educated at Uppingham and at Clare College, Cambridge, and, in 1883 went to South Australia where he founded a school of music at Adelaide. He was principal at the Hampstead Conservatoire, London, from 1896–1905, and director of the English Folk-Dance Society which he founded in 1911. His valuable work in collecting and arranging English folk-songs and dances, in lecturing on the subject revived interest in English national music. During a visit to America he discovered in the Appalachian Mountains interesting survivals of old national melodies. He died in London June 23, 1924.

Sharp's works include: *A Book of British Song* (1902); with C. L. Marson, *Folk Songs from Somerset*, series 1–5 (1904–19); *Folk Songs for use in Schools* sets 1–10; *English Folk Songs from the Southern Appalachians* (1917); *American English Folk Songs*, etc.; *English Folk Songs*, 2 vol. (1921); Posthum. with A. P. Oppé, *The Dance, an Historical Survey of Dancing in Europe* (1924). *See* Winifred A. S. Shaw, *Cecil Sharp, an Appreciation* (1925).

SHARP, GRANVILLE (1735–1813), English philanthropist, was born at Durham, the son of Thomas Sharp (1693–1758), a theological writer and the biographer of John Sharp, archbishop of York. Granville was apprenticed to a London draper, but in 1758 he entered the Government ordnance department. A diligent student of Greek and Hebrew, he published several treatises on biblical criticism, one of which, *Remarks on the Uses of the definitive article in the Greek Text of the New Testament*, gave rise to a controversy on account of the proposition, known as "Granville Sharp's canon," which it contained. His fame rests,

however, on his untiring efforts for the abolition of slavery. In 1767 he became involved in a law suit with a slave owner in which it was finally laid down that a slave becomes free the moment he sets foot on English territory. Sharp advocated the cause of the American colonies, supported parliamentary reform at home and the legislative independence of Ireland, and agitated against press gangs. In 1797 he founded a society for the abolition of slavery, and he was a joint founder of the British and Foreign Bible Society, and of the Society for the Conversion of Jews. Sharp died on July 6, 1813, and a memorial to him was erected in Westminster abbey.

See Prince Hoare, *Memoirs of Granville Sharp* (London, 1820), which contains observations by Bishop Burgess on Sharp's biblical criticisms; Sir James Stephen, *Essays in Ecclesiastical Biography* (London, 1860); Thomas Clarkson, *History of the Rise, Progress* and *Accomplishment of the Abolition of the African Slave Trade by the British Parliament* (London, 1839).

SHARP, JAMES (1618–1679), Scottish divine, the son of William Sharp, sheriff-clerk of Banffshire, was born in Banff Castle on May 4, 1618. In 1633 he went to King's College, Aberdeen, where he graduated in 1637. On the outbreak of the Covenanting War he visited Oxford, and perhaps Cambridge, becoming acquainted with the principal English divines. On his return he was chosen (1643) one of the "regents" of philosophy in St. Leonard's College, St. Andrews, and in 1648 was appointed minister of Crail in Fifeshire. In the great schism of Resolutioners and Protestors he took active part with the Resolutioners, and in March 1651 was taken prisoner by Cromwell, but subsequently liberated on parole. In 1657 he went to London to counteract the influence with the Protector of Archibald Johnston, Lord Warriston. He was again sent to London in Feb. 1660, to watch over the interests of the Resolutioners at the time of Monk's march to London. He was favourably received by Monk, who sent him to the king at Breda. He certainly regarded himself equally as the emissary of the Scottish kirk; he was also the bearer of a secret letter from Lauderdale to the king. There can be little doubt that he was finally corrupted by Charles and Clarendon, and decided that the interests of the Kirk should not imperil his own chances. He returned to Scotland in May 1660, and, while successfully stopping all petitions from Scottish ministers to the king, parliament or council, was at pains to allay the suspicions of his loyalty to the Kirk which had been aroused by his attitude in London. A letter of his (preserved in the Museum of the Society of Antiquaries, Edinburgh) dated May 21, 1661, from London, to Middleton the high commissioner, whose chaplain he now was, shows that he was in confidential communication with Clarendon and the English bishops; that he was cooperating in the restoration of Episcopacy in Scotland: that he was aware that Middleton, with whom he had held conferences, had all along intended it; and that he drew up the quibbling proclamation of June 10, whose sole purpose was "the disposing of minds to acquiesce in the king's pleasure." The mask at length dropped in August when Episcopacy was restored and Sharp was rewarded with the archbishopric of St. Andrews, Leighton, Fairfoul and Hamilton being consecrated bishops at the same time. On April 8 the new prelates entered Scotland, and on April 20 Sharp preached his first sermon at St. Andrews.

Sharp had kept on good terms with Lauderdale, and avoided acting against him on the occasion of the Billeting Plot concocted in Sept. 1662 by Middleton. When Lauderdale's supremacy was established he cooperated in passing the National Synod Act in 1663, the first step in the intended subjection of the church to the crown. In 1664 he obtained the grant of a new church commission. Gilbert Burnet made a written protest against the oppressive conduct of Sharp and other bishops, but Sharp failed to obtain a sentence of deprivation and excommunication against him. Sharp now placed himself in opposition to the influence of Lauderdale, in alliance with Rothes, Hamilton, Dalyell, and others but in 1665 he suffered, in London, a complete humiliation at the hands of Lauderdale, well described by Burnet. The result of their system of violence and extortion was the rising of the Covenanters, during which Sharp showed, according to Bellenden, the utmost fear, only equalled by his cruelty to the prisoners after the rout of Pentland. When the convention of estates met in January 1667 Hamilton was substituted for him as president, and he now wrote grovelling letters to Lauderdale, who extended him a careless reconciliation.

For a time he helped to restrain his brethren from complaining to London of Lauderdale's conciliation policy. On July 10, 1668, an abortive attempt to shoot him was made by James Mitchell in Edinburgh. After a visit to London Sharp assisted in December to carry out Tweeddale's tolerant proposals for filling the vacant parishes with some of the "ousted" ministers. In the debates on the Supremacy Act, by which Lauderdale destroyed the autonomy of the church, Sharp's reluctance gave way upon the first pressure, but he actively opposed Leighton's endeavour, as archbishop of Glasgow, to carry out a comprehensive scheme. From this time he was completely subservient to Lauderdale, who had now finally determined upon a career of oppression, and in 1674 he was again in London to support this policy. In this year Mitchell, who had shot at him six years before, was arrested, and Sharp obtained from him privately a full confession by a promise of pardon which he afterwards repudiated. It was, however, confirmed by the entry of the act in the records of the court. Mitchell was finally condemned, and Sharp refused to support the appeal for a reprieve. On May 3, 1679, while driving with his daughter Isabel to St. Andrews, he was set upon by nine men, and murdered in revenge. The place of the murder, on Magus Muir, now covered with fir trees, is marked by a monument erected by Dean Stanley, with a Latin inscription recording the deed.

Unless otherwise mentioned the proofs of the statements in this article will be found in vols. i. and ii. of the Lauderdale Papers (Camden Society) and in two articles in the Scottish Review (July 1884 and Jan. 1885).

SHARP, WILLIAM (1749–1824), English line-engraver, was born at London on Jan. 29, 1749. He was originally apprenticed to what is called a bright engraver, and practised as a writing engraver, but gradually became inspired by the higher branches of the engraver's art. He died at Chiswick on July 25, 1824. In his youth, owing to his hotly expressed adherence to the politics of Paine and Horne Tooke, he was examined by the privy council on a charge of treason. Mesmer and Brothers found in Sharp a staunch believer; and for long he maintained Joanna Southcott at his own expense. As an engraver he achieved a European reputation, and enjoyed many foreign honours. Among his earlier plates are some illustrations, after Stothard, for the *Novelists' Magazine*. He also engraved the "Doctors Disputing on the Immaculateness of the Virgin" and the "Ecce Homo" of Guido Reni, the "St. Cecilia" of Domenichino, the "Virgin and Child" of Dolci and the portrait of John Hunter of Sir Joshua Reynolds.

SHARP, WILLIAM (1856–1905), Scottish poet and man of letters, was born at Paisley on Sept. 12, 1856. His was a double personality, for during his lifetime he was known solely by a series of poetical and critical works of great, but not of outstanding merit, while from 1894 onwards he published, with elaborate precautions of secrecy, under the name of "Fiona Macleod," a series of stories and sketches in poetical prose which made him perhaps the most conspicuous Scottish writer of the modern Gaelic renaissance. His early life was spent chiefly in the W. highlands of Scotland, and after leaving Glasgow University he went to Australia in 1877 in search of health. After a cruise in the Pacific he settled for some time in London as clerk to a bank, became an intimate of the Rossettis, and began to contribute to the *Pall Mall Gazette* and other journals. In 1885 he became art critic to the *Glasgow Herald*. He spent much time abroad, in France and Italy, and travelled extensively in America and Africa. In 1885 he married his cousin, Elizabeth Amelia Sharp, who helped him in much of his literary work and collaborated with him in compiling the *Lyra Celtica* (1896). His volumes of verse were *The Human Inheritance* (1882), *Earth's Voices* (1884), *Romantic Ballads and Poems of Fantasy* (1886), *Sospiri di Roma* (1891), *Flower o' the Vine* (1894), *Sospiri d' Italia* (1906). William Sharp was the general editor of the "Canterbury Poets" series. He was a discriminating anthologist, and his *Sonnets of the Cen-*

tury (1886), to which he prefixed a useful treatise on the sonnet, ran through many editions. This was followed by *American Sonnets* (1889).

Sharp wrote biographies of Dante Gabriel Rossetti (1882), of Shelley (1887), of Heinrich Heine (1888), of Robert Browning (1890), and edited the memoirs of Joseph Severn (1892). The most notable of his novels was *Silence Farm* (1899). During the later years of his life he was obliged for reasons of health to spend all his winters abroad. The secret of his authorship of the "Fiona Macleod" books was faithfully kept until his death, which took place at the Castello di Manlace, Sicily, on Dec. 12, 1905. As late as the 13th of May 1899 Fiona Macleod had written to the *Athenaeum* stating that she wrote only under that name and it was her own. She began to publish her tales and sketches of the primitive Celtic world in 1894 with *Pharais: A Romance of the Isles*. They found only a limited public, though an enthusiastic one. The earlier volumes include *The Mountain Lovers* (1895), *The Sin-Eater* (1895), *The Washer of the Ford and other Legendary Moralities* (1896), etc. In 1897 a collected edition of the shorter stories, with some new ones, was issued as *Spiritual Tales, Barbaric Tales and Tragic Romances*. Later volumes are *The Dominion of Dreams* (1899); *The Divine Adventure: Iona: and other Studies in Spiritual History* (1900), and *Winged Destiny* (1904).

See a memoir by his wife (1910).

SHARP, in music, the sign ♯, signifying the raising of the note to which it is attached by a semitone, the direction holding good to the end of the bar. Or, if placed at the beginning of the stave, as part of what is called the key signature, it governs the note in question throughout the composition unless contradicted. A double sharp (𝄪) raises a note two semitones. (*See* ACCIDENTALS; CLEF: MUSICAL NOTATION.)

SHARPSBURG, a borough of Allegheny county, Pennsylvania, U.S.A., on the Allegheny river, opposite the north-eastern part of Pittsburgh; served by the Pennsylvania railroad. Pop. (1920) 8,921; and it was 8,642 in 1930. It is a manufacturing suburb, with iron and steel works, and factories making varnish, lubricating oil, oil-cans, glass and various other articles. There are coal mines and oil wells in the environs. Sharpsburg was settled in 1826 and incorporated as a borough in 1841. It was named after the original proprietor of the land, James Sharp.

SHARQAT, BATTLE OF, 1918. This is the name given to the final battle, Oct. 1918, in which the British in Mesopotamia, under General Marshall, overthrew the Turkish force which was covering Mosul, the last important centre then remaining in the hands of the Turks. (*See* MESOPOTAMIA, OPERATIONS IN.)

SHASI, a city in the province of Hupeh, central China, in latitude 30° 26′ N. and longitude 112° 5′ E., with an estimated Chinese population of 190,500. It is situated on the left bank of the Yangtze about 120 miles directly west of Hankow, though much farther distant by the river-route. It is admirably placed as an entrepôt centre in the low-lying cotton region of Hupeh amid a network of canals, one of which gives it direct connection with Hankow. These canal facilities have done much to restrict the development of Shasi as a river-port. Before the opening of Ichang (higher up the river) as a treaty port in 1895, Shasi was the usual transhipment centre for the Szechwan trade, but it subsequently lost much of its trade to Ichang. Shasi was opened to foreign trade by the treaty of Shimonoseki (1896) but only within the last 10 years has its total trade made really appreciable advances, due to a steadily growing export trade, chiefly in raw cotton. The annual increase was maintained in 1926, despite civil war in Hupeh and Hunan.

		s d Haikwan Taels 3/8
1926	Net Foreign imports	3,044,700
	Net Chinese imports	5,614,281
	Exports	24,133,311
	Total	32,792,292

The value of the total trade was in 1904, Hk. Taels 1,956,371; 1911, 2,948,656; 1924, 23,594,654. Shasi is a distributing centre for salt, fibres and nutgalls, from Szechwan; the import of salt averaging about 400,000 bags, and nutgalls about 100,000 chests annually. The foreign import trade is chiefly in cotton piece goods, kerosene oil, and refined sugar. The basis of an active export trade is raw cotton, which was shipped to the amount of 650,000 piculs in 1926. Seeds, especially rape and cotton seeds, are also exported. In 1913 a contract was signed for the construction of a railway from Shasi, via the Yuan-kiang valley, south-westward to Kwei-yang, capital of Kweichow province. Work on this scheme was, however, held up by the World War. The construction of a railway westward from Hankow into Szechwan (via Shasi) is one of the railway projects most likely to materialize in the near future.

SHASTA. This Indian group, of Hokan speech stock, lived on and south of Klamath river, east of Mt. Shasta. Culturally they stood intermediate between the north-western tribes, such as the Yurok and Hupa (*q.v.*) and the Maidu (*q.v.*) and other central Californians. Originally numbering 2,000, they have dwindled to a few dozen scattered households.

See R. B. Dixon, *Bull. Am. Mus. Nat. History,* vol. xvii. (1907).

SHASTA, MOUNT, a peak at the northern extremity of the Sierra Nevada range in Siskiyou county, California, U.S.A. It is the cone of an extinct volcano rising to a height of 14,161 ft. above sea-level. Its deep-fluted sides show that it has been considerably lowered and wasted by ice action. The remaining glaciers, which extend down to within 9,500 ft. of sea-level, are but a remnant of their former greatness. A sulphurous fumarole just below the extreme summit and another on its north slope still show vestiges of volcanic activity.

See John Muir, *The Mountains of California* (9th ed., 1911) and *Spirit Leveling in California 1896–1923* (1925), which is Bulletin No. 766 of the United States Geological Survey.

SHATT-AL-ARAB, a river in Mesopotamia formed by the junction of the Tigris and the Euphrates (*qq.v.*). There is reason to believe that the stream is not of great antiquity. (*See* MESOPOTAMIA: *Ancient Geography.*) The Shatt-al-Arab may be said to extend from Qurna to the bar at Fao, and the effect of the tide reaches up to the former point, where formerly the Euphrates discharged. It is 123 miles long. The importance of the Shatt-al-Arab is restricted to its lower reach from Basra to Fao, the railway from Baghdad having its terminus at Basra. Between Basra and Mohammera, the Persian port at the junction of the Karun with the Shatt-al-Arab, the river has an average breadth of 600 yards. At the actual point of junction the river widens out to half a mile and at Fao, 49 m. down stream, it is a mile broad. Below Fao the river rapidly widens and flows through interminable sandbanks and mudflats to the Persian Gulf.

The utility of the river for navigation is restricted by the bar at Fao, which allows only vessels of under 11 ft. draught to pass at low water. Sir Arnold Wilson has computed that the silt coming down the river annually is about half a million tons; the amount deposited in the main channel would be insignificant if, after dredging, a channel of 24 ft. at low water were maintained. Beyond the bar there is a depth of 30–40 ft. except in two places, the bar at Mohammera at the confluence of the Karun being the only other serious restriction to navigation.

Rawlinson suggests that there are three main facts to be considered in the history of the Shatt-al-Arab. First the coast line at the mouth of the Shatt-al-Arab advanced very slowly until, at the end of the 18th century, the Karun forced its way into the Shatt-al-Arab. When this happened the Shatt-al-Arab began to enlarge its bed and began to cut the great bend between Mohammera and Abadan. After this islands began to form at the mouth of the Shatt-al-Arab. (*See* also MESOPOTAMIA, and BASRA.)

Wilson, "The Delta of the Shat-al-Arab and Proposals for Dredging the Bar," *Geographical Journal,* lxv., p. 225 (1925); Colonial Office annual *Reports.*

SHAUGHNESSY, THOMAS GEORGE SHAUGHNESSY, 1ST BARON, cr. 1916 (1853–1923), Canadian railway magnate, was born at Milwaukee Oct. 6, 1853. He began railway service at the age of 16, and in 1882 joined the staff of the

Canadian Pacific Railway as general purchasing agent. In 1891 he was appointed a vice-president and from 1899 to 1918 he was president and chairman of the board of directors, and director of all the allied lines. He died in Montreal on Dec. 10, 1923.

SHAW, ANNA HOWARD (1847–1919), American reformer, was born at Newcastle-upon-Tyne on Feb. 14, 1847. When she was a small child, her parents moved to the United States. From 1872 to 1875 she studied at Albion college (Mich.), and in 1878 graduated from the theological school of Boston university. The district conference of the Methodist Episcopal Church granted her a local preacher's licence, but the New England Conference of the M.E. Church refused to ordain her because of her sex, and the refusal was upheld by the General Conference at Cincinnati in 1880. The same year she was ordained in the Methodist Protestant Church. While preaching she had studied medicine and received the degree of M.D. from Boston university in 1885.

She was associated after 1886 with the National American Woman Suffrage Association in various capacities, from 1904–15 as president. In 1917 she was chairman of the woman's committee of the Council of National Defence. She died at Moylan (Pa.), on July 2, 1919

SHAW, GEORGE BERNARD (1856–), Irish dramatist, was born in Dublin on July 26, 1856. His father, George Carr Shaw, a younger son of Bernard Shaw, high sheriff of Kilkenny, was an impoverished and humorously helpless member of what, in England, would have been called the middle class, but in Ireland is still called the gentry. He was first employed by the Government in the Four Courts, then the Dublin Law Courts, and when his office was abolished in 1850 compounded his pension for a lump sum, with which he became a member of the Dublin Corn Exchange, engaging in a business of which he was totally ignorant, that of a corn merchant. He married Lucinda Elizabeth Gurly, who was the daughter of Walter Bagenal Gurly, a landed proprietor in County Carlow. Three children were born of the marriage, Lucinda Frances, Elinor Agnes and George Bernard.

The financial affairs of the Shaw family did not prosper, but the young wife, who had a *mezzo soprano* voice of remarkable purity, became known as an amateur singer. There was then in Dublin a gifted conductor and teacher of singing, named George John Vandaleur Lee, with whose work Mrs. Shaw became associated. In this way the Shaw children, despite their father's financial straits, acquired a considerable musical culture which was extended to the theatre by her amateur operatic performances. Her son, after a private grounding in Latin grammar from his uncle, the Rev. William George Carroll, vicar of St. Bride's, Dublin, who was reputed to be the first minister of the Church of Ireland to proclaim himself a Home Ruler, was like many other Church of Ireland children, sent to the Wesleyan Connexional School, later known as Wesley college, in Dublin, and was "generally near or at the bottom of his classes." At home, however, he acquired an extensive acquaintance with the works of composers of music, so that before he was 15, "he knew at least one important work by Handel, Mozart, Beethoven, Mendelssohn, Rossini, Bellini, Donizetti, Verdi and Gounod from cover to cover." He studied pictures in the National Gallery of Ireland, and at 15 "knew enough of a considerable number of painters to recognize their work at sight."

In 1871, when he was 15 and had no hope of going to a university, he received, through the influence of his uncle, Frederick Shaw, an appointment in the office of a Dublin land agent, Charles Uniacke Townshend, at a commencing salary of £18 per annum. At the end of a year, when he was 16, the important post of cashier unexpectedly became vacant, and he was temporarily appointed to it. He filled it so ably that he was confirmed in it, and his salary, then £24 per annum, was doubled. In 1876, no longer able to endure employment which had always irked him, he withdrew from it and joined his mother, who, some years earlier, had settled in London and become a professional teacher of music. But before he did this he made his first communication to the Press. The American evangelists Moody and Sankey had arrived in Dublin to conduct a revival, and he went to hear them deliver their gospel. After he had heard it he wrote a letter, signed "S," and dated April 3, 1875, to *Public Opinion,* in which he asserted, to the horror of his pietistic relatives, that if this sort of thing was religion then he, on the whole, was an atheist.

The first nine years of his life in London were passed in poverty and oppressed to some extent by a sense of failure. His literary earnings in that time amounted to six pounds. "When people reproach me," he wrote in 1896, "with the unfashionableness of my attire, they forget that to me it seems like the raiment of Solomon in all his glory by contrast with the indescribable seediness of those days when I trimmed my cuffs to the quick with scissors, and wore a tall hat and *soi-disant* black coat green with decay." In those nine years, 1876–85, he "devilled" for a musical critic; began a passion play in blank verse which he did not finish; wrote an article for *One and All,* of which George R. Sims was editor, the payment for which was 15s., wrote an article on patent medicines for £5, and a verse for a school prizebook for 5s., and composed five novels. He was supported during these nine years by his mother, and by his father, who was still struggling with his dwindling business on the Dublin Corn Exchange. On a few occasions he endeavoured "to earn an honest living," the last occasion being in 1879, when, for a few months, he was in the service of a company formed in London "to exploit an ingenious invention by Mr. Thomas Alva Edison." Thereafter he insisted on following the bent of his mind. "I did not throw myself into the struggle for life: I threw my mother into it. I was not a staff to my father's old age: I hung on to my father's coat tails. . . . Callous as Comus to moral babble, I steadily wrote my five pages a day and made a man of myself (at my mother's expense) instead of a slave." Such glimpses of London society as he obtained he owed to the possession of a suit of evening clothes and to his being a sufficiently sympathetic accompanist to be tolerated as an amateur in musical circles.

Between 1879 and 1883 the five novels were written—one each year. The first was, "with merciless fitness," called *Immaturity.* It was declined by all the publishers, including Chapman and Hall, whose reader, George Meredith, wrote "No" on it. The manuscript was thrown aside and nibbled by mice, but "even the mice failed to finish it." *The Irrational Knot, Love Among the Artists, Cashel Byron's Profession* and *An Unsocial Socialist* proved equally unacceptable, and it was not until after he had made many friends in advanced political and humanitarian circles that they were printed as padding in propagandist magazines.

In 1882, when Bernard Shaw was 26 and the author of four unpublished books, he attended a public meeting at the Memorial Hall, Farringdon street, London, which was addressed by Henry George on the subject of land nationalization. George believed that the social ills of mankind would be cured by the nationalization of land, or single tax; all other forms of capital could safely be left in private possession. Shaw resolved to join in George's campaign, but he did not long remain in it, for, on proceeding from a study of George's *Progress and Poverty* to Marx's *Capital* he became a Socialist and demanded the nationalization of *all* forms of capital, a demand which was repugnant to George. In this campaign Shaw made a number of firm friendships—with James Leigh Joynes, Sydney Olivier (later Lord Olivier), Henry Hyde Champion, the Rev. Stewart D. Headlam, Henry S. Salt and his wife, William Morris, Annie Besant, Edward Carpenter and Sidney and Beatrice Webb.

Propaganda magazines inevitably followed in the trail of these friends, and in one of them, printed by Champion and called *To-day, An Unsocial Socialist* and *Cashel Byron's Profession* were serialised. *To-day* died, and was succeeded by *Our Corner,* published by Mrs. Besant, with whom Shaw had become acquainted about the time that he joined the Fabian Society, a society of Socialists founded in 1884. *The Irrational Knot* and *Love Among the Artists* were serialised in this magazine. It, too, died. *Cashel Byron's Profession* had an artistic, but not a popular success. Stevenson was enraptured by it, and Henley wanted to make a play out of it. Shaw himself, some years afterwards, burlesqued it for the stage under the name of *The Admirable Bashville,* in excellent blank verse.

It was abundantly clear in these novels, written after the style of the 18th century authors, that narrative was *not* the form in which Shaw could best express himself. He ran to dialogue rather than to description or to narrative, and his characters on any or no provocation uttered long speeches that read like platform deliveries rather than conversation. The *story* was always a poor one when there was any story at all; the author was not fastidious about the peg on which he hung his opinions. He shared with Shakespeare a willingness to use any plot that would serve his purpose. But he could not continue to use a form which was intractable in his hands, and so, after many diversions and adventures in search of a suitable instrument, he turned to the stage. It may here be said, however, that the novels were a preparation for the plays. Much of what is in the former, was re-used in the latter. The hatred of hypocrisy and pretentious respectability and irrational social cleavages and stupefying poverty and every kind of organised priestcraft, whether of the law or the church or of medicine or of politics, which he acquired in Dublin as a boy and a youth, was poured into his novels and distilled from them into his plays. Ann Whitefield, who takes the initiative in the sex duel with John Tanner in *Man and Superman,* is descended from Madge Brailsford who hunts down Owen Jack in *Love Among the Artists.* The conclusion of *Love Among the Artists,* as Julius Bab has pointed out, is almost identical in situation and words with the conclusion of *Candida.*

His fortunes now began to mend. He criticised books for the *Pall Mall Gazette* and pictures for *The World.* He was appointed musical critic of the *Star,* under the pseudonym of "Corno di Bassetto," but he presently transferred himself in the same capacity to *The World,* in which he made his initials G.B.S. familiar to the public. Later on he acted as dramatic critic of *The Saturday Review.* During this period of critical activity, however, he was arduously engaged in his political propaganda. Henry George's *Progress and Poverty* diverted his attention from the so-called controversies between science and religion to political economy, to which he devoted several years of study; Karl Marx's *Das Kapital,* which he read in French, completed his disillusion with capitalistic civilisation. He took up public speaking and incessantly addressed "audiences of every description, from university dons to London washerwomen. From 1883 to 1895, with virtually no exception, he delivered a harangue with debate, questions, and so on every Sunday—sometimes twice or even thrice—and on a good many weekdays. This teeming and tumultuous life was passed on many platforms, from the British Association to the triangle at the corner of Salmon's lane in Limehouse." He was now a most active member of the Fabian Society, which he joined in 1884, and was the author of its second and third tracts.

In 1898 Shaw's health yielded under the weight of his work. He recovered after his marriage in that year to Charlotte Payne-Townshead, but did not resume his former incessant activity on the platform. He became, instead, a co-opted member of the Vestry of St. Pancras, now the St. Pancras Borough Council. To his six years' work on that body we owe his *Common Sense of Municipal Trading.* He contested the County Council seat; but the result confirmed his conviction that the Conservatives would vote against him and none of the Liberals for him. This was his only open candidature for popular election. His chief political work was done in the committees of the Fabian Society. By this time he was well known as a brilliant and witty critic and debater, but was hardly known at all as an author, although, in addition to his novels, he had written *The Sanity of Art* (1908), a reply to Dr. Max Nordau's *Degeneration; The Perfect Wagnerite* (1898); *The Quintessence of Ibsenism* (1891); and four plays.

But from 1894 his rise to world fame was steady and swift. He now definitely was a dramatist, publishing his plays for general reading (then an innovation in London) with elaborate prefaces on political, social and finally on religious and biological questions, which were quite independent of the plays to which they were attached. Thus he became known as an unacted dramatist before he was conclusively accepted on the London stage after 1904. His vogue as an acted dramatist began in New York and Germany about six years earlier.

The first of these plays was finished in 1892, seven years after it had been begun in collaboration with William Archer. Shaw, it seemed, could write "incomparable" dialogue, but "construction was not his strong point"; Archer "could not write dialogue a bit, but . . . considered himself a born constructor." They agreed to pool their abilities and make a play. Archer constructed "a twaddling cup-and-saucer comedy . . . to be called *Rhinegold.*" But Shaw held that plot was the curse of fiction, literary or dramatic; and Archer was the apostle of plot and construction. Consequently the plot, in Shaw's hands, underwent such a change that Archer retired from the collaboration, nor did he ever expect to see the play completed. Seven years later, to help the Independent theatre out of an emergency, Shaw finished the play —a treatise on slum-property—and it was performed for the first time under the management of Mr. J. T. Grein at the Royalty theatre in London in Dec. 1892. Shaw was then in his thirty-seventh year. Archer, writing in *The World,* earnestly endeavoured to dissuade Shaw from following a career as a dramatist, "for which he has no special ability, and some constitutional disabilities." In 1893 he wrote *The Philanderer,* a topical comedy on Ibsenism and the "new woman," for the same theatre, but the piece proved technically unsuitable for Mr. Grein's company. To replace it Mr. Shaw wrote *Mrs. Warren's Profession,* which was refused a license by the Lord Chamberlain and was not presented until Jan. 5, 1902, when it was privately given by the Stage Society at the New Lyric theatre. When it was played in New York by the late Arnold Daly's company in 1905 the actors were prosecuted. These three plays were classed by the author as "unpleasant plays" in the printed version. *Arms and the Man* was produced at the Avenue theatre (April 21, 1894) by Miss Florence Farr, who was experimenting on the lines of the Independent theatre, and by Mr. Richard Mansfield at the Herald Square theatre, New York (Sept. 17, 1894). The scene was laid in Bulgaria, the piece being a satire on romanticism, a destructive criticism on military "glory." *Candida* was written in 1894 and won a decisive success in Germany with Agnes Sorma as Candida; but the London managers would have none of it. It won Shaw many friends as a vindication of the woman in the home.

He had found no regular English audience when he published *Plays Pleasant and Unpleasant* (2 vols.), in 1898, and his pieces first became well known to the ordinary playgoer by the performances given at the Royal Court theatre under the management of T. E. Vedrenne and Harley Granville-Barker. *Man and Superman* (published in 1903) was produced there on May 23, 1905, in a necessarily abridged form, with Granville-Barker in the part of John Tanner, the author of the "Revolutionist's Handbook and Pocket Companion," printed as an appendix to the play. A great success was *John Bull's Other Island,* dealing satirically with Ireland, as she was before receiving autonomy. *Major Barbara* (Court theatre, Nov. 1905), announced as a "discussion in three acts," placed the Salvation Army on the stage. The last of the plays, *Saint Joan,* was written in 1923. It will be seen, then, that the bulk of Shaw's dramatic work was done after he had passed his 40th birthday, and that half of it was done after he had reached the age at which Shakespeare died. It will also be seen that the three plays which are now considered to be his greatest, *Heartbreak House, Back to Methuselah* and *Saint Joan,* were written when he was well over 60 years of age. Three of the plays, *Mrs. Warren's Profession, The Shewing-up of Blanco Posnet,* and *Press Cuttings* were banned by the censor, but the ban was subsequently lifted from them. *Passion, Poison and Petrifaction* is a burlesque melodrama written for the benefit of the Actors' Orphanage. *The Interlude at the Playhouse* is a topical prologue quoted at length in the *Daily Mail,* Jan. 29, 1907, and not otherwise published. His political writings, in addition to a number of Fabian tracts and pamphlets, include *Common Sense about the War, Peace Conference Proposals,* and *The Intelligent Woman's Guide to Socialism and Capitalism.*

The plays vary from exposure of social wrongs, as for example slum ownership in *Widowers' Houses* and prostitution in *Mrs. Warren's Profession,* to philosophical and religious disquisitions, as in *Misalliance* and *Androcles and the Lion, Heartbreak House,*

metabiological prophecies, as in *Back to Methuselah,* and dramatised historical chronicle, as in *Caesar and Cleopatra* and *Saint Joan.* Shaw has ranged through a great variety of scenes in his plays—America, Bulgaria, Egypt, England, France, Germany and Ireland, and he is always careful to make the settings as picturesque and romantic as possible. He goes to extraordinary lengths to introduce oddity into his work, as when he makes Captain Shotover, in *Heartbreak House,* live in a house shaped like a ship, and causes one of the characters in the play to wear the clothes of an Arab chief in the evening. At first, his work seemed to express an absolute determinism—not man, but his environment, was at fault—but in his later plays he insists, in Macbeth's phrase, that man "still has judgment here," and expresses what may be called a neo-Protestant belief. Mankind, in *Back to Methuselah,* reaches through creative evolution a state of longevity which resembles eternal life. Joan of Arc protests that no one shall stand between God and her.

The general religious belief expressed in the plays may be briefly summarised as follows: God, or the Life Force, is an imperfect power striving to become perfect. If He were omniscient and omnipotent, He would not allow certain horrors to exist in the lives of His creatures, any more than an ordinary father would tolerate disease in his children if he could prevent it. The whole of time has been occupied by God in experiments with instruments invented to help Him in His attempt to perfect Himself. When He found that these instruments were either useless or no longer serviceable He scrapped them. In this way the disappearance from the world of mammoth beasts, among other creatures, is explained. God eventually found that all His instruments suffered from a common defect, that they were incapable of apprehending His purpose and unable to help overcome their circumstances and bodily limitation. He thereupon created a new instrument, Man, who is still on probation. Shaw warns the world that if we, too, fail to achieve God's purpose He will become impatient and scrap mankind as He scrapped the mammoth beasts. "You should live so that when you die God is in your debt." He was awarded the Nobel Prize for literature in 1926, but immediately handed over the money, amounting to more than £7,000, to the Anglo-Swedish Foundation for spreading a knowledge of Swedish literature in English-speaking countries.

SHAW, HENRY WHEELER (1818–1885), American humorist, known by the pen-name of "Josh Billings," was born of Puritan stock at Lanesborough (Mass.), April 21, 1818. He left Hamilton college to go West, where he worked on steamboats, farmed, and was an auctioneer. In 1858 he settled in Poughkeepsie (N.Y.), as a land agent and auctioneer, and began writing, especially for the *Poughkeepsie Daily Press.*

His "Essa on the Muel bi Josh Billings" (1860) in a New York paper won him an audience he could not secure by more conventionally spelled articles and was followed by many similar contributions, chiefly in the *New York Weekly* and the *New York Saturday Press,* and by several popular volumes, among which are *Josh Billings: His Sayings* (1866); *Josh Billings on Ice and Other Things* (1868); *Josh Billings: His Works, Complete* (1876); *Trump Kards* (1877); *Old Probabilities* (1879); *Josh Billings' Spice-Box* (1881), and his burlesques of the familiar almanacs, issued annually for the decade beginning 1870, and collected into a volume in 1902 under the title *Josh Billings' Old Farmers' Allminax.* He died in Monterey (Calif.), Oct. 14, 1885. He was his best in the humorous aphorism and displayed a shrewd philosophy, especially in his contributions to the *Century Magazine* under the name of Uncle Esek.

See *Life and Adventures of Josh Billings* (1883), by F. S. Smith.

SHAW, JOHN BYAM (1872–1919), English painter, was born at Madras on Nov. 13, 1872. He came to England in 1878 and after studying at the St. John's Wood school of art, entered the Royal Academy schools in 1889. His picture, "Rose Mary," was hung in 1893. One of his best known works was "Love the Conqueror" (1899). He illustrated many books, including Browning's *Poems* (1898); *Tales from Boccaccio* (1899); *Pilgrim's Progress* (1904); Edgar Allan Poe's *Tales* (1909), etc. In 1911 he established with Rex Vicat Cole (b. 1870), a school of art at Kensington. He died in London on Jan. 26, 1919.

SHAW, LEMUEL (1781–1861), American jurist, was born at Barnstable, Mass., Jan. 9, 1781. He graduated at Harvard college in 1800, and was admitted to the bar in 1804. In 1805 he began to practise law in Boston. He was a prominent Federalist and was a member of the Massachusetts house of representatives in 1811–14, in 1820 and in 1829, and of the State senate in 1821–22, a delegate to the State constitutional convention of 1820–21, and chief justice of the supreme court of the State from 1830 to 1860. He presided over the trial in 1850 of Prof. John White Webster (1793–1850) for the murder of Dr. George Parkman. His opinion in *Cary* v. *Daniels* (8 Metcalf) is the basis of the present law in Massachusetts as to the regulation of water power rights of riparian proprietors. He died in Boston, March 30, 1861.

See the address by B. F. Thomas in *Proceedings of the Massachusetts Historical Society,* x. 50–79 (Boston, 1869).

SHAW, RICHARD NORMAN (1831–1912), British architect, was born in Edinburgh on May 7, 1831. At the age of sixteen he was apprenticed in London to William Burn. He also attended the architectural schools of the Royal Academy, where, in 1854, he gained the gold medal and two years' travelling studentship. On his return in 1856 he published the drawings made during his two years abroad, *Architectural Sketches from the Continent.* He then entered the office of G. E. Street, and presently became his chief assistant. In 1863, after sixteen years of severe training, he began to practise. He went into partnership with W. E. Nesfield, who had worked with him in Burn's office, and even when the partnership was dissolved the two men occupied the same office for some time. In 1872 Shaw was elected an Associate of the Royal Academy, and a full member in 1877; he joined the "retired" list towards the end of 1901. He died at Hampstead on Nov. 7, 1912.

Characteristic examples of Shaw's work are Preen Manor, Shropshire; New Zealand Chambers, Leadenhall Street; Pierrepont, Wispers, and Merrist Wood, in Surrey; Lowther Lodge, Kensington; Adcote, in Shropshire; his houses at Kensington, Chelsea and at Hampstead; Flete House, Devonshire; Greenham Lodge, Berkshire; Dawpool, in Cheshire; Bryanstone, in Dorsetshire; Chesters, Northumberland; New Scotland Yard, on the Thames Embankment; besides several fine works in Liverpool and the neighbourhood. Shaw broke away from the academic tradition in which he was held, to adopt the characteristic style which entirely changed English domestic architecture. Shaw's style has been vulgarized by the imitations of the speculative builder, but the houses he himself designed were admirable in proportion and in their adaptation to their purpose. They were the outcome of much enthusiastic and intelligent study of old examples, and were based directly on old methods and traditions. As his powers developed, his buildings gained in dignity, and had an air of serenity and a quiet homely charm which were less conspicuous in his earlier works; the "half timber" was more sparingly used, and finally disappeared entirely. His planning is invariably fine and full of ingenuity. Adcote (a beautiful drawing of which hangs in the Diploma Gallery at Burlington House) is perhaps the best example of the series of his country houses built between 1870 and 1880. The elements are few but perfectly proportioned and combined, and the scale throughout is consistent. The Great Hall is the keynote of the plan, and is properly but not unduly emphasized. New Scotland Yard is undoubtedly Mr. Shaw's finest and most complete work. Unfortunately no great public rebuilding scheme in London was ever entrusted to him, but his spirit and his enthusiasm for his art inspired many of the younger men.

SHAWINIGAN FALLS, a pulp, paper and power centre in St. Maurice county, Quebec, Canada, on the St. Maurice river, 21 m. N. of Three Rivers, and on the Canadian National and Canadian Pacific railways. It is the site of the Shawinigan

Water and Power Company, which carries the highest voltage line in operation in Canada. It is also a centre for the pulp and paper industry in Canada, an industry which has grown since 1900 from a gross value of production of less than $10,000,000 to more than $250,000,000. Shawinigan Falls itself contains manufactures with the gross value of $16,381,429. Pop. (1931), 15,345.

SHAWL. A square or oblong article of dress worn in various ways dependent from the shoulders. The term is of Persian origin (*shâl*), and the article itself is most characteristic of the natives of north-west India and central Asia; but in various forms, and under different names, the same piece of clothing is found in most parts of the world. The shawls made in Kashmir occupy a pre-eminent place among textile products; and it is to them and to their imitations from western looms that specific importance attaches. The Kashmir shawl is characterized by the elaboration of its design, in which the "cone" or "mango" pattern is a prominent feature, and by the glowing harmony, brilliance, depth and enduring qualities of its colours. The basis of these excellences is found in the very fine, soft, short, flossy under-wool, called pashm or pashmina, found on the shawl-goat, a variety of *Capra hircus* inhabiting the elevated regions of Tibet. There are several varieties of pashm, but the finest is a strict monopoly of the maharaja of Kashmir. Inferior pashm and Kirman wool—a fine soft Persian sheep's wool—are used for shawl weaving at Amritsar and other places in the Punjab, where colonies of Kashmiri weavers are established. Of shawls, apart from shape and pattern, there are only two principal classes: (1) loom-woven shawls called tiliwalla, tilikár or káni kár—sometimes woven in one piece, but more often in small segments which are sewn together with such precision that the sewing is quite imperceptible; and (2) embroidered shawls—amlikár—in which over a ground of plain pashmina is worked by needle a minute and elaborate pattern.

SHAWM or **SHALM,** the mediaeval forerunner of the wooden double-reed wind-instrument now called the oboe (*q.v.*).

SHAWNEE. This Algonkin tribe lived, when discovered in the 17th century, in two wholly separated portions, one on Cumberland river in Tennessee and Kentucky, the other on Savannah river in South Carolina. Like their relatives the Sauk, Fox and Kickapoo, they were restless and inclined to wander. Toward the end of the 17th century the eastern division moved north into Pennsylvania, and early in the 18th the other began to drift north-westward across the Ohio. The two divisions united, for the first time in the historic period, about 1750 in eastern Ohio. They fought the British or Americans until 1795, then variously joined the Cherokee or Creek or withdrew to Indiana and even Missouri. Those in Indiana were again defeated at Tippecanoe in 1811. Portions of the tribe lived for a time in Texas and Kansas, and they are now gathered in Oklahoma, though in several districts. They number 1,400.

SHAWNEE, a city of Pottawatomie county, Oklahoma, U.S.A., on the North Canadian river, 38 m. E.S.E. of Oklahoma City, at an altitude of 1,006 ft.; served by the Oklahoma City-Ada-Atoka, the Rock Island and the Santa Fe railways. Pop. (1920) 15,348; in 1930, 23,283. It is the trading centre and shipping point for a farming and stock-raising country; has cotton gins and compresses, cottonseed-oil mills, a large meat-packing plant, railway shops and other manufacturing industries, with an output in 1927 valued at $5,716,284; and is the seat of the Oklahoma Baptist University (1910). The site of Shawnee was in the territory of the Pottawatomie Nation. The city was founded in 1895 and incorporated in 1896.

SHAYS, DANIEL (1747–1825), American soldier, the leader of Shays's Rebellion, 1786–87 (*see* MASSACHUSETTS: *History*), was born in Hopkinton, Mass., in 1747. In the Revolutionary War he served as second lieutenant in a Massachusetts regiment from May to Dec. 1775, and became captain in the 5th Massachusetts Regiment in Jan. 1777. He took part in the battle of Bunker Hill, and in the expedition against Ticonderoga, participated in the storming of Stony Point and fought at Saratoga. In 1780 he resigned from the army. After the collapse of Shays's Rebellion he escaped to Vermont. He was pardoned in June 1788, and died at Sparta, N.Y., on Sept. 29, 1825.

See J. T. Adams, *New England in the Republic 1776–1850,* pp. 146–166 (Boston, 1926).

SHEARER, THOMAS, English 18th-century furniture designer and cabinet-maker. The solitary biographical fact known is that this distinguished craftsman was the author of most of the plates in *The Cabinet Maker's London Book of Prices and Designs of Cabinet Work,* issued in 1788 "For the London Society of Cabinet Makers." The majority of these plates, republished separately as *Designs for Household Furniture,* exhibit simplicity of design, delicacy of proportion and originality. There can be little doubt that Shearer exercised considerable influence over Hepplewhite. Shearer, in his turn, owes something to the brothers Adam. It is probable that he worked at his craft with his own hands and that he was literally a cabinet-maker—so far as we know, he never made chairs. Much of the elegance of Shearer's work is due to his graceful and reticent employment of inlays of satinwood and other foreign woods.

SHEARING MACHINES: *see* PUNCHING AND SHEARING MACHINES.

SHEARWATER, *Puffinus puffinus,* family *Procellariidae,* a sea bird with a wide distribution in the North Atlantic, though rarely resorting to land, except in the breeding season. The Manx shearwater is the only one that breeds in Britain. It is a plain-looking bird, black above and white beneath, and about the size of a pigeon. Its flight is graceful as it skims close over the waves. Shearwaters are widely distributed pelagic birds, spending the greater part of their lives on the ocean. The shearwater lays its single white egg in a hole underground. The young are thickly clothed with long down and are extremely fat. In this condition they are thought good eating, and enormous numbers are caught in some localities, especially of *P. brevicaudus,* which frequents islands off Australia, where it is known as the "Mutton bird."

SHEATHBILL (*Chionis alba*), a bird so-called from the horny case which ensheaths the basal part of its bill.

The Sheathbill is about the size of a pigeon; its plumage is pure white, its bill somewhat yellow at the base, passing into pale pink towards the tip. Round the eyes the skin is bare and beset with cream-coloured papillae, while the legs are bluish-grey. The second eastern species, *C. minor,* is smaller, with a dark bill and legs and a differently shaped "sheath." The western species gathers its food, consisting of sea-weeds and shell-fish, on rocks at low water; but it is also known to eat birds' eggs. Though most abundant as a shore-bird, it is frequently met with far out at sea. It is not uncommon on the Falkland Isles, where it breeds. *C. minor* inhabits Kerguelen Land, Prince Edward Island, Marion Island, and the Crozets. The eggs of both species are not unlike those of oyster-catchers. The sheathbills constitute the family *Chionidae* of the plovers (*Charadriiformes*).

SHEBOYGAN, a city of eastern Wisconsin, U.S.A., on Lake Michigan at the mouth of the Sheboygan river, 52 m. N. of Milwaukee; a port of entry and the county seat of Sheboygan county. It is on Federal highway 141, and is served by the Chicago and North-western and the Milwaukee Electric railways and lake steamers. Pop. 30,955 in 1920 (27% foreign-born white) and was 39,251 Federal census 1930. There is a good harbour, open throughout the year, which in 1928 had traffic amounting to 448,226 tons, valued at $7,532,100. The city ships 80,000,000 lb. of cheese in a year, and millions of gallons of its mineral waters. It has a large fishing industry, and its manufactures are varied and extensive. Chairs, enamel-ware, desks and bookcases are among the leading products. The aggregate factory output in 1927 was valued at $31,034,062. The city's assessed valuation of property for 1927 was $51,977,171. About 1820 a trading post was established at the mouth of the Sheboygan river, and in 1834 a saw-mill was built at the first rapids, 2 m. above. Settlers came in rapidly; a great city was laid out on paper; and the village was incorporated in 1846. It was chartered as a city in 1853, and in 1860 had a population of 4,262. The decade 1880–90 was a period of rapid growth. From 1845 to 1848 a Fourierist community of ten families (the Spring Valley Association) successfully farmed 30 ac. of land several miles S.W. of Sheboygan, dissolving by

mutual agreement because they lost interest in the experiment.

SHECHEM, an ancient town of Palestine, 6 m. S. of Samaria, mod. Nāblus. The modern town lies in the valley between Ebal and Gerizim in a beautiful situation: pop. in 1922, 15,947 (145 Samaritans and 700 Christians). The Samaritan quarter is in the south-west of the city and contains their synagogue. Nāblus is connected by rail with the Haifa-Damascus line at Afuleh, and with the Lydda-Haifa line at Tulkarem.

History.—The site was occupied in patriarchal times by Hivites (Gen. xxxiv., 2). There Jacob and his family settled for a time (Gen. xxxiii., 18). It was set apart as a city of refuge (Josh. xx., 7). Abimelech, son of Gideon, was for a space ruler in Shechem (Judges viii., 31). Rehoboam's foolish speech there set the northern kingdom on fire; and Jeroboam made it his headquarters (I Ki. xii.). The rise of Samaria (*q.v.*) threw Shechem into the shadow and it disappears from history during the latter part of the Hebrew monarchy. The rise of the Samaritan community from the colonists settled by Sargon and Ashurbanipal, and the downfall of Samaria contributed to its resurrection. To Josephus it was Neapolis (whence modern Nāblus) or Flavia, so called to commemorate its restoration by Titus Flavius Vespasian.

A bishopric was set up at Neapolis and a Samaritan attack on him (A.D. 474) was punished by Zeno, who gave Gerizim (*q.v.*) to the Christians. Captured by crusaders (1099), it was lost to Saladin (1184), the church the crusaders had built being converted into a mosque. The soldiery of Ibrahim Pasha pillaged the town in 1834. On Sept. 21, 1918, it was occupied by British troops.

Archaeology.—Shechem is the traditional site of the tomb of Joseph. One and a half miles on the way to Jerusalem is the well of Jacob, an identification most probably authentic. The "sacred oak" (Gen. xxv., 4) has been sought at El 'Amūd, and at Balāta less than a mile from the town to the east. Excavations now in progress (1928) at Balāta have revealed a blunt topped pyramid, 131 ft. square and 16 ft. high, part evidently of a tower in the fortifications. Near to it were found cubical cellars resembling corn granaries such as were found at Pithom in Egypt. Below the fortifications are traces of an older city dating from 1700 B.C. It was seemingly destroyed in 1300 B.C. The Balāta site is now identified with Migdal-Schechem ("tower of Shechem," Judges ix., 49). Other discoveries there include the remains of a palace (18th century B.C.), a temple (to Baal-Berith?) and two cuneiform tablets, one containing a list of witnesses and the other a letter. (E. Ro.)

SHEE, SIR MARTIN ARCHER (1770–1850), Irish portrait painter, was born in Dublin on Dec. 23, 1770. He studied in the Academy schools, became A.R.A. in 1798, and R.A. in 1800. Besides his many excellent portraits, he painted various subject and historical works. He succeeded Lawrence as president of the Academy in 1830. He died on Aug. 13, 1850.

SHEEP. Little is known with certainty about the origin of domesticated sheep. The earlier writers assumed a hypothetical wild ancestor having a long tail and certain other characteristics that distinguish the majority of domesticated breeds from the existing wild species; but none of these characters is of real significance, and the more probable view is that the ancestors of our modern sheep belonged to species that still survive.

Dr. J. U. Duerst, from evidence collected on the site of the City of Anau in Turkistan, believes that the urial (*Ovis vignei*) was domesticated there, and he considers that the earliest domesticated European type (*Ovis aries palustris*) was directly derived from this stock. The latter animal, known as the turbary sheep, appeared in Europe in neolithic times and it survives, but little changed, in the Bündnerschaf or Nalperschaf of the Grisons. It is a small, slender limbed sheep, black faced, and with long, sharp-edged and rather goat-like horns. In the Copper age a new breed (*Ovis aries studeri*) with massive spiral horns, appeared in Europe, and Duerst has shown that this was almost certainly derived in part at least from the wild mouflon (*Ovis musimon*). In Sardinia, as has been known since the time of Pliny, the mouflon interbreeds freely with domesticated sheep. The bulk of our modern breeds are obviously much more closely related to the sheep of the Copper age than to the earlier turbary type; while it thus seems likely that the mouflon played the major part and the urial a minor part in producing our farm flocks, it is by no means certain that other species, such as the argali (*Ovis ammon*) were not concerned. Dr. Keller's theory, however, which derived the turbary sheep from the arui or udad (*Ammotragus*) of northern Africa has been shown to be quite untenable. (*See* also ARGALI, MOUFLON, UDAD.) (J. A. S. W.)

Characteristics of Sheep.—Sheep belong to the family of hollow-horned ruminants or Bovidae (*q.v.*). Practically they form a group impossible of definition, as they pass imperceptibly into the goats. Both sexes usually possess horns, but those of the females are small. In the males the horns are generally angulated, and marked by fine transverse wrinkles; their colour being greenish or brownish. They are directed outwards, and curve in an open spiral, with the tips directed outwards. Although there may be a fringe of hair on the throat, the males have no beard on the chin; and they also lack the strong odour characteristic of goats. Usually the tail is short; and in all the wild species the outer coat takes the form of hair, though beneath lies a short undercoat of fine wool, which has been developed into the fleece of domesticated races. Like goats, sheep have narrow upper molar teeth, very different from those of the oxen, and narrow hairy muzzles. Between the two middle toes, in most species, is lodged a deep glandular bag having the form of a retort with a small external orifice, which secretes an unctuous and odorous substance. This, tainting the herbage or stones over which the animal walks, affords the means by which, through the powerfully developed sense of smell, the neighbourhood of other individuals of the species is recognized. The crumen or suborbital face-gland, which is so largely developed and probably performs the same office in some antelopes and deer, is present, although in a comparatively rudimentary form, in most species, but is absent in others. Wild sheep attain their maximum development, both in respect of number and size, in Central Asia. They associate either in large flocks, or in family-parties; the old males generally keeping apart from the rest. Although essentially mountain animals, sheep generally frequent open, undulating districts, rather than the precipitous heights to which goats are partial. It may be added that the long tails of most tame breeds are, like wool, in all probability the results of domestication.

Varieties and Distribution.—The Pamir plateau, on the confines of Turkistan, at an elevation of 16,000 ft. above the sea-level, is the home of the magnificent *Ovis poli*, named after the celebrated Venetian traveller Marco Polo, who met with it in the 13th century. It is remarkable for the great size of the horns of the old rams and the wide open sweep of their curve, so that the points stand boldly out on each side, far away from the animal's head, instead of curling round nearly in the same plane, as in most of the allied species. A variety inhabiting the Thian Shian is known as *O. poli karelini*, and other racial forms occur in the mountains and lower ground of Turkistan, and in Central Asia. An even larger animal is the argali, *O. ammon*, typically from the Altai, but represented by one race in Ladak and Tibet (*O. ammon hodgsoni*), by a second in eastern Mongolia and by a third in the Desert of Gobi. Although its horns are less extended laterally than those of *O. poli*, they are grander and more massive. In their short summer coats the old rams of both species are nearly white. *Ovis sairensis* from the Sair mountains and *O. littledalei* from Kulja are closely allied forms. In the Stanovoi mountains and neighbouring districts of E. Siberia and in Kamchatka occur two sheep which have been respectively named *O. borealis* and *O. nivicola*. They are, however, so closely allied to the so-called bighorn sheep of N. America, that they can scarcely be regarded as more than local races of *O. canadensis*, or *O. cervina*, as some naturalists prefer to call the species. These bighorns are characterized by the absence of face-glands, and

BY COURTESY OF AMERICAN MUSEUM OF NATURAL HISTORY

THE OVIS POLI OF TURKISTAN, REMARKABLE FOR THE GREAT SIZE OF THE HORNS

the comparatively smooth front surface of the horns of the old rams, which are thus very unlike the strongly wrinkled horns of the argali group. The typical bighorn is the khaki-coloured and white-rumped Rocky Mountain animal; but on the Stickin river there is a nearly black race, with the usual white areas (*O. canadensis stonei*), while this is replaced in Alaska by the nearly pure white *O. c. dalli*; the grey sheep of the Yukon (*O. c. fannini*) being perhaps not a distinct form. Other geographical races of the bighorn, distinguished chiefly by the colour of the coat, include the mountain sheep of Mexico, of Lower California, of Upper Missouri, and of the Kenai Peninsula. Returning to Asia, we find in Ladak, Astor, Afghanistan and the Punjab ranges, a sheep whose local races are variously known as urin, urial and shapo, and whose technical name is *O. vignei.* It is a smaller animal than the members of the argali group, and approximates to the Armenian and the Sardinian wild sheep or mouflon (*Ovis orientalis* and *O. musimon*). (*See* MOUFLON.) We have in Tibet the bharal or blue sheep, *Ovis* (*Pseudois*) *bharal,* and in N. Africa the udad or aoudad, *O.* (*Ammotragus*) *lervia,* both of which have no face-glands and in this and their smooth horns approximate to goats. (*See* BHARAL and UDAD.)

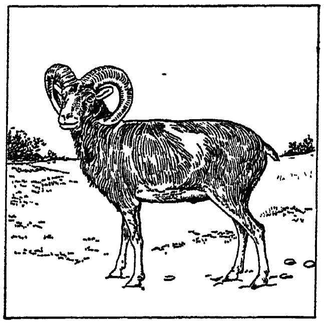
The sheep was domesticated in Asia and Europe before the dawn of history, though unknown in this state in the New World until after the Spanish conquest. It has now been introduced by man into almost all parts of the world where agricultural operations are carried on, but flourishes especially in the temperate regions of both hemispheres. The variations of external characters seen in the different breeds are very great. They are chiefly manifested in the form and number of the horns, which may be increased from the normal two to four or even eight, or may be altogether absent in the female alone or in both sexes; in the shape and length of the ears, which often hang pendent by the side of the head; in the peculiar elevation or arching of the nasal bones in some eastern races; in the length of the tail, and the development of great masses of fat at each side of its root or in the tail itself; and in the colour and quality of the fleece.

On the west coast of Africa two distinct breeds of hairy sheep are indigenous, the one characterized by its large size, long limbs and smooth coat, and the other by its inferior stature, lower build and heavily maned neck and throat. Both breeds, which have short tails and small horns (present only in the rams), were regarded by the German naturalist Fitzinger as specifically distinct from the domesticated *Ovis aries* of Europe; and for the first type he proposed the name *O. longipes* and for the second *O. jubata.* Although such distinctions may be doubtful (the two African breeds are almost certainly descended from one ancestral form), the retention of such names may be convenient as a provisional measure.

BY COURTESY OF THE CANADIAN NATIONAL RAILWAYS
THE ROCKY MOUNTAIN BIGHORN (OVIS CANADENSIS), A WILD SHEEP THAT HAS NEVER BEEN DOMESTICATED

The long-legged hairy sheep, which stands a good deal taller than a Southdown, ranges, with a certain amount of local variation, from lower Guinea to the Cape. In addition to its long limbs, it is characterized by its Roman nose, large (but not drooping) ears, and the presence of a dewlap on the throat and chest. The ewes are hornless, but in Africa the rams have very short, thick and somewhat goatlike horns. On the other hand, in the west Indian breed, which has probably been introduced from Africa, both sexes are devoid of horns. The colour is variable. In the majority of cases it appears to be pied, showing large blotches of black or brown on a white ground; the head being generally white with large black patches on the sides, most of the neck and the fore-part of the body black, and the hind-quarters white with large coloured blotches. On the other hand, these sheep may be uniformly yellowish white, reddish brown, greyish brown or even black. The uniformly reddish or chestnut-brown specimens approach most nearly to the wild mouflon or urial in colour, but the chestnut extends over the whole of the underparts and flanks; domestication having probably led to the elimination of the white belly and dark flank band, which are doubtless protective characters. The feeble development of the horns is probably also a feature due to domestication.

In Angola occurs a breed of this sheep which has probably been crossed with the fat-tailed Malagasy breed; while in Guinea there is a breed with lappets, or wattles, on the throat, which is probably the result of a cross with the lop-eared sheep of the same district. The Guinea lop-eared breed, it may be mentioned, is believed to inherit its drooping ears and throat wattles from an infusion of the blood of the Roman-nosed hornless Theban goat. (*See* GOAT.) Hairy long-legged sheep are also met with in Persia, but are not pure-bred, being apparently the result of a cross between the long-legged Guinea breed and the fat-tailed Persian sheep.



A SARDINIAN MOUFLON SHEEP

The maned hairy sheep (*Ovis jubata*), which appears to be confined to the west coast of Africa, takes its name from a mane of longish hair on the throat and neck; the hair on the body being also longer than in the ordinary long-legged sheep. This breed is frequently black or brown and white; but in a small sub-breed from the Cameroons the general colour is chestnut or foxy red, with the face, ears, buttocks, lower surface of tail and under-parts black. The most remarkable thing about this Cameroon sheep is, however, its extremely diminutive size, a full-grown ram standing only 19 in. at the withers.

In point of size this pigmy Cameroon breed comes very close to an exceedingly small sheep of which the limb-bones have been found in certain ancient deposits in the south of England; and the question arises whether the two breeds may not have been nearly related. Although there are no means of ascertaining whether the extinct pigmy British sheep was clothed with hair or with wool, it is practically certain that some of the early European sheep retained hair like that of their wild ancestor; and there is accordingly no prima facie reason why the breed in question should not have been hairy. On the other hand, since the so-called peat-sheep of the prehistoric Swiss lake-dwellers appears to be represented by the existing Graubünden (Grisons) breed, which is woolly and coloured something like a Southdown, it may be argued that the former was probably also woolly, and hence that the survival of a hairy breed in a neighbouring part of Europe would be unlikely. The latter part of the argument is not very convincing, and it is legitimate to surmise that in the small extinct sheep of the south of England we may have a possible relative of the pigmy hairy sheep of west Africa.

Fat-rumped sheep, *Ovis steatopyga,* are common to Africa and Asia, and are piebald with rudimentary horns, and a short hairy coat, being bred entirely for their milk and flesh. In fat-tailed sheep, on the other hand, which have much the same distribution, the coat is woolly and generally piebald. Four-horned sheep are common in Iceland and the Hebrides, and in early historic times they occurred frequently in the sheep flocks then present in lowland Scotland. There is another four-horned breed, distinguished by its black (in place of brown) horns, whose home is probably S. Africa. In the unicorn sheep of Nepal or Tibet the two horns of the rams are completely welded together. In the Himalayan and Indian hunia sheep, the rams of which are specially trained for fighting, and have highly convex foreheads, the tail is short at birth. Most remarkable of all is the so-called Wallachian sheep, or Zackelschaf (*Ovis strepsiceros*), represented by several more or less distinct breeds in eastern Europe, in which the long upright horns are spirally twisted in a manner similar to those of the markhor wild goat.

MODERN BRITISH BREEDS OF SHEEP

The sheep native to the British Isles are commonly grouped into longwool, shortwool and mountain breeds.

Longwools receive their name because of their long lustre wool; they are white-faced (except the Wensleydale) and hornless; their mutton tends to become rather fat, but this quality makes them useful for crossing with lean fleshed breeds, *e.g.*, the Merino. The longwool breeds are the Leicester, Border Leicester, Wensleydale, Cotswold, Lincoln, Devon Longwool, South Devon, Roscommon and Kent or Romney Marsh.

The *Shortwools* include the Down breeds all of which are hornless and have dark faces and legs, short dense wool of fine quality, and very good mutton. They are the Southdown, Shropshire, Suffolk, Hampshire Down, Dorset Down and Oxford Down. The other Shortwool breeds are the Dorset Horn, Western or Wiltshire Horn, Ryeland, Devon Closewool, Kerry Hill and Clun Forest.

The *Mountain* breeds are relatively small hardy sheep which produce mutton of fine quality. They are the Scotch Blackface, Swaledale, Lonk, Rough Fell, Derbyshire Gritstone, Cheviot, Welsh Mountain, Herdwick, Exmoor Horn, Dartmoor and Shetland.

The *Leicester* is of high interest. It was the breed which Robert Bakewell, the pioneer stock improver, took in hand in the 18th century, and developed by the exercise of his skill and judgment. In past times Leicester blood was extensively employed in the improvement or establishment of other longwool breeds of sheep. The Leicester, as seen now, has a white wedge-shaped face with a few dark spots, the forehead covered with wool; thin mobile ears; neck full towards the trunk, short and level with the back; width over the shoulders and through the heart; a full broad breast; fine clean legs standing well apart; deep round barrel and great depth of carcass; firm flesh, springy pelt, and pink skin, covered with long, fine, curly, lustrous wool. The breed is now chiefly centred in east and north Yorkshire and Durham, but its chief value is for crossing, when it is found to promote maturity and to improve the fattening propensity.

The *Border Leicester* originated after the death in 1795 of Bakewell, when the Leicester breed, as it then existed, diverged into two branches. The one is represented by the breed still known in England as the Leicester. The other, bred on the Scottish Borders, with possibly an early admixture of Cheviot blood, acquired the name of Border Leicester.

The *Wensleydales* take their name from the Yorkshire dale of which Thirsk is the centre. They are longwool sheep, derived from the old Teeswater breed by crossing with Leicester rams. They have a tuft of wool on the forehead. The skin of the body is sometimes blue, whilst the wool has a very bright lustre, is curled in small distinct pirls, and is of uniform staple. The rams are in much favour in the N. of England for crossing with ewes of the various black-faced horned mountain breeds to produce mutton of superior quality and to use the cross-ewes to breed to a pure longwool or sometimes a Down ram.

The *Cotswold* is an old-established breed of the Gloucestershire hills, extending thence into Oxfordshire. It was but slightly crossed for improvement by the Dishley Leicesters and has retained its characteristic type for generations. They are useful for crossing purposes to impart size, and because they are exceptionally hardy.

The *Lincolns* are descended from the old native breed of Lincolnshire, improved by the use of Leicester blood. They are the largest and most massive British breed and they are quite hardy. Breeders of Lincoln rams like best a darkish face, with a few black spots on the ears; and white legs. The wool has a broad staple, and is denser and longer, and the fleece heavier, than in any other British breed. For this reason it has been the breed most in favour with breeders in all parts of the world for mating with Merino ewes and their crosses. The progeny is a good general-purpose sheep, giving a large fleece of wool but only a medium quality of mutton. With a greater proportion of Lincoln blood in the mixed flocks of the world there is a growing tendency to produce finer mutton by using Down rams, but at the sacrifice of part of the yield of wool.

The *Devon Longwool* is a breed locally developed in the valleys of W. Somerset, N. and E. Devon, and parts of Cornwall. It originated in a strong infusion of Leicester blood amongst the old Bampton stock of Devonshire.

The *South Devon* was developed from an old local breed by crossing with the Leicester. The animals are large and hardy and their mutton is said to be superior to the average longwool quality; they produce a heavy, valuable fleece.

The *Roscommon*—the one breed of modern sheep native to Ireland—is indebted for its good qualities largely to the use of Leicester blood.

The *Kent* or *Romney Marsh* is native to the rich tract of grazing land on the S. coast of Kent. They are hardy, short-legged, thickly-made, white-faced sheep, with a close-coated longwool fleece. They were gradually, like the Cotswolds, improved from the original type of slow-maturity sheep by selection in preference to the use of rams of the Improved Leicester breed. With the exception of the Lincoln, no breed has received greater distinction in New Zealand, where it is in high repute for its hardiness and general usefulness. When difficulties relating to the quantity and quality of food arise the Romney is a better sheep to meet them than the Lincolns or other longwools.

The *Oxford Down* is a modern breed which owes its origin to crossing between Cotswolds and Hampshire Downs and Southdowns. Although it has inherited the forelock from its longwool ancestors, it approximates more nearly to the shortwool type, and is accordingly classified as such; it is the largest and heaviest of the Down breeds. The rams are largely used for crossing in Scotland, particularly with Border Leicester-Cheviot ewes.

The *Southdown,* from the short close pastures upon the chalky soils of the South Downs in Sussex, was formerly known as the Sussex Down. In past times it did for the improvement of the shortwool breeds of sheep very much the same kind of work that the Leicester performed in the case of the longwool breeds. A pure-bred Southdown sheep has a small head, with a light brown or brownish grey (often mouse-coloured) face, fine bone, and a symmetrical, well-fleshed body. The legs are short and neat, the animal being of small size compared with the other Down sheep. The fleece is of fine, close, short wool, and the mutton is excellent. "Underhill" flocks that have been kept for generations in East Anglia, on the Weald, and on flat meadow land in other parts of the country, have assumed a heavier type than the original "upperdown" sheep. It was at one time thought not to be a rent-paying breed, but modern market requirements have brought it well within that category.

The *Shropshire* is descended from the old native sheep of the Salopian hills, improved by the use of Southdown blood. Though heavier in fleece and a bulkier animal, the Shropshire resembles an enlarged Southdown. As distinguished from the latter, however, the Shropshire has a darker face, blackish brown as a rule, with very neat ears, whilst its head is more massive, and is better covered with wool on the top and at the sides. The Shropshire is the most popular mutton sheep in the corn belt and Great Lakes regions of the United States.

The *Hampshire Down.*—Early in the 19th century the old Wiltshire white-faced horned sheep, with a scanty coat of hairy wool, and the Berkshire Knot, roamed over the downs of their native counties, and the Hampshire was evolved by blending these types with the blood of the Southdown. The Wiltshire horned sheep still survives as a pure breed. Early maturity and great size have been the objects aimed at and attained, this breed, more, perhaps than any other, being identified with early maturity. One reason for this is the early date at which the ewes take the ram. Whilst heavier than the Shropshire, the Hampshire Down sheep is less symmetrical. It has a black face and legs, a big head with Roman nose, darkish ears set well back, and a broad level back (especially over the shoulders) nicely filled in with lean meat.

The *Dorset Down* or *West Country Down,* "a middle type of

Down sheep pre-eminently suited to Dorsetshire," is a local variety of the Hampshire Down breed, separated by the formation of a Dorset Down sheep society in 1904.

The *Suffolk* is another Down, which took its origin about 1790 in the crossing of improved Southdown rams with ewes of the old black-face Horned Norfolk. The characteristics of the latter are retained in the black face and legs of the Suffolk, but the horns have been bred out. The fleece is moderately short, the wool being of typical Down quality. Owing to its fine quality of mutton the Suffolk competes very strongly with the best mutton breeds—*e.g.*, the Southdown—in carcass competitions; it has secured notable successes at Smithfield and at the Scottish National Fat Stock Show.

The *Dorset Horn* is an old west-country breed of sheep. This is a hardy breed, in size somewhat exceeding the Southdown. The special characteristic of the breed is that the ewes take the ram at an unusually early period of the year, and cast ewes are in demand for breeding house lamb for Christmas. The *Ryeland* breed is so named from the Ryelands, a poor upland district in Herefordshire. It is a hardy grassland breed which is neither very quick maturing nor particularly prolific.

The *Clun Forest* is a local breed in west Shropshire and the adjacent part of Wales. It is descended from the old Tan-faced sheep. It is now three parts Shropshire, having been much crossed with that breed.

The *Western* or *Wiltshire Horned* sheep is an old breed that has recently been revived. It is not unlike the Dorset Horn but it has even stronger horns in both sexes and is peculiar in that it carries practically no wool. The skin shows a considerable number of small black spots. The sheep are very hardy and they are useful for grassland farms where it is undesirable to apply the intensive system of management customary with Down flocks.

The *Devon Closewool* was originated in North Devon by blending the blood of Devon Longwools with Exmoor Horns. The size is intermediate between the parent breeds and the animals are short in the leg and thickly made. The sheep are very well suited to commercial purposes on land of intermediate quality.

The *Kerry Hill* is a brown and white speckled faced breed found along the Welsh border. Kerry hills are hardy grass sheep; the ewes are often crossed with Shropshires to produce fat lambs, while on the other hand the rams are often used for crossing with Welsh Mountain ewes.

The *Cheviot* is a hardy sheep with straight wool, of moderate length and very close-set. Put to the Border Leicester ram the Cheviot ewe produces the *Half-bred*, which as a breeding ewe is unsurpassed as a rent-paying, arable-land sheep.

The *Scotch Blackface* breed is chiefly reared in Scotland, but it is of N. of England origin. Their greater hardiness, as compared with the Cheviots, has brought them into favour upon the higher grounds of the N. of England and of Scotland, where they thrive upon heather hills and coarse and exposed grazing lands. The colour of face and legs is well-defined black and white, the black predominating. The spiral horns are low at the crown, with a clear space between the roots, and sweep in a wide curve, sloping slightly backwards, and clear of the cheek. The fashionable fleece is down to the ground, hairy and strong, and of uniform quality throughout.

The *Lonk* has its home amongst the moorlands of N. Lancashire and the W. Riding of Yorkshire, and it is the largest of the mountain breeds of the N. of England and Scotland.

The *Herdwick* is the hardiest of all the breeds; it thrives upon the poor mountain land in Cumberland and Westmorland. The rams generally have small, curved, wide horns; the ewes are hornless.

The *Welsh Mountain* is a small, active, soft-woolled, white-faced breed of hardy character. The legs are often yellowish, and this colour may extend to the face. Horns occur only in the males. The mutton is of excellent quality. The ewes, although difficult to confine by ordinary fences, are in high favour in lowland districts for breeding fattening lambs to Down and other early maturity rams.

The *Dartmoor*, a hardy local Devonshire breed, is a large hornless, longwool, white-fleeced sheep, with a long mottled face. It has been attracting attention in recent years. It is intermediate in type between a mountain and a Longwool breed.

The *Exmoor* is a horned breed of Devonshire moorland, one of the few remaining remnants of direct descent from the old forest breeds of England. They have white legs and faces and black nostrils. The coiled horns lie more closely to the head than in the Dorset and Somerset Horn breed. The Exmoors have a close, fine fleece of short wool. They are very hardy, and yield mutton of choice flavour.

The *Swaledale* is one of the larger sized breeds of the Blackface or heath type; it is native to Yorkshire. It is horned; its face is dark with a light or "mealy" nose.

The *Rough Fell* is a Westmorland breed belonging to the Blackface heath group. The ewes are frequently crossed with the Wensleydale and the cross-breeds form valuable feeding sheep for poor and exposed conditions.

The *Derbyshire Gritstone* is a hornless breed with black and white mottled face and legs; it is native to the hills and dales of the millstone grit formation. The animals are hardy and their wool is the finest and closest of any heath breed. The mutton is typical of hill sheep being lean and of fine flavour.

The *Shetland* is a small sized sheep which is found in the islands whose name it bears. The colours are variable, white, black and rich brown all being common. The animals are very hardy and can subsist on poor fare. The outstanding quality of the breed is its extraordinary fine soft wool which has a very high value. The breed is slow to mature and very thin fleshed.

Other Breeds of Sheep.—The *Merino* is the most widely distributed sheep in the world. The breed is indigenous to Spain but the modern Merino has been largely developed and improved in Australia and the United States. The breed suits countries with a relatively small rainfall, although it is adapted to a wide variety of climatic conditions. The outstanding product of the Merino is its very fine close wool. The mutton is palatable and nutritious but the carcasses average less plump and fat than those of mutton type sheep such as the Downs and Longwools. While pure Merinos are kept in the poorest and driest districts abroad, on better land the flocks are frequently crossed with Longwools, thereby greatly improving the quality of the carcass without seriously injuring the value of the wool. On still better land Down breeds are bred to the Merino-Longwool crosses and give a very good mutton carcass fit for exportation.

The Merino is white-faced and has a flesh-coloured nose; its wool has no coloured fibres. The illustration shows a modern type of Australian Merino. There are in fact a number of well recognized types varying from small, thin-fleshed animals with very wrinkled skins and extra fine wool to relatively large, smooth sheep producing barely such fine wool but possessing better mutton qualities.

The *Corriedale* is a Lincoln-Merino cross which in New Zealand has been fixed as a pure breed. It combines a splendid fleece with a good constitution and a good commercial mutton carcass.

Lowland Sheep-breeding and Feeding.—A Shropshire flock of about 200 breeding ewes is here taken as a typical example of the numerous systems of managing sheep on a mixed farm of grazing and arable land. The ewes lamb from early in January till the end of February. The lambs have the shelter of a lambing shed for a few days. When drafted to an adjoining field they run in front of their mothers and get a little crushed oats and linseed cake meal, the ewes receiving kail (kale) or roots and hay to develop milk. Swedes gradually give place to mangolds, rye and clover before the end of April, when shearing of the ewe flock begins, to be finished early in May. At this time unshorn lambs are dipped and may be dosed with medicine to destroy internal parasites. The operation is repeated in September. The lambs are weaned towards the end of June and the ewes run on the poorest pasture till August to dry off their milk. In August the ewes are culled and the flock made up to its full numbers by selected shearling ewes. All are assorted and mated to suitable rams. Most of the older ewes take the ram in September, but maiden or yearling ewes are kept back till October. During the

6. Cooling room of a freezing works in New Zealand filled with sheep carcasses that will be frozen thoroughly for export

rest of the year the ewes run on grass and receive hay when necessary, with a limited amount of dry artificial food daily, ¼ lb. each, gradually rising as they grow heavy in lamb to 1 lb. per day. Turnips before lambing, if given in liberal quantities, are an unsafe food. To increase the number of doubles, ewes are sometimes put on good fresh grass, rape or mustard a week or two before the tups (breeding rams) go out—a ram to 60 ewes is a usual proportion, though with care it is possible to get a stud ram to settle twice that number. With good management 20 ewes of any of the lowland breeds should produce and rear thirty lambs, and the proportion can be increased by breeding from ewes with a prolific tendency. The period of gestation of a ewe is between 21 and 22 weeks, and the period of oestrum 24 hours. If not settled the ewe comes back to the ram in from 13 to 18 (usually 16) days. To indicate the time or times of tupping (breeding) three colours of paint are used. The breast of the ram is rubbed daily for the first fortnight with blue, for a similar period with red, and finally with black.

Fattening tegs (sheep approximately one year old that have never been sheared) usually go on to soft turnips in the end of September or beginning of October, and later on to yellows, green-rounds and swedes and, in spring and early summer, mangolds. The roots are cut into fingers and supplemented by an allowance of concentrated food made up of a mixture of ground cakes and meal, ¼ lb. rising to about ½ lb.; and ½ lb. to 1 lb. of hay per day. The dry substance consumed per 100 lb. live weight in a ration of ½ lb. cake and corn, 12 lb. roots and 1 lb. hay daily, would be 16½ lb. per week, and this gives an increase of nearly 2% live weight or 1 lb. of live weight increase for 8¼ lb. of dry food eaten. Sheep finishing at 135 lb. live weight yield about 53% of carcass or over 70 lb. each.

Management of Mountain Breeds.—Ewes on natural pastures receive no hand feeding except a little hay when snow deeply covers the ground. The rams come in from the hills on Jan. 1 and are sent to winter on low ground. Weak ewes, not safe to survive the hardships of spring, are brought in to better pasture during February and March. Ewe hogs (ewe lambs or yearlings that have never been sheared) wintered on grass in the low country from Nov. 1 are brought home in April, and about the middle of April on the average mountain ewes begin to lamb. One lamb at weaning time for every ewe is rather over the normal amount of produce. Cheviot and cross-bred lambs are marked, and the males are castrated, towards the end of May. Nearly a month later Blackface lambs are marked and the eild (mature) sheep are shorn—the shearing of milch ewes (ewes nursing lambs) being delayed till the second week of July. Towards the end of July sheep are all dipped to protect them from maggot flies (which are generally worst during August) with materials containing arsenic and sulphur. Fat wethers for the butcher are drafted from the hills in August and the two succeeding months. Lamb sales are most numerous in August, when lowland farmers secure their tegs to feed in winter. In this month breeding ewes recover condition and strength to withstand the winter storms. Ram auctions are on in September and draft ewe (a less desirable ewe sold from a stud flock) sales begin and continue through October. Early this month winter dipping is done at midday in dry weather. Early in November stock sheep having lost the distinguishing "buist" put on at clipping time with a large iron letter dipped in hot branding fluid, have the distinctive paint or kiel mark claimed by the farm to which they belong rubbed on the wool. The rams are turned out to the hills between Nov. 15 and 25. Lowland rams put to breed half-bred and cross lambs receive about 1 lb. of grain daily to prevent their falling off too rapidly in condition, as they would do if exclusively supported on mountain fare. (R. WA.; J. A. MO.)

American Sheep.—The established breeds of sheep in North America are of British, Spanish and French origin. The British breeds predominate in Canada and constitute considerably more than half of the pure-bred sheep in the United States. Mexico has shown more interest in Merinos and Rambouillets, which are of Spanish and French origin respectively. According to the 1920 census of pure-bred sheep in the United States, Shropshires made up 31% of those enumerated by breeds; Rambouillets, 27; Merinos, 15; Hampshires, 13; Oxfords and Lincolns, each 4; Dorsets and Southdowns, each 2. The remaining 2% included Cheviots, Leicesters and Suffolks. Romneys, Cotswolds, Corriedales and Karakuls are bred in the United States but are comparatively few and were not enumerated by breeds.

Shropshires are most numerous in the corn belt and Great Lakes regions; Rambouillets in the western range States, although they are also bred in some farm States, especially Ohio and Michigan. Merinos are most numerous in Ohio, West Virginia, Pennsylvania and Michigan, but they are also bred in other parts of the country, especially Oregon, California, New Mexico and Texas. Hampshires are most numerous in the western range country but are also important in farm States, notably New York, Pennsylvania, Michigan, Missouri, Kentucky and Virginia. Oxfords are found in the North-Central States; Lincolns in the Mountain and Pacific States; Dorsets in the Middle Atlantic and East North-Central States; Southdowns in Tennessee, Kentucky, West Virginia, Ohio, Pennsylvania and New York; Cheviots in New York; Leicesters principally in the North-East and North-Central States. Romneys, Cotswolds, Corriedales, Suffolks and Karakuls are sparsely distributed in both farm and range areas.

Through selection these breeds have been modified to suit American conditions. Cross-breeding is also practised, especially in the western range country where forage is sufficiently abundant for finishing lambs by weaning time without grain. Under such conditions Rambouillet ewes are often bred to Lincoln or Hampshire rams and Lincoln-Rambouillet cross-bred ewes to Hampshire rams for the production of market lambs. Lincoln-Rambouillet cross-bred sheep are proving well adapted to this kind of range sheep production and the U.S. Department of Agriculture has been endeavouring since 1912 to establish this type by mating the cross-bred ewes to the cross-bred rams. The progress made is encouraging and this type is now known as the Columbia. Corriedales are the result of interbreeding Lincoln-Merino cross-breds in New Zealand and they have been bred in the United States since 1914. While they are smaller than the Columbia they are similar in type and produce lambs and wool of excellent quality. Karakuls are bred for their famous lamb skins of tight, lustrous curls. (D. A. S.)

SHEEPSHEAD, one of the large species of the genus *Archosargus.* These fishes possess two kinds of teeth: one, broad and flat, like incisors, in a single series in the front of the jaws; the other, semiglobular and molar-like, in several series on the sides of the jaws. The genus belongs to the acanthopterygian family *Sparidae* which includes the sea-breams. The common sheepshead occurs in abundance on the Atlantic coasts of the United States, from *Cape Cod to Florida,* and is one of the most valued food-fishes of North America. It may attain a length of 30in. and a weight of 15lb. Its food consists of shellfish, which it detaches with its incisors, then crushing them with its powerful molars. It may be distinguished from allied species by its seven or eight dark cross-bands. The term "sheepshead" is also given in some parts of North America to a freshwater sciaenoid, *Corvina oscula.*

SHEEPSHEAD (ARCHOSARGUS PROBATOCEPHALUS), A FOOD FISH FOUND ALONG THE EASTERN COAST OF NORTH AMERICA

SHEEP SHEARING MACHINES. In countries where individual flocks of sheep are large or where wages are high, mechanical aids to hand clipping are employed in order to lower the cost or to speed up the work. In the pastoral districts of Australia, New Zealand and South America mechanical shearing

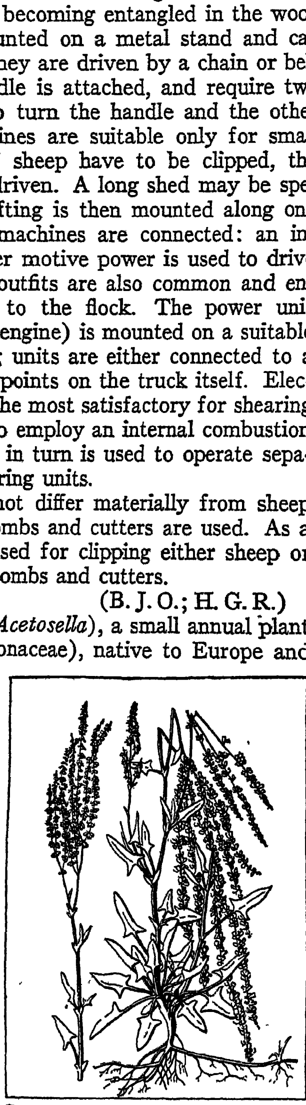
is almost universal. In Great Britain, although hand clipping is still widely practised, the use of shearing machines is gradually extending. Hand-shearing leaves the clipped surface in ridges whose evenness and symmetry are an indication of the skill of the operator while the machine leaves the surface level. It is claimed that the machine clips a heavier fleece than hand shears; but the result depends largely on the comparative skill of the operators.

The essential components of a shearing machine are a comb which is guided by hand over the body of the animal, a cutter with sharp edges which shears the wool by passing backwards and forwards across corresponding edges on the comb, a reciprocating device for actuating the cutter, a flexible or universally jointed coupling for driving the cutter, and the hand wheel or power unit. The moving parts of the actuating mechanism are protected so as to prevent them becoming entangled in the wool. Hand machines are usually mounted on a metal stand and can be easily carried by one man. They are driven by a chain or belt from a wheel to which the handle is attached, and require two persons to operate them, one to turn the handle and the other to clip the sheep. These machines are suitable only for small flocks. When large numbers of sheep have to be clipped, the machines are invariably power driven. A long shed may be specially adapted for shearing: shafting is then mounted along one side to which several shearing machines are connected: an internal combustion engine or other motive power is used to drive the shafting. Portable shearing outfits are also common and enable the machine to be taken to the flock. The power unit (usually an internal combustion engine) is mounted on a suitable transport truck and the shearing units are either connected to a portable shafting or to separate points on the truck itself. Electric drive has been found to be the most satisfactory for shearing machines and it is not unusual to employ an internal combustion engine to drive a dynamo which in turn is used to operate separate motors for driving the shearing units.

Horse clipping machines do not differ materially from sheep shearing machines but special combs and cutters are used. As a rule shearing machines can be used for clipping either sheep or horses by merely changing the combs and cutters.

(B. J. O.; H. G. R.)

SHEEP SORREL (*Rumex Acetosella*), a small annual plant of the buckwheat family (Polygonaceae), native to Europe and Asia, and found in gravelly soil in the British Isles. It is widely naturalized in North America, often becoming a pestiferous weed in pastures, meadows and fields. It grows usually less than 1 ft. high, with smooth acid herbage, the leaves narrowly, lance-shaped or halberd-form. The small dioecious flowers, which appear in spring, are borne in a narrow terminal cluster (panicle).



SHEEP SORREL, A HARDY SUMMER WEED OF THE TEMPERATE ZONE

SHEERNESS, a garrison town and naval seaport in the Faversham parliamentary division of Kent, England, in the Isle of Sheppey, on the right bank of the Medway estuary at its junction with the Thames, with a goods station on the S.R. Pop. (1931), 16,721. Blue Town, the older part, with the dockyard, is defended by strong modern-built fortifications, especially the forts of Garrison Point and Barton's Point, commanding the entrance of both the Thames and the Medway. The dockyard, chiefly used for naval repairs, covers about 60 ac., and consists of three basins and large docks, the depth of water in the basins ranging down to 26 feet. Within the yard there are extensive naval stores and barracks. Outside the dockyard are the residences of the admiral of the home fleet and other officers, and barracks. The harbour is spacious, sheltered and deep even at low water. Sheerness has some trade in corn and seed, and in supplying shipping. There is steamboat connection with Port Victoria, on the opposite side of the Medway; with Southend, on the opposite side of the Thames; and with Chatham and London, and the town is in some favour as a seaside resort. A small fort was built at Sheerness by Charles II., which, on July 10, 1667, was taken by the Dutch fleet under De Ruyter.

SHEETS, IRON AND STEEL. The production of rolled sheet iron dates back before 1620 in Bohemia and was introduced in Wales in 1720. (*See* TIN-PLATE AND TERNE PLATE.) Most of the rolling was done by hand, and great skill was required. The sheets were usually made of puddled or wrought iron. Upon the development of the Bessemer (*q.v.*) process and the open hearth (*q.v.*) process, steel was produced more rapidly and cheaply and practically replaced iron. However, steel sheets showed shorter service life under corrosive conditions, and interest in sheet iron reawakened. Metallurgists found methods of manufacturing it in larger quantities and less laboriously. To-day iron sheets are generally available and marketed at prices not greatly different from those of steel sheets.

Production.—In the production of sheets, the first part of the process is much the same as that employed for plates, sections and other products. The metal is refined, teemed into ingot moulds, heated again in soaking pits, and the ingots reduced in the blooming (or cogging) mill. The "bloom" is reduced in size and increased in length by its passage through rolls in the bar mill. The slabs that come from the blooming mill are cut up into bars of the proper length, which length becomes the width of the sheet to be later rolled from these bars. The bars are usually produced in two widths: 12 in. and 8 inches. The thickness in the bar governs the gauge of the sheet it will make.

"Roughing down" the bars is the next step. They are put through roughing mills to reduce them to the proper gauge to go into the finishing mills. This laborious work has been eliminated in some plants by the "continuous process." This process, introduced in 1923, makes it possible to roll the slabs as they come from the blooming operation. As they go from one mill to another, each succeeding mill turns slightly faster and rolls the metal thinner. Along the route are heating furnaces designed to keep the slabs at proper temperatures for rolling. The development of the continuous process makes possible a reduction of the ingots to sheets approximately ·06 in. thick without the metal being manipulated by hand. The iron is converted into a long, thin strip which is coiled while still hot as it comes from the mill. The coiled material is cut into lengths that correspond exactly to the roughed down sheet. The sheets are then matched and placed in another furnace for reheating in advance of finishing. Some of the new type furnaces contain slowly moving conveyors that bring the sheets through for withdrawal at one end. They are then passed between the finishing rolls, the top one driven by friction against the bottom roll, which is coupled into the "roll train" drive.

Heavy sheets and light plates are rolled in what is usually known as a "jobbing mill." There are no essential differences between it and a sheet mill except that the former handles sheets and plates from 16 gauge to ½ inch.

Annealing and Pickling.—After the sheets come from the finishing rolls, it is necessary to anneal them because the grain structures have been very much disarranged. Box annealing, or open or blue annealing, is used. In the first, the sheets are stacked on cast steel plates and covered with an iron cover to exclude the air, then placed in large ovens under known temperatures and for definite periods of time, depending upon the kind of treatment desired. In the open annealing process, the sheets are passed under a brick hood open at both ends. As they are conveyed through this furnace, they are subjected to the open flame that comes in at the sides of the furnace. The controlling factors in this process are the varying temperatures in different parts of the furnace, and the speed of the different sections of the conveyor drive. The purpose of the pickling in diluted acid is to remove all dirt and scale. In some of the newer mills, the sheets are stitched or spot welded together and sent through the annealing furnaces very slowly so that they receive the necessary heat treat-

BY COURTESY OF THE AMERICAN ROLLING MILL COMPANY

PROCESSING SHEET METAL

1. Liquid steel being poured out of an open-hearth furnace into the ladle
2. An 11,000 lb. slab being conveyed from slabbing mill to furnace in the foreground
3. Slab being conveyed through the continuous mills to be compressed to a ribbon of sheet metal
4. Slab compressor in foreground, which reduces a slab to 200 ft. of sheet metal in about 20 seconds
5. Four high mills set in tandem, used to reduce metal to sheet form
6. Adjusting the rolls to proper thickness or gauge
7. Sheets cut to specified sizes ready for shipment
8. Huge magnets convey the metal, automatically coiled, to the warehouse, thence to the decoiler and shears

ment as they go. The endless chain of metal then comes out and goes through a continuous pickling process in the same manner.

Galvanizing.—If the sheets are to be galvanized they are coated with zinc in galvanizing pots. (*See* GALVANIZED IRON AND STEEL.) The speed of the exit rolls and the temperature of the zinc control the weight of coating. Zinc makes a very good coating for iron and steel because it forms an alloy bond with the iron.

Coating.—Paint is often used to cover galvanized iron. Best results are secured when the zinc is allowed to weather several months. A quicker way to prepare the zinc is to brush it with a special priming coat for painting, a dilute solution of acetic acid or vinegar, rinsing with water and allowing to dry. Bitumastic or asphalt coatings are also employed. They are especially valuable where erosion is encountered.

Special Finish Sheets.—Many sheets are not galvanized, but are given special finishes. They are cold rolled between highly polished or ground rolls to secure a high or smooth finish. They are often cold rolled to as much as one-third their previous thickness. In case the sheets are required to be absolutely flat, they are stretcher-levelled, being placed in large grips under hydraulic pressure and pulled from both ends to a point just beyond the "yield point."

Uses.—To name the industries that use iron and steel sheets would be to list practically every industry of importance. In general, galvanized sheets are used in exposed situations where corrosion is a factor. One of the largest uses is roofing and sheet metal work. Ungalvanized sheets are sold as black sheets and blue annealed. These are used in many fabricated products such as tanks, pipe, locomotive jackets and car siding. (*See* TIN-PLATE AND TERNE PLATE; GALVANIZED IRON AND STEEL.) (B. CHA.)

SHEFFIELD, a city, county and parliamentary borough in the West Riding of Yorkshire, England, 158½ m. N.N.W. of London, 42½ m. S.E. of Manchester and 53 m. S.W. of York. It is served by the L.M.S. and L.N.E. railways and has connection with all the principal towns in the North of England. Pop. (1931) 511,742. It is situated in the extreme south of the county at the foot of the Pennines and at the junction of the Don with its tributaries the Sheaf, the Porter, the Rivelin and the Loxley. These valleys provide easy routes N.W., W. and S.W. into the Pennines.

At the time of the Domesday Survey, Sheffield (Escafeld) was unimportant, forming with the manors of Grimesthorpe, Hallam and Attercliffe what is now the borough of Sheffield. Of these four manors Hallam was the most important, and gave its name to the shire. In 1296, a grant was made, to Hallamshire, of a market every Tuesday and an annual fair lasting three days, and in the following year the inhabitants were given a charter granting them the privileges as burgesses, of holding a court baron every three weeks, and of freedom from toll. By the end of the 14th century Sheffield had become more important than Hallam, partly no doubt on account of the castle built there in the 13th century. In the reign of Edward VI. certain property in the town which had been left to the burgesses in trust for charities was forfeited to the crown under the act for the suppression of colleges and chantries, but on their petition it was restored in 1554 by Queen Mary, who, at the same time, incorporated the town under the government of twelve capital burgesses. The town trust for the administration of property belonging to the town dates from the 14th century, and in 1681 the number and manner of election of the "town trustees" was definitely settled by a decree of the Court of Chancery. Additional powers were conferred on the trustees by an act passed in 1874. The town first returned members to parliament in 1832. In 1885 the representation was increased from two to five members, and since 1918, seven members have been returned. The county borough was created in 1888, in 1893 the town became a county borough and the title of Lord Mayor was conferred on the chief magistrate in 1897.

Manufactures.—Sheffield owes its prosperity to the manufacture of steel. In the valleys of the Don and its tributaries iron smelting from local ore by means of wood was carried on, probably by the Romans at Templeborough, and certainly at the time of the Norman Conquest. Later, water power was used to drive bellows for the provision of artificial draught and for this the upland streams which converge on Sheffield were important. The town had become famed for its cutlery by the 14th century and was a strong rival of London; local iron contained too much phosphorus and the cutlery trade throve chiefly on imported iron from Sweden and Spain. The Cutlers Company was formed in 1624. Local hard stone provided grinding wheels and even to-day much grinding is done by individual workers. In the 18th century, iron smelting was on the verge of ruin, owing to the exhaustion of local timber supplies, and outcrop coal from the South Yorkshire coalfield gave the industry a new lease of life. Coke replaced charcoal, clay and gannister were found locally, and gradually, as steam power superseded water power, the steel industry concentrated in the lower parts of the valley and the town of Sheffield grew rapidly. In early times, cutlery was made of blister or bar steel, later shear steel was used, but in 1740, Benjamin Huntsman introduced the manufacture of cast steel and upon this achievement many subsequent steel making discoveries have been based. It was with the aid of Sheffield capital that Henry Bessemer founded his pioneer works to develop the manufacture of his invention, and so revolutionised the industry by cheapening its production. Large quantities of Bessemer steel are still made in Sheffield. Further improvements in steel were made in 1858 and in 1882 manganese steel was introduced. Progress lagged until 1900 when it seemed America would capture the market. A still better type of high speed steel was then produced and the position of Sheffield was maintained.

The trade in heavy steel has kept place with that in other branches and armour plates, large castings for engines and ocean liners, hydraulic presses, rails, tyres, axles, stoves and grates, steel shot and steel for rifles are produced. Modern works dealing with heavy steel goods are located in the Don valley between its elbow and the town of Rotherham, near the easiest route to and from Sheffield, while cutlery and lighter metal goods are made on the higher sites to S. and W. The cutlery trade embraces almost every variety of instrument and tool—spring and table knives, razors, scissors, surgical and mathematical instruments, edge tools, saws, engineering and agricultural tools, etc. The art of silver-plating was introduced in 1742 and specimens of early Sheffield plate are highly prized. Among other industries of the town are tanning, confectionery, cabinet making, bicycle manufacture, iron and brass founding, manufacture of paper (due to the purity of the streams), printing and bookbinding, and making of optical instruments, brushes, horsehair cloth, railway fittings, chemicals and paint and varnish. The most recent developments are the manufacture of gramophones and needles, and nickel-silver cooking utensils which were introduced to England by a Sheffield firm in 1919. By acts of 1883–88, the Cutlers' Company exercises jurisdiction in all matters relating to the registration of trade marks, over all goods composed in whole or in part of any metal, wrought or unwrought, and also over all persons carrying on business in Hallamshire and within 6 m. thereof.

Communications.—Sheffield lies on no great lowland route or natural highway. To N.W. and S. the valleys lead only to Pennine dales and lofty moorlands. In 1732, improvements were made in the Don navigation to help the trade of Sheffield and in 1793 the Don was joined to the Trent by the Stainforth and Keadby canal. The original Midland railway main line passed direct from Chesterfield to Rotherham and for more than 40 years Sheffield was reached only by a branch line. The main line through Sheffield was not built until 1870 after the tunnelling of the Sheaf-Rother watershed. Long tunnels connect Sheffield by rail with the west and even now relatively little of the trunk traffic of England passes through the town.

The University of Sheffield began as the Firth college founded by Mark Firth, an eminent steel manufacturer, in 1879. It was enlarged in 1892. Although it provides ample opportunities for a broad cultural education, the university has especially developed branches of study and research related with local

industries, as, *e.g.*, fuel and glass technology, geology and non-ferrous metallurgy. It has also given prominence to dental surgery and pharmacology; and in conjunction with the university of Leeds maintains a laboratory for marine zoology at Robin Hood's Bay. With two new research laboratories for engineering and metallurgy and in its mining department, it is increasingly occupied with research connected with local industries. Like the other universities in manufacturing districts it organises much extramural education amongst persons unable to be regular students of the university. The social interests of the students, both men and women, are well provided for, especially in their respective unions. Within recent years benefactions to an amount over £180,000 have been received. (*See* UNIVERSITIES.) Other educational institutions include the boys' charity school (1706), the free writing school (1715), the girls' charity school (1786), the Wesley college, associated with London university, and Ranmoor college of the Methodist New Connexion.

Sheffield has four voluntary hospitals and it was proposed in 1924 to amalgamate and extend them, utilising the old buildings as receiving wards and casualty stations and carrying on the main work in Norton Hall which was given for the purpose. A new wing of the Royal Infirmary was opened in 1925. In Meersbrook Hall is a fine Ruskin museum, containing Ruskin's art, mineralogical, natural history and botanical collections and some original drawings and valuable books. These are in the custody of the corporation. Part of the manor house of Hallam, dating from the 16th century still remains, and in the south of the city is Broom Hall, a fine old half-timbered building. To the N.W. towards Penistone, is Wharncliffe, retaining many of the characteristics of an ancient forest, and overlooking the valley of the Don from bold rocky terraces and ridges.

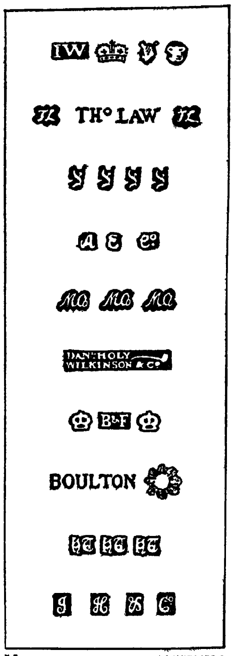
Until 1914, Sheffield was the seat of a suffragan bishop in the diocese of York; at that date it was created a diocese consisting of the archdeaconries of Sheffield and Doncaster with that part of the rural deanery of Dronfield which was within the city boundaries. The old parish church of St. Peter and St. Paul became the cathedral. It is a cruciform building, mainly Perpendicular, built on the site of a Norman edifice which is believed to have been burnt during the wars of Edward III. with the barons. The 14th century tower is the oldest part existing.

The great period of prosperity in the 19th century led to great crowding of population in the valleys and a later spread over the ridges between. The older parts of the town are still irregular and overcrowded, but under the act of 1875 a great number of improvements were effected and have been steadily continued. The latest suburb development is to the west, extending over the moors. The borough was enlarged by the inclusion of part of Tinsley in 1911, and part of Bradfield in 1914, and in 1920 powers were sought to include a large area for purposes of a bold scheme for regional devolution. The area of land incorporated in 1921 included Handsworth and parts of Ecclesfield and Brinsworth, and a new ward of Handsworth was created. The old boards of guardians of Sheffield and Ecclesfield were dissolved in 1925 and a united board established. An exhaustive civic survey has been carried out and a zonal town plan prepared; authority for applying the plan to an area of 5,909 ac. was obtained in 1925. A village with a painted fabrics industry for ex-service men has been established at Coal Aston on the outskirts of the city. In connection with the Derwent valley water scheme, for utilising the water of the Derwent and Ashop rivers, of which 25% will be used by Sheffield, the Howden reservoir was opened in 1912 and the Derwent reservoir and the service reservoir at Ambergate were completed in 1926.

SHEFFIELD, a city of Colbert county, Alabama, U.S.A., on the south bank of the Tennessee river, opposite Florence, in the Muscle Shoals district of the north-western part of the State. It is on Federal highway 72, and is served by the Louisville and Nashville and the Southern railway systems and river steamers. Pop. (1920), 6,682 (29% negroes); 6,221 in 1930 by the Federal census. Sheffield is beautifully situated between the Government nitrate plants No. 1 and No. 2.

SHEFFIELD PLATE is the term applied to articles produced from copper and coated with silver by the process of fusion.

History.—About the year 1742 Thomas Boulsover, a Sheffield cutler, while undertaking repairs to the haft of a knife observed that by the application of heat a piece of silver and the copper to which it accidentally adhered had become fused and could be dealt with as one metal and that the two metals behaved as one when subjected to hammering. This caused him to experiment, with the result that he eventually produced buttons and boxes with a copper foundation coated with silver which had the appearance of being made entirely of the more precious metal. Joseph Hancock, who served his apprenticeship with a relative of the inventor, realized the wider possibilities of the discovery and was the first to apply the process to making saucepans, coffee-pots, candlesticks and other large articles for domestic service, closely resembling in their detail hall-marked silver specimens.



MARKS FROM SPECIMENS OF SHEFFIELD PLATE

These pioneers were soon followed by other cutlers who added the production of Sheffield Plate to their other undertakings. Two factors were necessary for the complete success of the new invention, viz., capital and skilled labour. The money required was readily obtained locally, but the highly trained assistance of London silversmiths was also essential and ultimately when their services were enlisted the success of the undertaking was assured.

The excellent appearance and relative cheapness of these plated productions caused a widespread demand. Henry Tudor (*see* Plate, fig. 3), a local gentleman, having realized the great possibilities of the invention, appears to have been the first to seek the assistance of a London silversmith, and about the year 1760 entered into partnership with Thomas Leader, and as Tudor and Leader they founded the first Sheffield plate and silver manufactory on an extensive scale. Boulsover apparently did not embark on this new phase of the industry, but turned to the rolling of metals, still however, carrying on his lucrative plated button manufactory.

Hancock appears to have carried on the making of Sheffield Plate from about the year 1750 until 1765. He then interested himself chiefly in the production of plated materials required by manufacturers of the finished articles. Originally beaten out into sheets by hand the fused metal was subsequently manipulated by rollers turned by hand; the application of horse and water power followed, and eventually steam was employed to drive the mills.

The establishment of Leader in Sheffield raised the artistic standard of the craft, and from being content at first to copy contemporary London-made silver the Sheffield Plate workers soon evolved a style of their own and found much inspiration in the work of the brothers Adam and John Flaxman, particularly in the construction of candlesticks. So cunningly devised were some of their productions and so peculiarly marked (Plate I., figs. 3–10) that in the year 1773, the London silversmiths were successful in obtaining an injunction restraining the Sheffield plate makers from using marks on their wares.

Prominent amongst men of local origin who assisted in the advancement of design and workmanship in this new craft, and who themselves built up lucrative businesses, were John Winter (Plate I., fig. 9), Thomas Law (Plate I., fig. 2), Richard Morton and Joseph Ashforth, whose marks are still to be found on Old Sheffield Plate made previous to 1773.

By the year 1784, after much agitation the Sheffield platers were authorized to use marks once again, but it was enacted that such marks should bear the name of the maker together with a distinctive device not used for silver. About the year 1790 the most prominent manufacturers and designers were Samuel

12. Entrée dish and warmer with oak leaf shell and gadroon mount by Watson & Bradbury, 1812

Roberts, Nathaniel Smith, Daniel Holy, the Watsons, Bradburys and Creswicks. Birmingham played but a small part in the earlier history of the trade, being represented practically by one man, Matthew Boulton. Though his workmanship, in association with his partner John Fothergill, is excellent and dates from the period 1760, he had many other interests, and articles made by him from fused plate of the first period are somewhat scarce. In the early part of the 19th century he and his successors carried on an increasing business, and their device, the sun, is still to be found on many old Sheffield specimens.

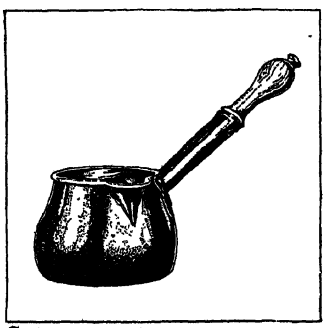
WORKSHOP IN AN 18TH CENTURY SHEFFIELD PLATE FACTORY SHOWING PROCESS OF PLATING BY FUSION

The manufacture of fused plate, though confined in England to Sheffield and Birmingham for many years, spread in the early part of the 19th century to the continent of Europe, but the articles made in France, Russia and Central Europe never bore comparison in quality or craftsmanship with those of the Sheffield makers.

Processes.—To produce the plated metal sheets, ingots of copper containing a slight alloy, $1\frac{1}{2}''$ to $1\frac{1}{4}''$ thick by $2\frac{1}{2}''$ wide by $8''$ long, were cast, and the surfaces planed, then smoothed. A sheet of silver was cut to the size of the face of the ingot, about $\frac{1}{8}''$ thick, also smoothed on the surfaces. The two prepared surfaces were cleaned of all impurities, placed together and firmly pressed. A copper plate dressed with solution of chalk was placed upon the silver and all three firmly secured together, and bound with iron wire.

The ingot was now placed in a furnace especially prepared, and most carefully watched until the silver melted slightly when it firmly adhered to the copper surface. After being withdrawn from the oven and allowed to cool, the copper plate and iron wires were removed from the ingot which after being well cleaned and trimmed was ready for the rolling mills.

At first plated on one side only, a new process was discovered about the year 1765 which enabled the makers to produce sheets with a coating of silver on both sides of the metal. The ingenious craftsmen were now not far off realizing their ambition, viz., to produce articles that were indistinguishable from those made in London of standard silver.



SAUCEPAN OF ABOUT 1755, MARKED JOSEPH HANCOCK, SHEFFIELD

Plated Wire.—About the year 1768, plated wire was introduced. A strip of fine silver $\frac{1}{32}''$ thick was bent to fit a round copper rod $5''$ long by $1''$ diameter. The two metals were then united by fusion and afterwards drawn continuously through a "whortle" until they assumed the form of a wire. The repeated drawings brought the two silver edges together almost as one piece. This early method was improved upon and superseded some years later, though the original principle was adhered to in its general details.

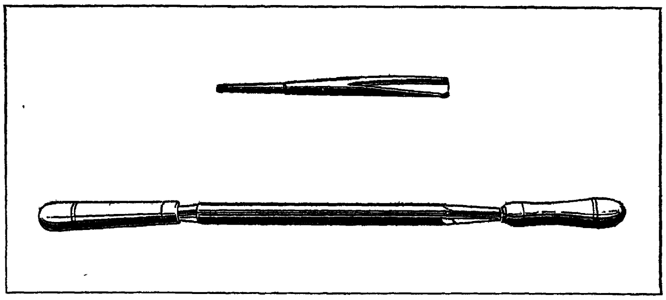
Silver Edges.—The next feature that marked a great advance in manufacture was the addition of silver edges, invented by George Cadman in 1788. Previous to this the raw copper edges had been hidden with solder. The method consisted of drawing a hollow silver wire through a hole which corresponded in size exactly with the edges of the article it was intended to cover: at the same time this process shaped up the silver thread to a groove, thereby enabling the operation of soldering on these silver edges to be carried out more easily.

Silver Shields for Engraving.—The method of rubbing in silver shields by applied heat was evolved about the year 1810. Previous to this in order to carry out the engraving of crests, etc., it had been necessary to solder in extra heavily plated sections of metal.

This invention has been attributed to a man of the name of Wilks, who also improved the method of production of plated wire. Having hammered the surface on to which the shield was to be fixed, a piece of pure silver was cut suitable to the size of article to which it was to be made to adhere and heated lightly in a flame, it was flattened all over and chamfered on the edges, as thinly as possible. After being cleaned of impurities the shield was secured to the centre of the plate and heated till it adhered to the metal, then quickly rubbed with a burnish until it was definitely sealed to the under surface. The blank was subsequently hammered until both silver shield and fused plated sheet were brought to one level.

With all these discoveries and inventions allied to their skill in technique and design, it is not surprising that early in the 19th century the Sheffield platers then at the height of their prosperity led the fashion in production of domestic silver as well as Sheffield Plate. By the aid of steel dies in which the delicate tracery of their conceptions could be stamped, they continued to produce on an elaborate scale new designs with which the London silversmiths found it difficult to compete.

End of the Industry.—Having for close on a century held the field for pre-eminence in design and workmanship, Sheffield Plate was gradually superseded by articles plated by the process of electro disposition; though even as late as the 1851 Exhibition the reports of the jurors were unfavourable to this new invention. "They desired to guard against being considered as expressing an opinion on the merit of the application of the electro process of silverplating to objects of domestic use."



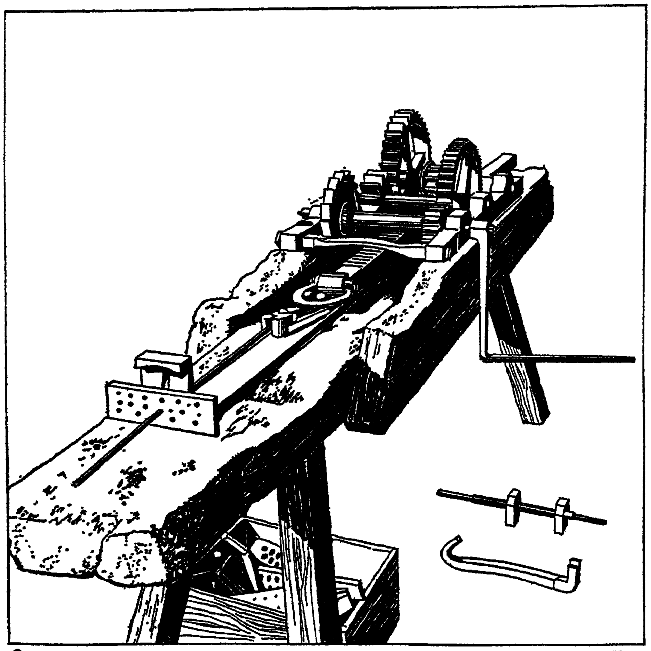
ABOVE: SECTION OF METAL BEFORE BEING DRAWN INTO WIRE; AND, BELOW: OLD BURNISHER USED IN FINISHING PLATED WIRE

By the year 1860 the firms in Sheffield which had declined to adapt themselves to this innovation were gradually dying out. Though the two processes had merged into each other gradually by the year 1865, the older method of plating by fusion for articles of domestic use had ceased to exist. The production of fused plated silver is still carried on for the making of buttons, it having been found that the rolling and hammering of the sheets is conducive of greater lasting properties for articles so continuously subjected to hard wear.

Old Sheffield Plate.—About 30 years after its disappearance as a commercial commodity, the acquisition of what was by then termed "Old Sheffield Plate" became a cult amongst collectors of antiques. It was evident that the process of manufacture might be classed as a lost art. The superb workmanship could not be disputed and was well nigh impossible of reproduction. Most of the older skilled craftsmen had by then passed away, and the younger ones had adopted other callings. The demand soon began greatly to exceed the supply. This state of affairs was

followed by the appearance on the market of many imitations electro-plated on copper, which were dishonestly described as "Sheffield Plate." To so great an extent were these spurious articles sold as Sheffield plate that in the year 1911 prosecutions were undertaken by the Sheffield Cutlers company, when it was established in court that the term "Sheffield Plate" could only legally be applied to articles made by the older method of plating by fusion.

The tendency to-day has not been towards a general increase in values of all specimens of Old Sheffield Plate, but those of



OLD DRAW BENCH APPLIANCES FOR MAKING AND DRAWING WIRE. THE TWO INSTRUMENTS ON THE RIGHT COMPRISE THE "MAUNDRILL"

utility such as candlesticks, candelabra, waiters, trays, entrée dishes, tea services, salt cellars and mustard pots, coffee pots, and many original designs in pierced work have advanced greatly in value. For such articles in perfect condition almost as high a figure is occasionally paid as for contemporary hall-marked silver specimens.

With regard to the large articles that, early in the 19th century, were so prominently displayed on sideboards and dining tables, these, under modern conditions of home life, are not now greatly in request, consequently they may frequently be purchased at a price which is under their original cost.

With regard to the future of the industry, the modern demands for a cheaper class of goods has led to a deterioration of design generally associated with mass production. Possibly silver plated articles may eventually be superseded for domestic use by solid silver, which since the removal of duty in 1891 and decline in value of the raw metal has greatly grown in demand. Again, too, there has been a resuscitation of pewter for table use, which is treated more scientifically than formerly and bears a marked resemblance to a standard silver. Pewter also has the advantage of practical immunity from tarnish, whilst the material is easily worked and very durable.

The manufacturers of best quality plated goods are to-day more concerned with the production of wares suitable for hotels, restaurants, clubs and the shipping services, than for domestic utility. *See* SILVERSMITHS' AND GOLDSMITHS' WORK.

(F. BRA.)

SHEIKH or **SHAYKH,** an Arabic title of respect. Strictly it means a venerable man, of more than 50 years of age. It is specially borne by heads of religious orders, chiefs of tribes and headmen of villages. Every village, however small, every separate quarter of a town, has a sheikh in whom is lodged the executive power of government—a power loosely defined, and of more or less extent according to the personal character and means of the individual who wields it. (For the Sheikh ul-Islam *see* MUFTI.)

SHEKEL, originally a Jewish unit of weight ($\frac{1}{50}$ of a mina, and $\frac{1}{3000}$ of a talent) and afterwards a coin of the same weight (Heb. *shakal,* to weigh). The Biblical references to shekels must refer to uncoined ingots. In the time of Josephus it seems that the *light* shekel weighed from 210 to 210·55 grains; the *heavy* shekel was twice that amount, corresponding to 1s. 4½d. and 2s. 9d. respectively in English silver. Jewish shekels were first coined by Simon the Hasmonean, probably in 139–138 B.C. These bear inscriptions in the archaic Hebrew and various emblems, such as the cup or chalice, the lily branch with three flowers, the candlestick, the citron and palm branch and so forth. They never bear the portraits of rulers or figures of animals. A later series of shekels, belonging to the Roman period, are tetradrachms, "which came from the mints of Caesarea and Antioch and were used as blanks on which to impress Jewish types." Hence in Matt. xvi. 24 the temple tax of half a shekel is called a didrachm (2 drams). In 2 Samuel xiv. 26 we read of "shekels after the King's weight." The Hebrews divided the shekel into 20 parts, each of which was called a *gerah.* (*See* also NUMISMATICS.)

See articles in *Ency. Bibl.* col. 4,442, and Hastings' *Dict. of the Bible,* ii. 417 *seq.;* F. W. Madden, *Coins of the Jews* (1881); T. Reinach, *Jewish Coins* (1903).

SHEKINAH, a Hebrew word meaning "that which dwells," or "the dwelling." An expression used in the Targums in place of "God." The word "Shekinah" is of constant occurrence in the Targums (*q.v.*). Great care was taken by the scribes to mitigate the anthropomorphic expressions applied to God in the Scriptures, and, by paraphrase, to prevent such expressions from giving rise to erroneous views in the popular mind as to God's personal manifestation. Thus, whenever any indication of local limitation or action of God was implied or expressed, in the Hebrew text, the Targumists were careful to substitute some expression involving the use of "Shekinah." Thus Ex. xxix. 45 is rendered in the Targum (Onkelos): "And I will cause my Shekinah to dwell," etc. All expressions implying God's *local* presence are similarly rendered: *e.g.,* Habak. ii. 20 "Jehovah was pleased to cause His Shekinah to dwell." "To see" God is similarly paraphrased. Thus Is. xxxiii. 17 is rendered "Thine eyes shall see the Shekinah of the king of the worlds." So "hiding the face," when used of God is regularly paraphrased "remove His Shekinah" (Is. lvii. 17, viii. 17, lix. 2). Closely connected with the idea of the Shekinah is that of "the glory of the Lord." "Glory," indeed, in this connection was conceived of as a property of the Shekinah (as, in fact, it is of God). For the divine "glory" as a property of the Shekinah, *cf., e.g.,* Is. vi. 5 which is rendered "mine eyes have seen the glory of the Shekinah of the King," etc.

This Shekinah-glory is several times denoted in the New Testament by δόξα. The most notable passage is Rom. ix. 4, where St. Paul, enumerating the list of Israel's privileges, says: "whose is the adoption, *and the glory*" (*i.e.,* the Shekinah-glory); *cf.,* Luke ii. 9. There is also an obvious allusion to the Shekinah in the description of the theophanic cloud of the transfiguration-narrative (St. Matt. xvii. 5 and parallels) the same verb being used as in the lxx. of Exod. xl. 34, *seq.* There can be no doubt too, that the word rendered "tabernacle" (σκηνή) with the corresponding verb "to tabernacle" (σκηνοῦν) is used in St. John i. 14, and Rev. xii. 3, because of its likeness to the term "Shekinah." In St. John i. 14, there is an allusion to the Word (the *mēmrā* of the Targums) the Shekinah, and the Shekinah-glory, all of which the writer declares became incarnate in Jesus. *Cf.* also Heb. i. 3.

It is remarkable that the *mēmrā* (Logos or "Word") of the Targums almost entirely disappears in the Midrashic literature and the Talmud, its place being taken by Shekinah. The Rabbis apparently dreaded the possibility of such terms becoming hypostasized into personal entities distinct from God. Against this they emphasized the Shekinah-idea. It is safe to say that wherever Shekinah is mentioned in Rabbinic literature it is God's direct action or activity that is thought of. Independent personality is never imputed to it. (Maimonides, however, regarded the Shekinah, like the *mēmrā* and "the glory" as a distinct entity.) It is probable that the use of the term was often in Rabbinic

writings polemical (against Jewish Christians or gnostic sects).

SHELBY, a city of North Carolina, U.S.A., the county seat of Cleveland county; in the foothills of the Blue Ridge. Pop. 10,789 in 1930 (Federal census). Mineral springs and the natural beauty of the region have made the city a health and pleasure resort, and since 1900 it has been developing rapidly as an industrial centre. Its textile mills had 76,000 spindles in 1928. The city was founded and incorporated in 1844.

SHELBYVILLE, a city of Indiana, U.S.A., 27 m. S.E. of Indianapolis, on the Blue river; county seat of Shelby county. It is served by the Big Four and the Pennsylvania railways. Pop. 10,618 in 1930. It was named after General Isaac Shelby of Kentucky, was platted in 1822, incorporated as a town in 1850, and chartered as a city in 1860.

SHELDON, GILBERT (1598–1677), archbishop of Canterbury, was born at Stanton in the parish of Ellastone, Staffordshire, and educated at Oxford. He was ordained in 1622 and was appointed chaplain to Thomas Lord Coventry (1578–1640). Four years later he was elected warden of All Souls college, Oxford. In 1648 he was ejected from All Souls by order of parliament for his royalist activities, and imprisoned for some months, but he regained the wardenship in 1659. In 1660 he became bishop of London and master of the Savoy, and the Savoy Conference was held at his lodgings. He was consecrated archbishop of Canterbury in 1663. He was greatly interested in the welfare of Oxford University, of which he became chancellor in 1667, succeeding Clarendon (1609–74). The Sheldonian theatre at Oxford was built (1669) and endowed at his expense.

SHELDRAKE or **SHELD-DRAKE** (*Tadorna tadorna*), a bird of the duck tribe, *Anatidae,* distinguished by its size and upright stature, and by its striking black, white, and bay plumage. The head and neck are a very dark glossy green and the speculum, or wing-spot, bronze-green. The bill, which bears a fleshy knob at its base, is pale red. The female is smaller but very similar in coloration. The sheldrake inhabits sandy coasts in Europe, Asia and North Africa, penetrating inland in favourable localities. The nest is made under cover, usually in rabbit-burrows; in the Frisian Islands the people supply artificial burrows to obtain the eggs and down for their own profit. The male assists in incubation and care of the brood.

The allied *T. radjah* of Australia, Papua, and the Moluccas is less brightly coloured, and the head is white. *Casarca rutila,* the ruddy sheldrake, inhabits Barbary, south-eastern Europe and central Asia; it is an almost uniform bay, but with some black and white markings and a green and purple speculum. Other species occur in various parts of Africa and Australia and also in New Zealand.

In 1859, in the London Zoological Gardens, a male *T. cornuta* mated with a female *C. cana* from Africa, the resultant offspring resembling the two Australasian species of *Casarca.*

Related to the sheldrakes are the genera *Chenalopex,* including the Egyptian goose (*C. aegyptiaca*) and *Plectropterus,* the spur-winged goose of Africa.

SHELL, originally a thin flake; the hard outside natural covering of some fruits, seeds and animals (*see* articles on MOLLUSCA; GASTROPODA; MALACOSTRACA, etc.). The word is also used of a hollow projectile filled with explosives (*see* AMMUNITION: *Shell;* ORDNANCE; SHELL-MONEY).

In architecture shell is used for a single dome, considered as a structural entity rather than an architectural form.

SHELLAC: *see* RESINS: *Natural Resins.*

SHELLEY, MARY WOLLSTONECRAFT (1797–1851), English writer, only daughter of William Godwin and his wife Mary Wollstonecraft, and second wife of the poet Percy Bysshe Shelley, was born in London on Aug. 30, 1797. For the history of her girlhood and of her married life *see* GODWIN, WILLIAM, and SHELLEY, PERCY BYSSHE. When she was in Switzerland with Shelley and Byron in 1816 a proposal was made that various members of the party should write a romance or tale dealing with the supernatural. The result of this project was that Mrs. Shelley wrote *Frankenstein,* Byron the beginning of a narrative about a vampyre, and Dr. Polidori, Byron's physician, a tale named *The Vampyre,* the authorship of which used frequently in past years to be attributed to Byron himself.

Frankenstein, published in 1818, when Mary Shelley was at the utmost twenty-one years old, is a very remarkable performance for so young and inexperienced a writer; its main idea is that of the formation and vitalization, by a deep student of the secrets of nature, of an adult man, who, entering the world thus under unnatural conditions, becomes the terror of his species, a half-involuntary criminal, and finally an outcast whose sole resource is self-immolation. This romance was followed by others: *Valperga, or the Life and Adventures of Castruccio, Prince of Lucca* (1823), an historical tale written with a good deal of spirit, and readable enough even now; *The Last Man* (1826), a fiction of the final agonies of human society owing to the universal spread of a pestilence—this is written in a very stilted style, but possesses a particular interest because Adrian is a portrait of Shelley; *The Fortunes of Perkin Warbeck* (1830); *Lodore* (1835), also bearing partly upon Shelley's biography, and *Falkner* (1837). Besides these novels there was the *Journal of a Six Weeks' Tour,* which is published in conjunction with Shelley's prose-writings; and *Rambles in Germany and Italy* in 1840–1842–1843 (which shows an observant spirit, capable of making some true forecasts of the future), and various miscellaneous writings.

After the death of Shelley, Mary in the autumn of 1823 returned to London. At first she had to live by her writings; but after a while Sir Timothy Shelley made her an allowance, which would have been withdrawn if she had persisted in a project of writing a full biography of her husband. In 1838 she edited Shelley's works, supplying the valuable notes. She succeeded, by strenuous exertions, in maintaining her son Percy at Harrow and Cambridge; in 1840 his grandfather acknowledged his responsibilities and in 1844 he succeeded to the baronetcy. She died on Feb. 21, 1851.

See Richard Church, *Mary Shelley* (1928); and bibliography under PERCY BYSSHE SHELLEY.

SHELLEY, PERCY BYSSHE (1792–1822), English poet, was born on Aug. 4, 1792, at Field Place, near Horsham, Sussex. He was the eldest child of Timothy Shelley (1753–1844), M.P. for Shoreham, by his wife Elizabeth, daughter of Charles Pilfold, of Effingham, Surrey. His father was the son and heir of Sir Bysshe Shelley, Bart. (baptized Percy Bysshe; 1731–1815), whose baronetcy (1806) was a reward from the Whig party for political services. Sir Bysshe's father Timothy had emigrated to America, and he himself had been born in Newark, New Jersey; but he came back to England, and did well for himself by marrying successively two heiresses, the first, the mother of Timothy, being his cousin, Mary Catherine, daughter of the Rev. Theobald Michell of Horsham. He was a handsome man of enterprising and ambitious character, accumulated a large fortune, built Castle Goring, and lived in sullen and penurious retirement in his closing years. None of his talent seems to have descended to his son Timothy, who, except for being of a rather oddly self-assertive character, was undistinguishable from the ordinary run of commonplace country squires. The mother of the poet, who was his father's second cousin, is described as beautiful, and a woman of good abilities, but not with any literary turn; she was an agreeable letter-writer. The branch of the Shelley family to which the poet Percy Bysshe belonged traces its pedigree to Henry Shelley, of Worminghurst, Sussex, who died in 1623. These Worminghurst or Castle Goring Shelleys are of the same stock as the Michelgrove Shelleys, who trace up to Sir William Shelley, judge of the common pleas under Henry VII., thence to a member of parliament in 1415, and to the reign of Edward I., or even to the epoch of the Norman Conquest. The Worminghurst branch was a family of credit, but not of special distinction, until its fortunes culminated under the above-named Sir Bysshe.

In the character of Percy Bysshe Shelley three qualities became early manifest, and may be regarded as innate: impressionableness or extreme susceptibility to external and internal impulses of feeling; a lively imagination or erratic fancy, blurring a sound estimate of solid facts; and a resolute repudiation of outer authority or the despotism of custom. These qualities were highly developed in his earliest manhood, were active in his boyhood, and no doubt made some show even on the borderland between childhood and infancy. At the age of six he was sent to a day school at Warnham, kept by the Rev. Mr. Edwards; at ten to Sion House School, Brentford, of which the principal was Dr. Greenlaw, while the pupils were mostly sons of local tradesmen; at twelve (or immediately before that age, on the 29th of July 1804) to Eton. The headmaster of Eton, up to nearly the close of Shelley's sojourn in the school, was Dr. Goodall, a mild disciplinarian; it is therefore a mistake to suppose that Percy (unless during his very brief stay in the lower school) was frequently flagellated by the formidable Dr. Keate, who only became headmaster after Goodall. Shelley was a shy, sensitive, mopish sort of boy from one point of view—from another a very unruly one, having his own notions of justice, independence and mental freedom; by nature gentle, kindly and retiring—under provocation dangerously violent. He resisted the odious fagging system, exerted himself little in the routine of school-learning, and was known both as "Mad Shelley" and as "Shelley the Atheist." Shelley's first published work, a romance entitled "Zastrozzi" (1810), appeared shortly before he left Eton. This volume was followed quickly by "Original Poetry by Victor and Cazire" (1810) written in collaboration with his sister Elizabeth; and another romance "St. Irvyne or the Rosicrucian" (1811). In these early efforts Shelley played the sedulous ape to "Monk" Lewis, Ann Radcliffe, Rosa Matilda and other exponents of the "School of Terror," but worthless though they may be intrinsically, they are not without interest as having been written by the same hand that gave us "Prometheus Unbound," and "Hellas."

Oxford Life.—Shelley entered University College, Oxford, in April 1810, returned thence to Eton, and finally quitted the school at mid-summer, and commenced residence in Oxford in October. Here he met a young Durham man, Thomas Jefferson Hogg, who had preceded him in the university by a couple of months; the two youths at once struck up a warm and intimate friendship. Shelley had at this time a love for chemical experiment, as well as for poetry, philosophy and classical study, and was in all his tastes and bearing an enthusiast. He continued to write verse and published at Oxford a small collection entitled "Posthumous Fragments of Margaret Nicholson" (1810). The title was suggested by Hogg and is the only touch of the burlesque in what otherwise is a feeble attempt at serious poetry. Hogg was not an enthusiast, but he was a steady and well-read classical student. In religious matters both were sceptics; whether Hogg, as the senior and more informed disputant, pioneered Shelley into strict atheism, or whether Shelley, as the more impassioned and unflinching speculator, outran the easy-going jeering Hogg, is a moot point; we incline to the latter opinion. Certain it is that each egged on the other by perpetual disquisition on abstruse subjects, conducted partly for the sake of truth and partly for that of mental exercitation, without on either side any disposition to bow to authority or stop short of extreme conclusions. The upshot of this habit was that Shelley and Hogg, at the close of some five months of happy and uneventful academic life, got expelled from the university. Shelley—for he alone figures as the writer of the "little syllabus," although there can be no doubt that Hogg was his confidant and coadjutor throughout—published anonymously a pamphlet entitled *The Necessity of Atheism* (1811), which he sent round to bishops and all sorts of people as an invitation or challenge to discussion. It amounted to saying that neither reason nor testimony is adequate to establish the existence of a deity, and that nothing short of a personal individual self-revelation of the deity would be sufficient.

The college authorities heard of the pamphlet, identified Shelley as its author, and summoned him before them—"our master, and two or three of the fellows." The pamphlet was produced, and Shelley was required to say whether he had written it or not. The youth declined to answer the question, and was expelled by a written sentence, ready drawn up. Hogg was next summoned, with a result practically the same. The precise details of this transaction have been much controverted; the best evidence is that which appears on the college records, showing that both Hogg and Shelley (Hogg is there named first) were expelled for "contumaciously refusing to answer questions," and for "repeatedly declining to disavow" the authorship. Thus they were dismissed as being mutineers against academic authority, in a case pregnant with the suspicion—not the proof—of atheism; but how the authorities could know beforehand that the two undergraduates would be contumacious and stiff against disavowal, so as to give warrant for written sentences ready drawn up, is nowhere explained. Possibly the sentences were worded without ground assigned, and would only have been produced *in terrorem* had the young men proved more malleable.

Harriet Westbrook.—Shelley and Hogg came up to London, where Shelley was soon left alone, as his friend went to York to study conveyancing. Percy and his incensed father did not at once come to terms, and for a while he had no resource beyond pocket-money saved up by his sisters (four in number altogether) and sent round to him, sometimes by the hand of a singularly pretty school-fellow, Harriet Westbrook, daughter of a retired and moderately rich hotel-keeper. Shelley, in early youth, had a somewhat "priggish" turn for moralizing and argumentation, and a mania for proselytizing; his school-girl sisters, and their little Methodist friend Miss Westbrook, aged between fifteen and sixteen, must all be enlightened and converted to anti-Christianity. He cultivated the society of Harriet, being encouraged in his assiduity by her much older sister Eliza. Harriet fell in love with him; and he, though not it would seem at any time ardently in love with her, dallied along the pathway which leads to sentiment and a definite courtship. This was not his first love-affair; for he had but a very few months before been courting his cousin Harriet Grove, who, alarmed at his heterodoxies, finally broke off with him—to his no small grief and perturbation at the time. It seems that Shelley never indulged in any sensual or dissipated amour; and, as he advances in life, it becomes apparent that, though capable of the passion of love, and unusually prone to regard with much effusion of sentiment women who interested his mind and heart, the mere attraction of a pretty face or an alluring figure left him unenthralled.

After a while Shelley was reconciled to his father, revisited his family in Sussex and made the acquaintance of Miss Elizabeth Hitchener, a school-teacher at Hurstpierpoint with whom, for the space of one year he pursued an intimate and voluminous correspondence. He then stayed with a cousin in Wales, from whence he was recalled to London by Harriet, who wrote complaining of her father's resolve to send her back to her school, in which she was now regarded with repulsion as too apt a pupil of the atheist Shelley. He replied counselling resistance. "She wrote to say" (these are the words of Shelley in a letter to Hogg, dating towards the end of July 1811) "that resistance was useless, but that she would fly with me, and threw herself upon my protection." Shelley returned to London, where he found Harriet agitated and wavering; finally they agreed to elope, travelled in haste to Edinburgh, and there, on Aug. 28, were married with the rites of the Scottish Church. Shelley had by this time openly broken, not only with the dogmas and conventions of Christian religion, but with many of the institutions of Christian polity, and in especial with such as enforce and regulate marriage; he held—with William Godwin—that marriage ought to be simply a voluntary relation between a man and a woman, to be assumed at joint option and terminated at the after-option of either party. If, therefore, he had acted upon his personal conviction of the right, he would never have wedded Harriet, whether by Scotch, English or any other law; but as they were married without delay on their arrival in Edinburgh, it is probable that Harriet may have consented to the elopment on the understanding that Shelley would marry her.

Harriet Shelley was not only beautiful; she was amiable, accommodating, adequately well educated and well bred. She liked

reading, and her reading was not strictly frivolous. But she could not (as Shelley said at a later date) "feel poetry and understand philosophy." She appears to have been a simple-minded affectionate girl who did her best to respond to her husband's somewhat nebulous ideas on sociology and politics. For nearly three years Shelley and she led a shifting sort of life upon an income of £400 a year, one-half of which was allowed (after his first severe indignation at the *mésalliance* was past) by Mr. Timothy Shelley, and the other half by Mr. Westbrook. The couple left Edinburgh for York and the society of Hogg; broke with him upon a charge made by Harriet, and evidently fully believed by Shelley at the time, that, during a temporary absence of his upon business in Sussex, Hogg had tried to seduce her (this quarrel was entirely made up at the end of about a year); moved off to Keswick in Cumberland, where they received kind attentions from Southey, and some hospitality from the duke of Norfolk, who, as chief magnate in the Shoreham region of Sussex, was at pains to reconcile the father and his heir; sailed thence to Dublin, where Shelley was eager in the good cause of Catholic emancipation, conjoined with repeal of the union; crossed to Wales, and lived at Nant-Gwillt, near Rhayader, then at Lynmouth in Devonshire, then at Tanyrallt in Carnarvonshire. All this was between September 1811 and February 1813.

Residence in Wales.—At Lynmouth an Irish servant of Shelley's was sentenced to six months' imprisonment, but released on his master's recognizances, for distributing and posting up printed papers, bearing no printer's name, of an inflammatory or seditious tendency—being a *Declaration of Rights* composed by the youthful reformer, and some verses of his named *The Devil's Walk.* At Tanyrallt Shelley was (according to his own and Harriet's account, confirmed by the evidence of Miss Westbrook, the elder sister, who continued an inmate in most of their homes) attacked on the night of Feb. 26 by an assassin who fired three pistol-shots. It was either a human assassin or (as Shelley once said) "the devil." The motive of the attack was undefined; the fact of its occurrence was generally disbelieved, both at the time and by subsequent inquirers. A disclosure, some years later, proved that a shepherd close to Tanyrallt, named Robin Pant Evan, being irritated by some well-meant acts of Shelley in terminating the lives of dying or diseased sheep, did really combine with two other shepherds to scare the poet, and Evan was the person who played the part of "assassin." This was the break-up of the residence of the Shelleys at Tanyrallt; they revisited Ireland, and then settled for a while in London. Here, in June 1813, Harriet gave birth to her daughter Ianthe Eliza (she married a Mr. Esdaile, and died in 1876). Here also Shelley brought out his first poem of any importance, *Queen Mab;* it was privately printed, as its aggressive tone in matters of religion and morals would not allow of publication. In July the Shelleys took a house at Bracknell near Windsor Forest, where they had congenial neighbours, Mrs. Boinville and her family. Early in the summer of 1814 Shelley paid his last visit to Field Place (during the absence of his father), to see his mother. Several attempts to arrive at a reconciliation with his father had failed, probably owing, among other circumstances, to the officious intervention of the family solicitor.

The Godwin Circle.—The speculative sage whom Shelley especially reverenced was William Godwin (*q.v.*); in 1796 he had married Mary Wollstonecraft, authoress of *The Rights of Woman,* who died shortly after giving birth, on Aug. 30, 1797, to a daughter Mary. With Godwin Shelley had opened a volunteered correspondence at the beginning of 1812, and he had known him personally since the winter which closed 1812. Godwin was then a bookseller, living with his second wife, who had been a Mrs. Clairmont; there were four other members of the household, two of whom call for some mention here—Fanny Wollstonecraft, the daughter of the authoress and Mr. Imlay, and Claire (Clara Mary Jane), the daughter of Mrs. Clairmont. Fanny committed suicide in October 1816, being, according to some accounts which remain unverified, hopelessly in love with Shelley; Claire was closely associated with all his subsequent career. It was towards May 1814 that Shelley first saw Mary Wollstonecraft Godwin as a grown-up girl (she was well on towards seventeen); he instantly fell in love with her, and she with him. Just before this, on March 24, Shelley had remarried Harriet in London, apparently with a view to strengthening his position in his relations with his father as to the family property; but, on becoming enamoured of Mary, he seems to have rapidly made up his mind that Harriet should not stand in the way. She was at Bath while he was in London. They had, however, met again in London and come to some sort of understanding before the final crisis arrived—Harriet remonstrating and indignant, but incapable of effective resistance—Shelley sick of her companionship, and bent upon gratifying his own wishes, which as we have already seen were not at odds with his avowed principles of conduct. For some months past there had been bickerings and misunderstandings between him and Harriet, aggravated by the now detested presence of Miss Westbrook in the house; more than this cannot be said, and it seems dubious whether more will be hereafter known. Shelley, and not he alone, alleged grave misdoing on Harriet's part—perhaps mistakenly. The upshot came on July 28, when Shelley aided Mary to elope from her father's house, Claire Clairmont deciding to accompany them. They crossed to Calais, and proceeded across France into Switzerland. Godwin and his wife were greatly incensed. Though he and Mary Wollstonecraft had entertained and avowed bold opinions regarding the marriage-bond, similar to Shelley's own, and had in their time acted upon these opinions, it is not clearly made out that Mary Godwin had ever been encouraged by paternal influence to think or do the like. Shelley and she chose to act upon their own responsibility—he disregarding any claim which Harriet had upon him, and Mary setting at nought her father's authority. Both were prepared to ignore the law of the land and the rules of society.

The three young people returned to London in September. In the following January 1815 Sir Bysshe Shelley died, and Percy, who had lately been in great money-straits, became the immediate heir to the entailed property inherited by his father Sir Timothy. This entailed property seems to have been worth £6,000 per annum, or little less. He came to an understanding with his father and, giving up certain future advantages, he received henceforth a regular income of £1,000 a year. Out of this he assigned £200 a year to Harriet, who had given birth in November to a son, Charles Bysshe (he died in 1826). Shelley, and Mary as well, were on moderately good terms with Harriet, seeing her from time to time. His peculiar views as to the relations of the sexes appear markedly again in his having (so it is alleged) invited Harriet to return to his and Mary's house as a domicile; an arrangement which did not take effect. He had, undoubtedly, while previously abroad with Mary, invited Harriet to stay in their immediate neighbourhood. Shelley and Mary (who was naturally always called Mrs. Shelley) now settled at Bishopgate, near Windsor Forest; here he produced his first excellent poem, *Alastor, or the Spirit of Solitude,* which was published soon afterwards (1816) with a few others. Thomas Love Peacock was one of his principal associates at Bishopgate.

With Byron in Switzerland.—In May 1816 the Shelleys left England for Switzerland, together with Claire Clairmont, and their own infant son William. They went straight to Sécheron, near Geneva; Byron, whose separation from his wife had just then taken place, arrived there immediately afterwards. A great deal of controversy has arisen as to the motives and incidents of this foreign sojourn. The clear fact is that Claire Clairmont, who had a fine voice and some inclination for the stage, had seen Byron, as connected with the management of Drury Lane theatre, early in the year, and an intrigue had begun between them in London. Prima facie it seems quite reasonable to suppose that she had explained the facts to Shelley or to Mary, or to both, and had induced them to convoy her to the society of Byron abroad; were this finally established as the fact, it would show no inconsistency of conduct, or breach of his own code, on Shelley's part. But documentary evidence shows that Mary was totally ignorant of the amour shortly before they went abroad. Whether or not they knew of it while they and Claire were in daily intercourse with Byron, and housed close by him on the shore of the Lake of Geneva, may be left unargued. The three returned to London in September 1816, Byron remaining abroad; and in January 1817

Claire gave birth to his daughter named Allegra.

The return of the Shelleys was closely followed by two suicides —first that of Fanny Wollstonecraft (already referred to), and second that of Harriet Shelley, who on Nov. 9 drowned herself in the Serpentine. The body was not found until Dec. 10. The latest stages of the lovely and ill-starred Harriet's career have never been very explicitly recorded. It seems that she formed a connexion with some man from whom circumstances or desertion separated her, and that she was treated with harshness by her sister during an illness of their father. She had always had a propensity to the idea of suicide, and she now carried it out in act. Shelley, then at Bath, hurried up to London when he heard of Harriet's death, giving manifest signs of the shock which so terrible a catastrophe had produced on him. So far from Shelley dismissing the subject from his mind it is more than probable that the memory of this tragedy was ever present to him, and especially so during his last days.

This was the time when Shelley began to see a great deal of Leigh Hunt, the poet and essayist, editor of the *Examiner;* they were close friends, and Hunt did something to uphold the reputation of Shelley as a poet—which, we may here say once for all, scarcely obtained any public acceptance or solidity during his brief lifetime. The death of Harriet having removed the only obstacle to a marriage with Mary Godwin, the wedding ensued on Dec. 30, 1816, and the married couple settled down at Great Marlow in Buckinghamshire. Their tranquillity was shortly disturbed by a Chancery suit set in motion by Mr. Westbrook, who asked for the custody of his two grandchildren, on the ground that Shelley had deserted his wife and intended to bring up his offspring in his own atheistic and anti-social opinions. Lord Chancellor Eldon delivered judgment on March 27, 1817. He held that Shelley, having avowed condemnable principles of conduct, and having fashioned his own conduct to correspond, and being likely to inculcate the same principles upon his children, was unfit to have the charge of them. He appointed as their curator Dr. Hume, an orthodox army-physician, who was Shelley's own nominee. The poet had to pay for the maintenance of the children a sum which stood eventually at £120 per annum; if it was at first (as generally stated) £200, that was no more than what he had previously allowed to Harriet. This is the last incident of marked importance in the perturbed career of Shelley; the rest relates to the history of his mind, the poems which he produced and published, and his changes of locality in travelling. The first ensuing poem was *The Revolt of Islam,* referred to near the close of this article.

Removal to Italy.—In March 1818, after an illness which he regarded (rightly or wrongly) as a dangerous pulmonary attack, Shelley, with his wife, their two infants William and Clara, and Claire Clairmont and her baby Allegra, went off to Italy, where the short remainder of his life was passed. Allegra was soon sent on to Venice, to her father, who, ever since parting from Claire in Switzerland, showed a callous and unfeeling determination to see and know no more about her. In 1818 the Shelleys—always nearly with Claire in their company—were in Milan, Leghorn, the Bagni di Lucca, Venice and its neighbourhood, Rome and Naples; in 1819 in Rome, the vicinity of Leghorn and Florence (both their infants were now dead, but a third was born late in 1819, Percy Florence Shelley, who in 1844 inherited the baronetcy and died in 1889); in 1820 in Pisa the Bagni di Pisa (or di San Giuliano), and Leghorn; in 1821 in Pisa and with Byron in Ravenna; in 1822 in Pisa and on the Bay of Spezia, between Lerici and San Terenzio.

The incidents of this period are but few, and of no great importance apart from their bearing upon the poet's writings. In Leghorn he knew Mr. and Mrs. Gisborne, the latter a once intimate friend of Godwin; she taught Shelley Spanish, and he was eager to promote a project for a steamer to be built by her son by a former marriage, the engineer Henry Reveley; it would have been the first steamer to navigate the Gulf of Lyons. In Pisa he formed an intimacy with the Contessina Emilia Viviani, a girl who was pining in a convent pending her father's choice of a husband for her; this impassioned but vague and fanciful attachment —which soon came to an end, as Emilia's character developed less favourably in the eyes of her Platonic adorer—produced the transcendental love-poem of *Epipsychidion* in 1821. In Ravenna the scheme of the quarterly magazine the *Liberal* was concerted by Byron and Shelley, the latter being principally interested in it with a view to benefiting Leigh Hunt by such an association with Byron.

In Pisa Byron and Shelley were constantly together, having in their company at one time or another Shelley's cousin and schoolfellow Captain Thomas Medwin (1788–1869), Lieutenant Edward Elliker Williams (1793–1822) and his wife, to both of whom the poet was very warmly attached, and Captain Edward John Trelawny, the adventurous and romantic seaman, who has left important and interesting reminiscences of this period. Byron admired very highly the generous, unworldly and enthusiastic character of Shelley, and set some value on his writings; Shelley half-worshipped Byron as a poet, and was anxious, but in some conjunctures by no means able, to respect him as a man. In Pisa he knew also Prince Alexander Mavrocordato, one of the pioneers of Grecian insurrection and freedom; the glorious cause fired Shelley, and he wrote the drama of *Hellas* (1821) with its magnificent choruses breathing of hope for the future of mankind.

Last Days.—The last residence of Shelley was the Casa Magni, a bare and exposed dwelling on the Gulf of Spezia. He and his wife, with the Williamses, went there at the end of April 1822 to spend the summer, which proved an arid and scorching one. Peacock describes Shelley as being disillusioned during his last days; there is certainly a trace of melancholy in his later lyrics and correspondence; a foreboding of some approaching fatality which, however, he appears to have attempted to divert. Shelley and Williams, both of them insatiably fond of boating, had a small schooner named the "Don Juan" (or more properly the "Ariel"), built at Genoa after a design which Williams had procured from a naval friend, but the reverse of safe. They received her on May 12, found her rapid and alert, and on July 1 started in her to Leghorn, to meet Leigh Hunt, of whose arrival in Italy he had just been notified. After doing his best to set things going comfortably between Byron and Hunt, Shelley returned on board with Williams on July 8. It was a day of dark, louring, stifling heat. Trelawny took leave of his two friends, and about half-past six in the evening found himself startled from a doze by a frightful turmoil of storm. The "Ariel" had by this time made Via Reggio; she was not to be seen, though other vessels which had sailed about the same time were still discernible. Shelley, Williams and their only companion, a sailor-boy, perished in the squall. The exact nature of the catastrophe was from the first regarded as somewhat disputable. The condition of the "Ariel" when recovered did not favour any assumption that she had capsized in a heavy sea—rather that she had been run down by some other vessel, a felucca or fishing-smack. In the absence of any counter-evidence this would be supposed to have occurred by accident; but a rumour, not strictly verified and certainly not refuted, exists that an aged Italian seaman on his deathbed confessed that he had been one of the crew of the fatal felucca, and that the collision was intentional, as the men had plotted to steal a sum of money supposed to be on the "Don Juan," in charge of Lord Byron. In fact there was a moderate sum there, but Byron had neither embarked nor intended to embark. This may perhaps be the true account of the tragedy; at any rate Trelawny, the best possible authority on the subject, accepted it as true. He it was who laboriously tracked out the shore-washed corpses of Williams and Shelley, and who undertook the burning of them, after the ancient Greek fashion, on the shore near Via Reggio, on Aug. 15 and 16. The great poet's ashes were then collected, and buried in the new Protestant cemetery in Rome. He was, at the date of his untimely death, within a month of completing the thirtieth year of his age.

Character.—The character of Shelley can be considered according to two different standards of estimation. We can estimate the original motive forces in his character; or we can form an opinion of his actions, and thence put a certain construction upon his personal qualities. We will first try the latter method. It cannot be denied that his actions were in some considerable degree abnormal, dangerous to the settled basis of society, and marked

by headstrong and undutiful presumption. But it is remarkable that, even among the censors of his conduct, many persons are none the less impressed by the beauty of his character; and this leads us back to our first point—the original motive forces in that. Here we find enthusiasm, fervour, courage (moral and physical), an unbounded readiness to act upon what he considered right principle, however inconvenient or disastrous the consequences to himself, sweetness and indulgence towards others, extreme generosity (he appears to have given Godwin, though sometimes bitterly opposed to him, between £4,000 and £5,000), and the principle of love for humankind in abundance and superabundance. He respected the truth, as he conceived it, in spiritual or speculative matters, and respected no construction of the truth which came to him recommended by human authority. No man had more hatred or contempt of custom and prescription; no one had a more authentic or vivid sense of universal charity. The same radiant enthusiasm which appeared in his poetry as idealism stamped his speculation with the conception of perfectibility and his character with loving emotion.

In person Shelley was attractive, winning and almost beautiful, but not to be called handsome. His height was nearly 5 ft. 11; he was slim, agile and strong, with something of a stoop; his complexion brilliant, his hair abundant and wavy, dark brown but early beginning to grizzle; the eyes, deep blue in tint, have been termed "stag-eyes"—large, fixed and beaming. His voice was high-pitched and wanting in richness and suavity; his general aspect, though extremely variable according as his mood of mind and his expression shifted, was on the whole youthful. The only portrait of Shelley, from which some idea of his looks used to be formed, is that painted by an amateur, Miss Curran, in 1819; Mrs. Shelley, later, pronounced it to be "in many things very like." This is now in the National Portrait Gallery, together with a quasi-duplicate of it painted by Clint, chiefly from Miss Curran's likeness, and partly from a water colour (now lost) by Lieutenant Williams. In 1905 (*Century Magazine*) another portrait was brought forward: a pencil sketch taken in the last month of the poet's life by an American artist, William E. West, followed by an oil-painting founded on that sketch. The two works differ very considerably, and neither of them resembles Miss Curran's portrait; yet we incline to believe that the sketch was really taken from Shelley.

Place in European Literature.—If we except Goethe (and leave out of count living writers, whose ultimate value cannot at present be assessed), we must consider Shelley to be a supreme poet of the new era which, beginning with the French Revolution, remains continuous into our own day. Victor Hugo shares his lofty poetic stature, and might for certain reasons be even preferred to him; Byron and Wordsworth also belong to the same great period, and later, Tennyson and Browning. The grounds, however, on which Shelley's eminence is based are mainly three. He is unexcelled in his ideality, unexcelled in his music and unexcelled in his importance. By importance we here mean the direct import of the work performed, its controlling power over the reader's thought and feeling, the contagious fire of its white-hot intellectual passion, and the long reverberation of its appeal. Shelley is emphatically the poet of the future. In his own day an alien in the world of mind and invention, and in our day but partially a denizen of it, he appears destined to become, in the long vista of years, an informing presence in the innermost shrine of human thought. Shelley appeared at the time when the sublime frenzies of the French revolutionary movement had exhausted the elasticity of men's thought—at least in England—and had left them flaccid and stolid; but that movement prepared another in which revolution was to assume the milder guise of reform, conquering and to conquer. Shelley was its prophet. As an iconoclast and an idealist he took the only position in which a poet could advantageously work as a reformer. To outrage his contemporaries was the condition of leading his successors to triumph and of personally triumphing in their victories. Shelley had the temper of an innovator and a martyr; he united speculative keenness and humanitarian zeal in a degree for which we might vainly seek his precursor. We have already named ideality as one of his leading excellences. This Shelleian quality combines, as its constituents, sublimity, beauty and the abstract passion for good. Perhaps no outstanding English poet, and he was essentially an English poet, has used a greater variety of forms and measures than Shelley. In the pure lyrics the rapture, the music and the emotion are in exquisite balance, and the work has often as much of delicate simplicity as of fragile and flower-like perfection. Great as Shelley's fame is now, it should be remembered that it was entirely posthumous. He practically received no encouragement during his lifetime, and died believing that the world had rejected his poetry.

Works.—Some of Shelley's principal writings have already been mentioned above; we must now give a brief account of others. *Alastor* (1816) was succeeded (1817) by *The Revolt of Islam*, a poem of no common length in the Spenserian stanza, preaching bloodless revolution; it was written in a sort of friendly competition with Keats (who produced *Endymion*) and is amazingly fine, but as a whole somewhat long-drawn and exhausting. This transcendental epic (for such it may be termed) was at first named *Laon and Cythna, or the Revolution of the Golden City*, and the lovers of the story were then brother and sister as well as lovers—an experiment upon British endurance which the publishers would not connive at. The year 1818 produced *Rosalind and Helen*, a comparatively weak poem, begun in England and finished in Italy, and *Julian and Maddalo*, a very strong one, written in the neighbourhood of Venice—demonstrating in Shelley a singular power of seeing ordinary things with directness, and at once figuring them as reality and transfiguring them into poetry. In each of these two poems Shelley gives a quasi-portraiture of himself; and in the latter one may perhaps trace a veiled description of Harriet's tragic end. The next year, 1819, was his culmination, producing as it did the grand tragedy of *The Cenci* and the sublime ideal drama *Prometheus Unbound*, composed partly on the ruins of the Baths of Caracalla in Rome. This last we have no hesitation in calling his masterpiece. It embodies, in forms of surpassing imagination and beauty, Shelley's deepest and most daring conceptions. Prometheus, the human mind and will, has invested with the powers proper to himself Jupiter, the god of heaven, who thereupon chains and torments Prometheus and oppresses mankind; in other words, the anthropomorphic god of religion is a creation of the human mind, and both the mind of man and man himself are enslaved as long as this god exercises his delegated but now absolute power. Prometheus, who is from of old wedded to Asia, or Nature, protests against and anathematizes the usurper enthroned by himself. At last the anathema (although Prometheus has revoked it by an act of self-conquest) takes effect: Eternity, Demogorgon, dismisses Jupiter to unending nothingness. Prometheus is at once unbound, the human mind is free; he is reunited to his spouse Nature, and the world of man passes from thraldom and its degradation into limitless progression, or (as the phrase goes) perfectibility, moral and material. This we regard as in brief the argument of *Prometheus Unbound*. It is closely analogous to the argument of the juvenile poem *Queen Mab*, but so raised in form and creative touch that, whereas to write *Queen Mab* was only to be an ambitious and ebullient tiro, to invent *Prometheus Unbound* was to be the poet of the future. *The Witch of Atlas* (1820) is the most perfect work among all Shelley's longer poems, though it is neither the deepest nor the most interesting. It may be rated as a pure exercise of roving imagination—guided, however, by an intense sense of beauty, and by its author's exceeding fineness of nature.

The elegy on Keats, *Adonais*, followed in 1821. The translations—chiefly from Homer, Euripides, Calderon and Goethe—date from 1819 to 1822, and testify to the poetic endowment of Shelley not less absolutely than his own original compositions; there are also prose translations from Plato.

Shelley, it will be seen, was not only a prolific but also a versatile poet. Works so various in faculty and in form as *The Revolt of Islam, Julian and Maddalo, The Cenci, Prometheus Unbound, Epipsychidion*, and the grotesque effusions of which *Peter Bell the Third* is the prime example, added to the consummate array of lyrics, have seldom to be credited to a single writer—one, moreover, who died before he was thirty years of age. In prose Shelley

could be as admirable as in poetry. His letters to Thomas Love Peacock and others, and his uncompleted *Defence of Poetry,* are the chief monuments of his mastery in prose; and certainly no more beautiful prose—having much of the spirit and the aroma of poetry, yet without being distorted out of its proper essence—is to be found in the English language.

The chief original authorities for the life of Shelley (apart from his own writings, which contain a good deal of autobiography, if heedfully sifted and collated) are—(1) the notices by Mrs. Shelley interspersed in her edition of the *Poems;* (2) Hogg's amusing, discerning and authentic, although in some respects exaggerated, book; (3) Trelawny's *Records;* (4) the *Life* by Medwin; and (5) the articles written by Peacock. Some other writers, especially Leigh Hunt, might be mentioned, but they come less close to the facts. Among biographical books produced since Shelley's death, by authors who did not know him personally, the leading work is the *Life* by Professor Dowden (2 vols., 1886), which embodies important materials imparted by the Shelley family. *The Real Shelley,* by J. C. Jeaffreson (1885), is controversial in method and decidedly hostile in tendency, and tries a man of genius by tests far from well adapted (in our opinion) to bring out a right result; it contains, however, an ample share of solid information and sharp disquisition. The memoir by W. M. Rossetti, prefixed to an edition of Shelley's *Poems* in two forms of publication (1870 and 1878), was an endeavour to formulate in brief space, out of the then confused and conflicting records, an accurate account of Shelley—admiring, but not uncandidly one-sided. There is valuable material in Lady Shelley's *Shelley Memorials,* and in Dr. Garnett's *Relics of Shelley;* and the memoir by J. Addington Symonds, in the *English Men of Letters* series, is characteristic of the writer. *Shelley in England* by Roger Ingpen contains new facts respecting Shelley's relations with his family, his expulsion from Oxford and some unpublished facts about Harriet's death. One of the handiest editions of Shelley's poems was edited by Thomas Hutchinson (Clarendon Press, 1905), which includes the emendations, &c., published by Mr. C. D. Locock (1903) from examination of the MSS. in the Bodleian Library. Mr. Locock edited in 1911 an excellent and fully annotated edition of the Poems, with some new material. A full edition of Shelley's letters was edited by Roger Ingpen in 1909, reprinted with additions in 1911 and 1916. The most complete collection of Shelley's Poems, Prose works and Correspondence is the *Julian Edition* edited by Roger Ingpen and W. E. Peck (1927–1929). France has by no means neglected Shelley. A. Koszul's *"La Jeunesse de Shelley"* (1910), is a valuable study of the subject, while André Maurois has written a popular romance in his *"Ariel ou la vie de Shelley"* (1923). Mr. Buxton Forman's earlier and excellent edition includes the writings in prose as well as in verse. (W. M. R.; R. I.)

SHELLEY'S CASE, RULE IN, an important decision in the law of real property. The litigation was brought about by the settlement made by Sir William Shelley (*c.* 1480–1549), a judge of the common pleas, of an estate which he had purchased on the dissolution of Sion Monastery. After prolonged argument the celebrated rule was laid down by Lord Chancellor Sir Thomas Bromley, who presided over an assembly of all the judges to hear the case in Easter term 1580–81 (i. Coke's Rep. 93 *b.*). The rule may be stated as follows: When an ancestor by any gift or conveyance takes an estate of freehold and in the same gift or conveyance an estate is limited, either mediately or immediately, to his heirs or the heirs of his body, in such a case the word "heirs" is a word of limitation and the estate of the ancestor is an estate in fee or an estate tail according to circumstances. (*See* also *Van Grutten* v. *Foxwell,* 1897. A.C. 658.) This rule was abolished in England by the Law of Property Act 1925, by which date it had already been abolished in several colonies. It is said to have had its origin in the wish of the law to preserve to the lords their right of wardship. (*See* Burge's *Foreign and Colonial Laws,* vol. iv. pt. II.) In the United States the rule in Shelley's case is in operation as a part of the common law, but it has been repealed by statute in many States.

SHELL-MONEY, a medium of exchange common to many primitive races, consisting of sea shells or pieces of them worked into beads or artificially shaped. Shell-money appears to have been almost universal, being found in America, Asia, Africa and Australia. The shell used by the Indians of Alaska and California was the *Dentalium pretiosum,* a species of tusk-shell. The *ligua,* the highest denomination of their coinage, consisted of twenty-five shells strung together, which from end to end made a total measurement of a fathom (6ft.) or thereabouts, equalling in English coinage about £50.

But the shell most used by primitive peoples has always been the *Cypraea moneta,* or money-cowry (*see* COWRY). It is most abundant in the Indian Ocean, and is collected more particularly in the Maldive Islands, in Ceylon, along the Malabar coast, in Borneo and other East Indian islands, and in various parts of the African coast from Ras Hafun to Mozambique. It was formerly in familiar use in Bengal, where, though it required 3,840 to make a rupee, the annual importation was valued at about £30,000. In western Africa it was, until past the middle of the 19th century, the usual tender. The use of the cowry currency gradually spread inland in Africa, and about 1850 Heinrich Barth found it fairly recognized in Kano, Kuka, Gando and even Timbuktu. In the countries on the coast the shells were fastened together in strings of 40 or 100 each, so that 50 or 20 strings represented a dollar; but in the interior they were laboriously counted one by one. The districts mentioned above received their supply of *kurdi,* as they were called, from the west coast; but the regions to the north of Unyamwezi, where they were in use under the name of *simbi,* were dependent on Muslim traders from Zanzibar. The shell of the land-snail, *Achatina monetaria,* cut into circles with an open centre, has been long used as coin in Benguella, Portuguese West Africa. In parts of Asia *Cypraea annulus,* the ring cowry, was commonly used. In north Australia different shells were used, one tribe's shell being absolutely valueless in the eyes of another tribe. In the islands north of New Guinea the shells are broken into flakes. Two shells are used by these Pacific islanders, one a cowry found on the New Guinea coast, and the other the common pease shell. As late as 1882 local trade in the Solomon Islands was carried on by means of a coinage of shell beads, small shells laboriously ground down to the required size by women.

SHELL-MOUNDS or **KITCHEN-MIDDENS** (Dan. Kjökken-mödding), prehistoric refuse heaps or mounds, found in all quarters of the globe, which consist chiefly of the shells of edible molluscs mixed with fragments of animal bones, and implements of stone, bone and horn. They may sometimes, as in the Straits of Magellan, be seen in process of formation.

Many, of prehistoric origin, have been examined, notably on the eastern coast of Denmark. These were at first thought to be raised beaches, but a cursory examination at once proved their artificial construction. Further investigation proved these shell-mounds to belong to the early part of the Neolithic age (*q.v.*). They contained the remains of quadrupeds, birds and fish, the food of the prehistoric inhabitants. Among the bones were those of the wild bull or aurochs, beaver, seal and great auk, all now extinct or rare in this region. Moreover, shell-mounds contain full sized shells of the common oyster, which cannot live at present in the brackish waters of the Baltic except near its entrance, the inference being that the shores where the oyster at that time flourished were open to the salt sea. Thus also the eatable cockle, mussel and periwinkle abounding in the kitchen-middens are of full ocean size, whereas those now living in the adjoining waters are a third of full size, owing to the want of saltness. This extention of the North sea is called the "Littorina sea"; and it existed round about 4000–3000 B.C., the end of Brooks's Maritime period. The débris is in some places 10ft. to 20ft. thick.

The men of the kitchen-middens had seemingly no knowledge of agriculture, no traces of grain of any sort being found. The only vegetable remains were burnt pieces of wood and some charred substance, possibly a sea-plant used in the production of salt. Flat stones blackened with fire, forming hearths, were also found. That periods of scarcity must have been frequent is indicated by the discovery of bones of the fox, wolf and other carnivora, which would hardly have been eaten from choice. The kitchen-middens of Denmark were not mere summer-quarters; the ancient fishermen appear to have stayed in the neighbourhood

for two-thirds, if not the whole of the year, since by examination of the bones of the wild animals it is often possible to tell the time of year when they were killed. Thus the remains of the wild swan (*Cygnus musicus*), a winter visitor, leaving the Danish coast in March and returning in November, are found in abundance. Additional proof is afforded among the mammalian remains by two periodical phenomena, the shedding of the stag's antlers and the birth and growth of the young. The flint implements found include flakes, axes, awls, sling-stones or net-weights, and rude lance-heads. A fragment of one polished axe was found, at Havelse, which had been worked up into a scraper. Small pieces of coarse pottery are also met with, the typical vessel having a pointed base. The Danish kitchen-midden men were not cannibals. They seem to have resembled the Lapps, small men with heavy over-hanging brows and round heads.

At Omori (Japan), in the Aleutian islands, in British Columbia, Oregon and California shell-mounds were explored, and always proved that the present populations had been preceded by ruder tribes of great antiquity. On the Atlantic coast of Brazil shell-mounds, which must have taken thousands of years to accumulate, are now overgrown with dense forests. Shell-mounds also occur round the coasts of Britain, at Chark near Gosport, inland at Blashenwell farm, Dorset, at Harlyn bay in Cornwall and in Cork harbour, but there is no reason to suppose all these deposits to be contemporary. The shell-mounds on the west coast of Scotland are often associated with raised beaches.

SHELL SHOCK. A term which first arose during the early period of the World War to describe the condition of certain soldiers who had been exposed to unusually heavy bombardment. These persons, in whom a more or less strong hereditary nervous history was obtainable, suffered from various mental and physical disabilities, often of a very severe kind. As time passed the application of the term was extended to cover neurasthenia in its various forms arising under war conditions, and often was so loosely applied that it came to carry a suggestion of deception or malingering and often of lack of courage in the highest degree unjust to the real sufferers. The treatment was psychotherapeutic (*see* Psychotherapy) and usually was highly successful, but in some instances the mental condition of the patient underwent progressive deterioration and ended in insanity. (*See* Neurasthenia; Medicine, General.)

"SHELL" TRANSPORT & TRADING CO., LTD, an oil company founded by the late Viscount Bearsted and his brother Samuel Samuel, M.P. The origin of the title "Shell" is to be found in the fact that these two men, as Eastern merchants, gave special attention to the collection of marine shells, their cleaning, polishing, distribution, and sale for decorative and other purposes. In addition to their normal businesses they carried on a substantial trade in the shipment of Russian and American kerosene, then packed in tins and cases, to the Far East.

Prior to the actual registration of the Shell company M. Samuel & Co. had already established an organisation with various private firms in the East, which proved so successful that a much closer combination was made in 1897 by the formation of the Shell Transport & Trading Co., Limited. From these comparatively small beginnings the business expanded until, in 1928, it covered the production, transport, and distribution of crude petroleum and its products all over the world.

Samuel & Co. acquired in 1895 a considerable territory in Dutch East Borneo and proceeded to exploit it for the production of mineral oil, its refining, shipment, and marketing. This investment was acquired, with other oil investments, by the new company. In the year 1902 negotiations were started with the Royal Dutch company for a reduction of the competition, which was then acute in the Far East, an amicable working arrangement which led to the closest possible amalgamation of interests in 1907. The Royal Dutch company, which had oil concessions in the Dutch East Indies from the Dutch Government, together with the Shell company formed a strong combination that afterwards extended into other areas.

The Shell company in 1928 owned, in conjunction with their associates the Royal Dutch company, oil lands in the Dutch East Indies, Sarawak, Egypt, Rumania, Mexico, Venezuela, Trinidad, the United States, Argentine, etc. Starting with three tank steamers of about 4,500 tons capacity each (which were constructed for transporting general cargo on the return voyages from the Far East), the tonnage owned by the company in 1928 exceeded 1,000,000 tons. From an initial capital of £1,800,000, the authorised Shell capital in 1928 had risen to £43,000,000, the issued capital being over £26,500,000 valued in the open market at close on £100,000,000. (L. C. M.)

SHELTON, THOMAS (*fl.* 1612–1620), English translator of *Don Quixote.* In the dedication of *The delightful history of the wittie knight, Don Quishote* (1612–20) he explains to his patron, Lord Howard de Walden, afterwards 2nd Earl of Suffolk, that he had translated *Don Quixote* from Spanish into English some five or six years previously in the period of forty days for a "very dear friend" who was unable to understand the original. Shelton did not use the original edition of Cervantes, but one published in Brussels in 1607. On the appearance of the Brussels imprint of the second part of *Don Quixote* in 1616, he translated that also into English, completing his task in 1620, and printing at the same time a revised edition of the first part. His performance has become a classic among English translations for its racy, spirited rendering of the original. It seems safe to identify the translator with the Thomas Shelton who wrote a sonnet prefixed to the *Restitution of Decayed Intelligence* (1605) of Richard Verstegan.

The 1612 edition is available in Fitzmaurice Kelly's reprint for the *Tudor Translations* (1892); that of 1620 is reproduced in Macmillan's "Library of English Classics" with an introduction by A. W. Pollard, who incorporates the suggestions made by A. T. Wright in his *Thomas Shelton, Translator.*

SHELTON, a city of Fairfield county, Connecticut, U.S.A., on the west bank of the Housatonic river, opposite Derby and Ansonia; served by the New York, New Haven and Hartford railroad. Pop. (1920), 9,475 (30% foreign-born white); it was 10,113 in 1930. Shelton (formerly Huntington) was incorporated in 1789, and the city was chartered in 1917.

SHEM was the eldest of Noah's three sons. In the Old Testament genealogical tables tracing the origins and connections of the various peoples we find among the descendants of Shem, in addition to the Hebrews, Elam, Assyria, Aram, Lud. From the name is derived the adjective Semitic (*see* Semitic Languages). The interesting statement in Genesis ix. 26 that Yahweh was "the God of Shem" suggests, what is indeed on other grounds probable, that Yahweh was worshipped by peoples akin to the Hebrews. Roughly speaking, the nations supposed to have descended from Shem lie geographically between the descendants of Japheth on the North, and those of Ham on the South. *See* also Ham, Japheth.

SHEMAKHA, a town of Russia in the Azerbaijan S.S.R., in 40° 38′ N., 48° 37′ E. The population has declined from 20,000 to 3,631 (1926) owing to the terrible times following the 1917 revolution. Shemakha was the capital of the khanate of Shirvan, and was known to the Roman geographer Ptolemy as Kamachia. About the middle of the 16th century it was the seat of an English commercial factory, under the traveller Jenkinson, afterwards envoy-extraordinary of the khan of Shirvan to Ivan the Terrible of Russia. In 1742 Shemakha was taken and destroyed by Nadir Shah of Persia, who, to punish the inhabitants for their creed (Sunnite Mohammedanism), built a new town under the same name about 16 m. to the west at the foot of the main chain of the Caucasus. The new Shemakha was at different times a residence of the khan of Shirvan, but was finally abandoned, and

the old town rebuilt. The Russians first entered Shirvan in 1723, but soon retired. In 1795 they captured Shemakha as well as Baku; but the conquest was once more abandoned, and Shirvan was not finally annexed to Russia until 1805.

SHENANDOAH (shĕn′-ạn-dō′ạ), an anthracite-mining borough of Schuylkill county, Pennsylvania, U.S.A., 35 m. S.W. of Wilkes-Barre; served by the Lehigh Valley, the Pennsylvania and the Reading railways. Pop. (1920), 24,726 (31% foreign-born white); 21,782 in 1930 by Federal census. It is an important mining and shipping centre in the Schuylkill region of the great anthracite fields. A log house was built here in 1835, but no further development took place until 1862, when the first colliery was opened. The borough was incorporated in 1866.

SHENANDOAH VALLEY, in Virginia, U.S.A., begins at the Potomac river and extends south-westward between the Blue Ridge mountains on the east and the Alleghenies on the west, to the eminence of land between Staunton and Lexington. The valley is more than 100 m. long and varies in width from 20 to 30 m.; included within its area are Berkeley and Jefferson counties, W. Va., and Frederick, Clarke, Warren, Shenandoah, Page, Rockingham and Augusta counties, Va. Located within this region are a score of thriving towns and cities, the most populous of which are Staunton, Winchester, Waynesboro, Woodstock, Ft. Royal, Luray and Berryville. The chief stream of the valley is the Shenandoah river which unites with the Potomac in the picturesque water gap at Harper's Ferry.

Agriculture, stock-raising and flour-milling have long been important industries of the region; in the lower valley are numerous orchards of apples and peaches. In recent years dairy farming, the breeding of fine live stock and poultry farming have assumed large proportions. The rugged water gap at Harper's Ferry, the wooded hills and numerous grottoes and limestone caverns make the Shenandoah valley attractive for tourists.

The first white man to visit the valley was Louis Michelle, a Frenchman, in 1707; he was followed in 1716 by Governor Spotswood and his Knights of the Horseshoe. The first settlers to enter the region were Germans and Scottish-Irish who came in from Pennsylvania in the early 1730s. During the Civil War the valley was the scene of many bloody battles, especially those in which "Stonewall" Jackson participated.

See *History of the Lower Shenandoah Valley* (1890), ed., J. E. Norris; and J. W. Wayland, *A Bird's-Eye View of the Shenandoah Valley* (1924). (X.)

SHENANDOAH VALLEY CAMPAIGNS

In the American Civil War (1861–65) the Shenandoah Valley was often the scene of military operations; at two points in the war these operations rose to the height of separate campaigns possessing great significance in the general development of the war. From a military point of view the Shenandoah Valley was valuable to the army which controlled it as a requisitioning area, for in this fertile region crops and cattle were plentiful. There were, moreover, numerous mills and factories. For the Confederates the Valley was also a recruiting area. A macadamized road from Lexington via Staunton and Winchester to Martinsburg gave them easy access to Maryland and enabled them to cover Lynchburg from the north. By a system of railways which united at Gordonsville and Charlottesville troops from Richmond and Lynchburg were detrained within easy distance of five good passes over Blue Ridge, and as Strasburg in the Valley lies almost due west of Washington it was believed in the North that a Confederate army thereabouts menaced a city the protection of which was a constant factor in the Federal plan of campaign.

In the spring of 1862 the immense army organized by Gen. McClellan advanced and threatened to sweep all before it. The Confederates, based on Richmond, were compelled to show a front westward to the Alleghanies, northward to the Potomac and eastward to the Atlantic. The main armies were engaged on the Yorktown peninsula and the other operations were secondary. Yet in one instance a Confederate detachment that varied in strength between 5,000 and 17,000 contrived to make some stir in the world and won renown for its commander. Gen. Thomas J. Jackson with small means achieved great influence on the course of the war in the main theatre. The Valley operations in 1862 began by a retrograde movement on the part of the Confederates, for Jackson on March 12 retired from Winchester, and Banks at the head of 20,000 men took possession. Banks pushed a strong detachment under Shields on to Strasburg a week later, and Jackson then withdrew his small division (5,000) to Mt. Jackson. Banks, however, recalled Shields in accordance with orders from Washington, Jackson conceived that he was bound to follow Shields, and, when Shields stood at bay at Kernstown on March 23, with 7,000 men, Jackson at the head of 3,500 attacked and was badly beaten.

The proof thus afforded by Jackson of his inability to contend with Shields seems to have been regarded by the Federal authorities as an excuse for reversing their plans; Shields was reinforced by Williams's division, and with this force Banks undertook to drive Jackson from the Valley. A week after the battle of Kernstown, Banks moved to Strasburg with 16,000 men, and a month later (April 29) was at Newmarket, after much skirmishing with Jackson's rear-guard which burnt the bridges in retiring. Meanwhile Jackson had taken refuge in the passes of Blue Ridge, where he too was reinforced. Ewell's division joined him at Swift Run Gap, and at the beginning of May he decided to watch Banks with Ewell's division and to proceed himself with the remainder of his command to join Edward Johnson's brigade, then beset by Gen. Milroy west of Staunton. Secretly moving by rail through Rockfish Gap, Jackson united with Johnson and in a few days located Milroy at the village of McDowell. After reconnaissance Jackson concentrated his forces on Setlington Hill and proposed to attack on the morrow (May 8), but on this occasion the Federals (Milroy having just been joined by Schenck) took the initiative, and after a four hours' battle Jackson was able to claim his first victory. The Confederates lost 500 out of 6,000 men and the Federals 250 out of 2,500 men.

Meanwhile the army under Banks, now at Strasburg, had been largely sent elsewhere. Jackson's opportunity had come to destroy Banks's force completely. The Confederates numbered 16,000, the Federals only 6,000 men. Jackson availed himself of the Luray Valley route on the eastern or "blind" side of the Massanutton range to surprise the post at Front Royal as a preliminary to falling upon Banks. He captured the post, but failed to intercept Banks who escaped northwards by the turnpike road and covered his retreat across the Potomac by a rear-guard action at Winchester on May 25. On May 31 Frémont had reached Cedar Creek. McDowell was at Front Royal and Jackson had retired to Strasburg, where he was compelled to wait for a detachment to come in. This rejoined on the evening of June 1.

Ewell's division held Frémont back until Jackson was on his way to Newmarket. McDowell had sent Shields up the Valley by the Luray route. But Jackson gained Newmarket in safety and destroyed the bridge up to Port Republic by which Shields could emerge from the Luray Valley to join Frémont, who was left to cope with Jackson single-handed. Jackson's rear-guard impeded Frémont's advance, although a week later (June 7) Frémont at Harrisonburg located his enemy at Cross Keys and next day he attacked with 10,500 men. Shields was still at Luray. Jackson held Frémont with Ewell's division (8,000) and with the remainder moved to the left bank of the Shenandoah near Port Republic to await developments, for Shields had pushed forward a strong advanced guard under Tyler, whose vanguard (two squadrons) crossed the river while Frémont was engaged with Ewell. Tyler's cavalry was driven back with heavy loss. Jackson retained possession of the bridge by which Tyler and Frémont could unite, and next day he crossed the river to attack Tyler's two brigades. The engagement of June 9 is called the battle of Port Republic. Jackson with 13,000 men attacked Tyler with 3,000 men, and Tyler retired with a loss of some 800 men, leaving as many Confederates *hors de combat*.

A few days later Jackson received orders to quit the Valley and join the main army before Richmond, and President Lincoln simultaneously discovered that he could not afford to keep the divisions of Frémont, Banks and McDowell engaged in operations against Jackson; so the Valley was at peace for a time.

In stricter connection with the operations of the main armies in Virginia, the Confederates brought off two great *coups* in the Valley—Jackson's capture of Harper's Ferry and Martinsburg in the autumn of 1862 and Ewell's expulsion of Milroy from Martinsburg and Winchester in June 1863. The concentration of the Federal forces in north Virginia in May 1864 for the campaign which ultimately took Grant and Lee south of the James involved a fresh series of operations in the Valley. At first a Union containing force was placed there under Sigel; this general, however, took the offensive unwisely and was defeated at Newmarket. Next Hunter, who superseded Sigel in command in West Virginia and the Valley, was to co-operate with the Army of the Potomac. Grant detached Sheridan to join Hunter at Charlottesville, but Lee sent Hampton's cavalry by a shorter route to intercept Sheridan, and a battle at Trevillian Station compelled Sheridan to return and leave Hunter to his fate.

Meanwhile on June 13 Early added his command to the Confederate forces in the Valley. Early succeeded in interposing between Hunter and Lynchburg, and within a week drove Hunter out of Virginia by the Kanawha river route. Early then moved down the Valley turnpike unmolested. Expelling Sigel from Martinsburg on July 4, and crossing the Potomac opposite Sharpsburg, he soon appeared before Washington. Early, after creating serious alarm, retired, on July 13, by Leesburg and Snicker's Gap into the Valley at Winchester. Early soon after sent a detachment into Maryland to burn the town of Chambersburg. The alarm in the North for the safety of Washington was only quieted by the appointment of Sheridan to command in the Valley.

Sheridan's Campaign.—He arrived on the scene early in August. His mission was to drive Early up the Valley or, if the Confederates crossed into Maryland, to intercept their return, and in any case he was to destroy all supplies in the country which could not be consumed by his own army. Sheridan made Harper's Ferry his headquarters and concentrated at Halltown. Early retained his position about Bunker Hill, destroyed the Ohio railroad, and held the main road up the Valley until Sheridan moved out in force on Aug. 10. Early then retreated up the Valley to Fisher's Hill (Strasburg), where he expected to be

joined by Anderson's corps from Richmond. Sheridan had followed Early, but hearing of this reinforcement to the enemy, he decided to take up a defensive line at Halltown—the only point in the Valley which did not favour flanking operations—and await the arrival of adequate reinforcements. For a month the two armies had manoeuvred between Halltown and Strasburg, each commander hoping for such an increase to his own or decrease of his enemy's numbers as would justify attack. The Valley operations were aided indirectly by assaults and sorties about Petersburg. Grant aimed at preventing Lee sending reinforcements to Early until Sheridan's plans had been carried out. Meanwhile Early had been gathering up the harvests in the lower Valley, but on Aug. 20 Sheridan was able to report "I have destroyed everything that was eatable south of Winchester, and they will have to haul supplies from well up to Staunton." Sheridan in September could put 23,000 infantry and 8,000 cavalry into action, and at this moment he was visited by Grant, who encouraged his subordinate to seize an opportunity to attack the enemy.

The first encounter of Sheridan and Early took place on Sept. 19, about 2m. east of Winchester. Sheridan had crossed the Opequan and found the enemy in position astride the Winchester-Berryville road. Early was outnumbered and outfought, but he attributed his defeat to the enemy's "immense superiority in cavalry," and in fact Sheridan depicts Merritt's division as charging with sabre or pistol in hand and literally riding down a hostile battery, taking 1,200 prisoners. Early then retreated through Strasburg, but at Fisher's Hill behind Tumbling Run, where the Valley was entrenched on a front of 3m. between the Shenandoah river and Little North mountain, he rallied his forces and again detailed his cavalry to protect his left from a turning movement. But Sheridan repeated his manoeuvre, and again on Sept. 22 Early was attacked and routed, Gen. Crook's column having outflanked him by a détour on the western or Back road. Early now retreated to Mt. Jackson, checked the pursuit at Rode's Hill, and, evading all Sheridan's efforts to bring him again to battle, reached Port Republic on Sept. 25. In the first week of October Sheridan held a line across the Valley from Port Republic along North river to Back road, and his cavalry had advanced to Waynesboro to destroy the railroad bridge there, to drive off cattle, and burn the mills and all forage and breadstuffs. Early had taken refuge in Blue Ridge at Rockfish Gap, where he awaited Rosser's cavalry and Kershaw's division (Longstreet's corps), for Lee had resolved upon again reinforcing the Valley command, and upon their arrival Early advanced to Mt. Crawford and thence to Newmarket. The Federals retired before him, but his cavalry was soon to suffer another repulse, for Rosser and Lomax having followed up Sheridan closely on Oct. 9 with five brigades, the Federal cavalry under Torbert turned upon this body when it reached Tom's brook (Fisher's Hill) and routed it. Sheridan burnt the bridges behind him as he retired on Winchester, and apparently trusted that Early would trouble him no more and then he would rejoin Grant at Petersburg.

Sheridan at Winchester was now free to detach troops to aid Grant, or remain quiescent covering the Ohio railroad, or move east of Blue Ridge. He had resisted the demand of the Government, which Grant had endorsed, that Early should be driven through the Blue Ridge back on Richmond. Sheridan pointed out that guerrilla forces were always in his rear, that he would need to reopen the Alexandria railroad as a line of supply, that he must detach forces to hold the Valley and protect the railroads, and that on nearing Richmond he might be attacked by a column sent out by Lee to aid Early.

Early, however, showed great enterprise in following Sheridan down to Strasburg on Oct. 13 "to thwart his purposes if he should contemplate moving across the Ridge or sending troops to Grant." But as his forward position at Fisher's Hill could not be long maintained for want of forage, he resolved to attack Sheridan, who was in a defensive position along the line of Cedar Creek, and on the night of Oct. 18 he sent three divisions under Gordon to gain the enemy's rear, while Kershaw's division attacked his left and Wharton's division and the artillery engaged him in front. The attack was timed to commence at 5 A.M. on Oct. 19, when Rosser's cavalry was to engage Sheridan's cavalry and that of Lomax was to close the Luray Valley. This somewhat complicated disposition of forces was entirely successful, and Early counted his gains as 1,300 prisoners and 18 guns after routing the Federal corps VIII. and XIX. and causing Wright's corps (VI.) to retire. Yet before nightfall Early's force was in turn routed and he lost 23 guns. Sheridan had been called to Washington to consult Halleck, the "chief of staff," on Oct. 16, in reference to his future movements; for Halleck claimed to control Sheridan and often modified Grant's instructions to his subordinate. Before Sheridan could rejoin his army on Oct. 19 Early had attacked and routed it, but Sheridan met the fugitives and rallied them with the cry: "We must face the other way." He resolved to attack as soon as his troops could be reorganized, but, disturbed by reports of Longstreet's coming by the Front Royal road to cut him off at Winchester, hesitated for some hours; however, at 4 P.M. he attacked and drove back the Confederates and so recovered all the ground lost in the morning, and recaptured his abandoned guns and baggage.

After the battle of Cedar creek, Early again retreated. The Federal Government had agreed to Sheridan's proposal to fortify a defensive line at Kernstown and hold it with a detachment while Sheridan rejoined Grant with the main body. In Feb. 1865 the infantry remaining on each side was less than a strong division. Sheridan seized the opportunity to advance with 10,000 cavalry. Early delayed this advance with his cavalry, while he evacuated Staunton; he called up a brigade to defend Lynchburg and proceeded to Waynesboro to await developments. Sheridan feared to advance on Lynchburg leaving Early on his flank and decided to attack Early at Waynesboro; and on March 2 the Federal commander was rewarded by decisive victory, capturing 1,600 Confederates and their baggage and artillery. Early himself escaped and his cavalry dispersed to their homes in the Valley; all organized resistance in the Shenandoah Valley came to an end.

(G. W. R.)

SHENDI, a town in the Anglo-Egyptian Sudan in the *mudiria* (province) of Berber, on the right bank of the Nile in 18° 1′ N., 33° 59′ E., and 104 m. N.N.W. of Khartum by rail. Shendi possesses small manufactories of leather, iron and cotton; extensive railway workshops and a government experimental farm. It is the headquarters of the cavalry of the Egyptian army stationed in the Sudan. Thirty miles north are the pyramids of Meroë. In 1772 James Bruce stayed some time at Shendi—then governed by a woman—on his way to Egypt after visiting the source of the Blue Nile.

SHENG-KING: *see* MANCHURIA.

SHENSI, the historic province of Chinese civilization centring in the Wei valley, which has afforded a way eastwards from the northern slopes of the mountains of Central Asia via Lanchow-fu and Kungchangfu. Area, 75,270 sq. miles. Pop. estimates vary between six million and 17 million, nine million being a probable total. It is a valley rich in loess, which lends itself to cultivation, and it is protected on the east by a marked narrowing at Tungkwan (*q.v.*). Thus it lent itself to the establishment of a Government which spread its authority in directions north and south, as well as east and west, for Sian, the capital, was the chief city of the empire again and again until the 12th century A.D.

South of the Wei valley the province extends over the Tsinlingshan (*q.v.*) to include the upper Han valley, while to the north the province includes the south part of the high plateau of the Ordos, and is here bounded on the east by the Hwang-ho, where it flows deeply entrenched along a fault zone between the blocks of the Ordos and Shensi. The Great Wall of China follows the northern edge of the Lukwanlingshan across the Ordos plateau, and here marks the limit of the province over against the desert. The Ordos, including North Shensi, is a portion, geologically, of the Sinian mole, that is, of an ancient block now broken into sections, enclosed on the north-west, north and east by the Hwang-ho, which, in the north, runs just beneath one of the mountain-arcs bordering the Mongolian plateau, as they border the whole highland of Central Asia.

The climate north of the Tsinlingshan is characterized by long dry cold, with winds blowing out from the interior of Asia, and much dust, while in summer the rain supply may be very small. The climate south of the range, on the other hand, grades towards that of Szechwan, but is colder than the latter. The valleys of the Wei and Han are rich agriculturally, with wheat, cotton, and even rice in the Wei. Wheat is by far the largest crop. Peas, maize, millet, barley and fruits are grown. The cotton grown in many places is a variety of Tarim ancestry, which suits the native looms, and so has not been displaced by the American variety, which, however, grows better in Shensi than elsewhere in China. Cotton is often sown in April, on the opening of the rainy season, and harvesting occurs in later summer; the crop is 800,000–1,000,000 piculs per annum, and while the native cotton is used at home, the crop of the American variety is mostly sent to Tientsin for sale. There are several factories working cotton in Sian and a few with other industries, while some factories occur here and there in other parts of the province. Coal is mined at Hanchenghsien. Oil is mined farther north, near the Yen. Sian is the capital and Hanchungfu the chief city of the south.

See F. von Richthofen, *China*, vol. ii. (1882); L. Richard, *Géographie de l'Empire de Chine* (1905).

SHENSTONE, WILLIAM (1714–1763), English poet, son of Thomas Shenstone and Anne, daughter of William Penn of Harborough Hall, Hagley, was born at the Leasowes, a property in the parish of Halesowen, now in Worcestershire, but then included in the county of Shropshire. At school he began a lifelong friendship with Richard Jago, and at Pembroke College, Oxford, where he matriculated in 1732, he made another firm friend in Richard Graves, the author of *The Spiritual Quixote*. In 1742 he published anonymously a revised form of *The Schoolmistress, a Poem in imitation of Spenser. . . .* The original was Sarah Lloyd, teacher of the village school where Shenstone received his first education. He inherited the Leasowes estate, and retired there in 1745 to undertake what proved the chief work of his life, the beautifying of his property. He embarked on elaborate schemes of landscape gardening which gave the Leasowes a wide celebrity, but sadly impoverished the owner. He corresponded with many of the literary people of the day, especially with Jago, Dodsley, Lady Luxborough and Bishop Percy. The correspondence with Percy shows that Shenstone first suggested the collection of the *Reliques*. Shenstone died on Feb. 11, 1763.

His works were first published by his friend Robert Dodsley (3 vols., 1764–1769). The second volume contains Dodsley's description of the Leasowes. The last, consisting of correspondence with Graves, Jago and others, appeared after Dodsley's death. Other letters of Shenstone's are included in *Select Letters* (ed. Thomas Hill 1778). Samuel Johnson wrote the *Life* prefixed to his works in Chalmers's *British Poets*. *See* also Richard Graves, *Recollections of some particulars in the Life of the Late William Shenstone* (1788); H. Sydney Grazebrook, *The Family of Shenstone the Poet* (1890).

SHEPPARD, JOHN [JACK] (1702–1724), English criminal, was born at Stepney, near London, in December 1702, and was brought up in the Bishopsgate workhouse. He was apprenticed to a carpenter, and at the end of 1723 he was arrested as a runaway apprentice, and thenceforward, he says, "I fell to robbing almost every one that stood in my way," Joseph Blake, known as "Blueskin," being a frequent confederate. In the first six months of 1724 he twice escaped from gaol, and towards the end of that period he was responsible for an almost daily robbery in or near London. Eventually, however, his independent attitude provoked the bitter enmity of Jonathan Wild, who procured his capture at the end of July. Sheppard was tried at the Old Bailey and condemned to death, but, largely thanks to his accomplice, "Edgeworth Bess," he escaped from the condemned cell, and was soon back in his old haunts. In September he was rearrested and imprisoned in the strongest part of Newgate, being actually chained to the floor of his cell, but he escaped through the chimney to the roof of the prison, whence he lowered himself into the adjoining house. After a few days, concealment he was rash enough to reappear in the Drury Lane quarter. He was captured, hopelessly drunk, in a Clare Market tavern and reimprisoned, his cell being now watched night and day. On Nov. 16, 1724 he was hanged at Tyburn. He was then not quite twenty-two.

Sheppard has been a hero of romance, notably in Harrison Ainsworth's novel, *Jack Sheppard* (1839).

See *A Narrative of all the Robberies, Escapes, &c., of John Sheppard*, attributed to Daniel Defoe (London, 1724); *Newgate Calendar*, ed. Knapp and Baldwin; Griffiths, *Chronicles of Newgate*; *British Journal* (August, October 1724); *Weekly Journal* (August, September, November 1724); R. W. Postgate, *Murder, Piracy and Treason* (1926).

SHEPPEY, an island off the Kentish coast of England, included in the north-eastern parliamentary division of Kent. Pop. (1921) 26,344. It is the largest of the several low islands which are separated from the mainland by the ramifying creeks about the mouth of the river Medway. The strait isolating Sheppey is called the Swale. Sheppey is low-lying, with one small elevation slightly exceeding 200 ft. near the north coast, which presents slight cliffs towards the shallow sea. These are frequently encroached upon by the sea, while the flat shore on the south is protected by embankments. Sheppey is 10½ m. in extreme length from east to west, while the greatest breadth is about 5 miles. Sheppey is mostly treeless but very fertile, bearing much grain and vegetables; its name, meaning the "island of sheep," is still appropriate, as great flocks are bred of sheep noted for their mutton. On the west are the port of Queenborough and the naval station of Sheerness. From here the Sheppey light railway runs east through the island, serving Minster and Leysdown, which are in some favour as seaside resorts.

SHEPSTONE, SIR THEOPHILUS (1817–1893), British South African statesman, was born at Westbury near Bristol, England, on Jan. 8, 1817. When he was three years old his father, the Rev. William Shepstone, emigrated to Cape Colony. In the Kaffir War of 1835 Shepstone served as headquarters interpreter on the staff of the governor, Sir Benjamin D'Urban, and at the end of the campaign remained on the frontier as clerk to the agent for the native tribes. In 1838 he was one of the party sent from Cape Colony to occupy Port Natal on behalf of Great Britain. This force was recalled in 1839, when Shepstone was appointed British resident among the Fingo and other tribes in Kaffraria. Here he remained until the definite establishment of British rule in Natal and its organization as an administrative entity, when he was made (1845) agent for the native tribes. In 1848 he became captain-general of the native levies; in 1855 judicial assessor in native causes; and, in 1856, on the remodelling of the Natal government, secretary for native affairs and a member of the executive and legislative councils. This position he held until 1877. The main line of his policy was to maintain tribal customs as far as consistent with principles of humanity, and not to attempt to force civilization.

Shepstone's influence with the Zulus was made use of by the Natal government; in 1861 he visited Zululand and obtained from Panda a public recognition of Cetywayo as his successor. Twelve years later Shepstone attended the proclamation of Cetywayo as king, the Zulu chief promising Shepstone to live at peace with his neighbours. In 1874 and again in 1876 Shepstone was in London on South African affairs, and to his absence from Natal Cetywayo's failure to keep his promises is, in part, attributed. When in London in 1876 Shepstone received discretionary powers from the 4th earl of Carnarvon, then secretary of state for the colonies under which he went to Pretoria in Jan. 1877, and on April 12, issued a proclamation announcing the establishment of British authority over the Transvaal. Shepstone remained as administrator of the Transvaal until Jan. 1879; his rule was marked, according to Sir Bartle Frere, who described him as "a singular type of an Africander Talleyrand," by an "apparent absence of all effort to devise or substitute a better system" than that which had characterized the previous régime. Shepstone had been summoned home to advise the Colonial Office on South African affairs and he reached England in May 1879; on his return to Natal he retired (1880) from the public service. In 1883, however, he was commissioned to replace Cetywayo as king in Zululand. He was active in church matters in Natal, and a friend of Bishop Colenso. He opposed the grant of self-government to Natal. He died at Pietermaritzburg on June 23, 1893.

SHEPTON MALLET, a market town in the Wells parliamentary division of Somersetshire, England, 22 m. S.W. of Bath. Pop. of urban district (1931) 4,108. The old town extends in a narrow line along the river Sheppey, while the newer town has for its main street a viaduct across the river valley. The church of St. Peter and St. Paul is especially noteworthy. Consisting of a chancel, clerestoried nave, and aisles, it is Early English and Perpendicular in style, and contains a beautiful 13th-century oak roof of 350 panels, each with a different design; and a 15th-century pulpit of carved stone. The market cross, over 50 ft. high, and one of the finest in Somerset, was erected in 1500. Shepton possesses a grammar school of the 17th century, and a science and art school. There are large breweries, roperies, potteries, and, in the neighbourhood, marble, granite and lime works.

Shepton, before the conquest called Sepeton, was in the possession of the abbots of Glastonbury for four hundred years. The town received the grant of a market from Edward II.

SHERANI or SHIRANI, a Pathan tribe on the Dera Ismail Khan border of the North West Frontier Province of India who occupy the country and the Takht-i-Suliman, thence eastward down to the border of Dera Ismail Khan district. Sheranis are generally of middling stature, thin, but hardy and active. They have bold features, high cheek-bones, and are wild and manly. Their chief occupation is agriculture, but they carry on an extensive trade in Dera Ismail Khan district. There are two well-defined branches called Bargha and Largha, or the Highlands and the Lowlands. Marriage is adult. Dowry is paid and divorce is usually a repurchase of the woman for half the sum (less the dowry) received for her.

See Tribes and Castes of the Punjab and North West Frontier Province vol. iii. 1914.

SHERATON, THOMAS (*c.* 1751–1806), next to Chippendale the most famous English furniture-designer and cabinet-maker, was born in humble circumstances at Stockton-on-Tees and died at 8, Broad Street, Golden Square, on Oct. 22, 1806. He picked up drawing and geometry and appears to have been apprenticed to a cabinet-maker. Of his career as a maker and designer of furniture nothing is known until he is first heard of in London in 1790, to which he came probably while still a young man. It is not known to what extent, if at all, he worked with his own hands, or whether he confined himself to designing furniture. Such evidence as there is points to artistic, rather than mechanical work, after he began to write, and it is certain that he gave drawing lessons. The remarkable series of volumes of designs for furniture which he published during the last sixteen years of his life, and upon which his fame depends, were not a commercial success. He was a great artistic genius who lived in chronic poverty.

His first book on furniture was published in 1791 with the title of *The Cabinet-Maker and Upholsterer's Drawing Book.* It was issued in parts by T. Bensley, of Bolt Court, Fleet Street; there was a second edition in 1793 and a third in 1802. The designs in the book are exceedingly varied and unequal, ranging from pieces of perfect proportion and the most pleasing simplicity to efforts ruined by too abundant ornament. Some of the chair-backs, delightful in their grace and delicacy, show the influence of Hepplewhite and Adam—it has been suggested that he collaborated with the Adams. Sheraton, like his predecessors, made extensive use not so much perhaps of the works of other men as of the artistic ideas underlying them which were more or less common to the taste of the time. His slender forms and sweeping curves were, however, his own inspiration, and his extensive use of satin-wood differentiated his furniture from most of that which had preceded it.

Sheraton's books, like those of the other great cabinet-makers of the second half of the 18th century, were intended for the practical use of the trade, although it is reasonable to suppose that he obtained orders by the publication of his books and employed other cabinet-makers to manufacture the work. Of his own actual manufacture only one piece is known with certainty—a glass-fronted book-case, of somewhat frigid charm, stamped "T.S." on the inside of one of the drawers. It lacks the swan-necked pediment so closely associated with his style. *The Drawing Book* was followed in 1802 by *The Cabinet Dictionary, containing an Explanation of all the Terms used in the Cabinet, Chair and Upholstery branches, containing a display of useful articles of furniture,* illustrated with eighty-eight copperplate engravings. The text in alphabetical form, has a supplement with articles on drawing and painting, and a list of "most of the master-cabinet-makers, upholsterers, and chair makers," 252 in number, then living in and around London. Some of the designs show the tendency to the tortured and the bizarre which disfigured so much of Sheraton's later work. This debased taste reached its culmination in *The Cabinet Maker, Upholsterer and General Artists' Encyclopedia,* the publication of which began in 1804. It was to consist of 125 numbers, but when the author died only a few had been issued.

Many charming little work-tables bear Sheraton's attribution, and he designed many beautiful sideboards and bookcases. Sheraton's ingenuity had led him to devise many of the ingenious pieces of combination or "harlequin" furniture which the later 18th century loved. Thus a library table would conceal a step-ladder, a dressing table would be also a washstand and an escritoire—looking-glasses would enclose dressing-cases, writing-tables or work-tables. But his most astonishing fancy was an ottoman with "heating urns" beneath, "that the seat may be kept in a proper temperature in cold weather."

Sheraton's genius was less sane and less balanced than that of Chippendale, for despite his excursions into the Chinese and Louis Quinze manners, Chippendale always produced an impression of English work. Sheraton's adaptability, his readiness to receive foreign impressions, the lightness of his forms and the grace of his conceptions had about them a touch of the exotic which was heightened by his lavish employment of satin-wood and other beautifully grained woods susceptible of a high polish. The severe and balanced forms, the delicate inlay, the occasional slight carving in low relief, the painted enrichments, the variety of the backs and legs of his chairs produce an impression of lightness and grace that has never been surpassed; whether he designed a little knife-case or the body of a long clock, harmony, proportion and a delicate fancy were ever present. "Sheraton," like "Chippendale," has come to indicate a style rather than a personal attribution. Unfortunately his later extravagant creations in the Empire style had much to do with the development of a fashion of English Empire which finally ruined British furniture design.

See *Gentleman's Magazine* (1806), II., 1082; also "Memoir of Adam Black," in *Magazine of Art* (1883), p. 190.

SHERBORNE, a market town of Dorsetshire, England, 118 m. W.S.W. from London by the S.R. Pop. of urban district (1931), 6,542. It lies near the border of Somersetshire, on the southern slope of a hill overlooking the river Yeo, in a fertile, well-wooded district.

There is no evidence of Roman or British settlement, and it is probable that Sherborne (Scireburn, Shireburne) grew up after the Saxon conquest of the region in the middle of the 7th century. It is first mentioned in 705 as the place where St. Aldhelm fixed his bishop-stool for the new diocese of Western Wessex. Freedom from Danish attacks at the end of the 9th century was a factor in making Sherborne the capital of Wessex. In 978 Bishop Wulfsey introduced the stricter form of Benedictine rule into his cathedral of Sherborne, and became the first abbot. The see, which was united with that of Ramsbury in 1058, was removed to Old Sarum in 1075. On the separation of the offices of bishop and abbot in 1122, the abbot's fee was carved out of the bishop's manor, but did not include the town. Bishop Roger of Caen (1107–1139) built the castle. Its strength made Stephen force Bishop Roger to surrender it in 1139; it fell afterwards into the hands of Maud. It was later granted to the earls of Salisbury, who seem to have allowed it to fall into disrepair, for in 1315 and in 1319 the abbot of Sherborne was appointed to inquire into its condition. It was recovered by the bishop in 1355, and retained by the see until granted in 1599 to Elizabeth, who gave it to Sir Walter Raleigh. The town suffered very severely during the civil wars, the castle being besieged by the parliamentary forces in 1642 and 1645. Fairs held on the 8th of May, the 26th of July and the first

Monday after the 10th of October were granted to the bishop in 1227, 1240 and 1300. The abbey church of St. Mary the Virgin is a cruciform building with central tower, the nave and choir having aisles and clerestory. Some pre-Norman work appears in the western wall, the tower arches and south porch are Norman, and there are an Early English chapel and some Decorated windows. The church, however, was almost wholly reconstructed in the Perpendicular period, and is a fine example of that style. The colour-decoration in the choir; and the stone-vaulted roof with fan tracery are very fine. The almshouse known as the hospital of St. John the Baptist and St. John the Evangelist was founded in 1437 on the site of an earlier establishment, and retains a Perpendicular chapel, hall and other portions. Of the old castle, the gatehouse and other parts are of Norman construction, but the mansion near it was built by Sir Walter Raleigh.

After the decline of the mediaeval trade in cloth, lace and buttons were the only articles manufactured here until the introduction of silk-weaving in 1740. The town is now the centre of an agricultural region.

SHERBROOKE, ROBERT LOWE, Viscount (1811–1892), British statesman, was born on Dec. 4, 1811 at Bingham, Notts, where his father was the rector. He was educated at Winchester and at University College, Oxford. In 1835 he won a fellowship at Magdalen, but vacated it on his marriage in 1836, with Miss Georgina Orred (d. 1884). In 1841 Lowe moved to London, to read for the Bar ("called" 1842); but his eyesight began to fail, and, acting on medical advice, he went to Sydney, where he set to work in the law courts. In 1843 he was nominated to a seat in the New South Wales Legislative Council; owing to a difference with Gipps he resigned his seat, but was elected shortly afterwards for Sydney. In 1850 he went back to England, and began to write leaders for *The Times*. In 1852 he was returned to Parliament for Kidderminster in the Liberal interest. Between 1853 and 1858 he was secretary of the Board of Control and vice-president of the Board of Trade. In 1859 he went to the Education Office as vice-president of the Council in Lord Palmerston's ministry. In 1864 he resigned; in 1868 he became chancellor of the exchequer. In 1873 he was transferred to the Home Office, but in 1874 the government resigned. When the Liberals returned to power in 1880 he was raised to the peerage as Viscount Sherbrooke, but from 1875 till his death at Warlingham, Surrey, on July 27, 1892, his health was constantly failing, and by degrees he figured less and less in public life.

Bobby Lowe, as he was popularly known, was one of the most remarkable personalities of his day, with his tall, striking figure, albino complexion and hair, and faculty for epigram and irony. During the 'seventies the following epitaph was suggested for him by one of the wits of his day:—

Here lies poor old Robert Lowe;
Where he's gone to I don't know;
If to the realms of peace and love,
Farewell to happiness above;
If, haply, to some lower level,
We can't congratulate the devil.

His literary talent, though mainly employed in journalism, was also shown in a little volume of verses, *Poems of a Life* (1884). He married a second time, in 1885, but left no children.

See *Life and Letters* by A. Patchett Martin (London, 1893).

(H. C.)

SHERBROOKE, a city and port of entry of Quebec, Canada, and capital of Sherbrooke county, 101 m. E. of Montreal, at the confluence of the rivers Magog and St. Francis, and on the Canadian National, Canadian Pacific and Quebec Central railways. Pop. (1931) 28,933. It is the seat of a Roman Catholic bishopric and of the district courts, and contains manufactories of woollen and cotton goods and machinery, also saw and grist mills. It derives its name from Sir John Coape Sherbrooke (1764–1830), who from 1816 to 1818 was governor-general of Canada.

SHERE ALI KHAN (1825–1879), Amir of Afghanistan, was born in 1825, one of the sons of the amir Dost Mahommed, whom he succeeded in 1863. Supported by the viceroys of India, Lord Lawrence and Lord Mayo, Shere Ali remained on good terms with the British government for some years; but after the rebellion of his son Yakub Khan, 1870–74, he leaned towards Russia, and welcomed a Russian agent at Kabul in 1878, and at the same time refused to receive a British mission. This led to long negotiations, and ultimately to war, when the British forced the Khyber Pass in November 1878, and defeated the amir's forces on every occasion. Shere Ali fled from his capital and, taking refuge in Turkistan, died at Mazar-i-Sharif on Feb. 21, 1879.

SHERIDAN, FRANCES (1724–1766), wife of Thomas Sheridan (1719–1788) (*see* below) and mother of the dramatist Richard Brinsley Sheridan (*q.v.*) was the daughter of Dr. Philip Chamberlaine of Dublin. When only 15 years of age she wrote a story, *Eugenia and Adelaide,* published after her death in two volumes. She took Sheridan's part in the Kelly riots, writing some verses and a pamphlet in his defence. This led to her marriage in 1747 with the unpopular manager. It was by Richardson's advice that she wrote the *Memoirs of Miss Sidney Bidulph.* It was issued anonymously in 1761 with a dedication to Richardson, and had great success, both in England and France. A second part (2 vols.) was published in 1767. Two of her plays were produced in 1763 at Drury Lane, *The Discovery* and *The Dupe.* The former was one of Garrick's stock pieces, and Sir Anthony Branville one of his favourite characters. *The Dupe* was a failure and was only played once. Her last work was an Oriental tale, *Nourjahad,* written at Blois, where she died on Sept. 26, 1766.

See Alicia Lefanu, *Memoirs of the Life and Writings of Mrs. Frances Sheridan* (1824).

SHERIDAN, PHILIP HENRY (1831–1888), American soldier, was born at Albany, N.Y., on March 6, 1831. His parents, who had recently migrated from Ireland, moved to Perry county, O., a year after Philip's birth. Obtaining through his own endeavours an appointment to West Point, he graduated in 1853. He had gained some experience in fighting Indians on the frontier when the Civil War began in 1861. A first lieutenant at the time, he was soon promoted to captain, and in the spring of 1862 became colonel of the 2nd Michigan cavalry under Halleck in Tennessee. In July he was raised to the rank of brigadier general of volunteers as a result of his skilful conduct in the battle of Booneville (July 1). He was in charge of the 11th division of the Army of the Ohio under Buell in the battle of Perryville (Oct. 8); and under Rosecrans at Stone's river (Dec. 26) he won promotion to the rank of major general of volunteers. In the summer of 1863 he effectively supported Rosecrans in manoeuvring the Confederates under Bragg out of middle Tennessee. Following the latter into northern Georgia in September, Rosecrans met with a signal defeat at Chickamauga (*q.v.*) on the 20th, his army being driven in confusion back to Chattanooga, Tenn. Sheridan's cavalry division, though driven back in the course of the battle, helped to cover the retreat. In the subsequent fighting around Chattanooga (*q.v.*) Sheridan won considerable distinction, especially in his daring and brilliant charge up Missionary ridge (Nov. 25). This attracted the notice of Gen. Grant, who, when he became lieutenant general (March 1864) and assumed command of the Army of the Potomac in Virginia, placed Sheridan in charge of his cavalry. In this capacity he proved himself the most able cavalry leader on the Union side. His corps were active in the battles of the Wilderness (*q.v.*) and Spottsylvania Court House (May 5–21). While the latter was still in progress he was sent on a raid toward Richmond, in the course of which he cut the Confederate communications by destroying railroads and cutting telegraph wires. He returned to the main army in time to participate in the battle of Cold Harbor (*q.v.*). Soon afterward he set out upon a raid toward Charlottesville (June 7–26) for the purpose of co-operating with Gen. David Hunter in the Valley.

The success of these expeditions led to his appointment (Aug. 7) to the command of a newly formed Army of the Shenandoah with instructions to clear the Valley of the Confederates. This was the greatest opportunity of his military career, and he proved himself fully equal to it. His campaign was brilliant and decisive. He defeated Gen. Early at Winchester (Sept. 19) and again at Fisher's Mill (Sept. 22). Then followed an act concerning which he has often been severely censured. In order to make the region

useless to the Confederates, he destroyed all means of subsistence; so that one of the most fruitful regions in the South was left in utter desolation with non-combatants on the verge of starvation. At this time Sheridan was given the rank of brigadier general in the regular army. When a few weeks later (Oct. 19) the main body of his army was thrown into confusion by a surprise attack from Gen. Early at Cedar Creek, Sheridan, some 20 m. away, made his famous ride, rallied his troops, and turned defeat into victory. He was then commissioned (Nov. 8) major general in the regular army. He made another raid (Feb. 27–March 24) from Winchester to Petersburg, again destroying supplies and means of communication and defeating Early at Waynesboro. In April he turned Lee's flank at Five Forks and forced him to retreat toward Appomattox where he surrendered to Grant on April 9, 1865.

A month later Sheridan was placed in command of an American force on the Mexican border to watch the struggle between Maximilian, who had been set up as emperor of Mexico by Napoleon III. in 1864, and the Liberals seeking his overthrow. His presence greatly added to the effectiveness of American diplomatic protests to the French Government, thus hastening the collapse of that ill-starred venture. In the spring of 1867 Sheridan was placed in command of the Fifth Military district embracing Louisiana and Texas and stationed at New Orleans. Himself an advocate of extreme measures in dealing with the conquered South he soon came into conflict with President Johnson who opposed such policies. His unconciliatory measures led to his removal in Sept. 1867. He was then placed in charge of the Department of the Missouri. In the winter of 1868–69 he conducted a successful campaign against the Indians. In the latter year he was made lieutenant general by President Grant. During the Franco-German war of 1870 he accompanied the headquarters of the German army as the guest of the king of Prussia. In 1883 he was given chief command of the U.S. army, and five years later, shortly before his death, was raised to the rank of general. He died at Nonquitt, Mass., on Aug. 5, 1888.

In physical appearance Gen. Sheridan was short and stout, and rather harsh-featured. To those opposed to his policies, in peace as in war, he seemed gruff and needlessly severe, but to his friends he was kindly. Exceptionally gifted with personal magnetism, he was very popular with his troops. As a military leader he combined brilliant courage with careful, vigilant tactics. He was a devout Roman Catholic. In 1875 he married Irene, daughter of Gen. D. H. Rucker, U.S.A.

Sheridan's *Personal Memoirs* (2 vols.) were published in 1888. *See* also Davies, *General Sheridan* (1895); Newhall, *With General Sheridan in Lee's Last Campaign* (1866), Channing, *History of the United States*, vol. vi. (1925); W. G. Shotwell, *The Civil War in America* (1925). (A. M. A.)

SHERIDAN, RICHARD BRINSLEY BUTLER (1751–1816), third son of Thomas and Frances Sheridan, was born in Dublin on Oct. 30, 1751. At the age of 11 he was sent to Harrow school, where he spent six years.

After leaving Harrow he kept up a correspondence with a school friend N. B. Halhed who had gone to Oxford, and between them they published (1771) a metrical translation of Aristaenetus. They also wrote a farce entitled *Jupiter*, which was refused by Garrick and Foote and remained in MS. It contains the same device of a rehearsal which was afterwards worked out in *The Critic*. Some of the dialogue is very much in Sheridan's mature manner. The removal of the family to Bath in 1770–1771 led to an acquaintance with the daughters of the composer Thomas Linley. The eldest daughter, Elizabeth Ann (b. 1754), a girl of sixteen, the *prima donna* of her father's concerts, was exceedingly beautiful. Her portrait, by Gainsborough, hangs at Knole, Kent. She had many suitors, among them Sheridan, N. B. Halhed and a certain Major Mathews. To protect her from this man's persecutions, Sheridan escorted Miss Linley, in March 1772, to a nunnery in France, having secretly gone through the ceremony of marriage with her near Calais. He returned and fought two duels with Mathews, while Mr. Linley brought his daughter back to Bath. Sheridan was sent to Waltham Abbey to continue his studies. He was entered at the Middle Temple on April 6, 1773, and a week later he was openly married to Miss Linley.

Although he had no income, and no capital beyond a few thousand pounds brought by his wife, he took a house in Orchard Street, Portman Square, furnished it "in the most costly style," and proceeded to return on something like an equal footing the hospitalities of the fashionable world. His first comedy, *The Rivals*, was produced at Covent Garden on Jan. 17, 1775. It is said to have been not so favourably received on its first night, owing to its length and to the bad playing of the part of Sir Lucius O'Trigger. But at the second performance (Jan. 28) it at once took that place on the stage which it has never lost. His second piece, *St. Patrick's Day, or the Scheming Lieutenant*, a lively farce, was written for the benefit performance (2nd of May 1775) of Lawrence Clinch, who had succeeded as Sir Lucius. In November 1775, with the assistance of his father-in-law, he produced the comic opera of *The Duenna*, which was played 75 times at Covent Garden during that season. Sheridan now began to negotiate with Garrick for the purchase of his share of Drury Lane, and the bargain was completed in June 1776. The sum paid by Sheridan and his partners, Thomas Linley and Dr. Ford, for the half-share was £35,000; of this Sheridan contributed £10,000. The money was raised on mortgage, Sheridan contributing only £1,300 in cash. (*See* B. Matthews's 1885 ed. of Sheridan's Comedies pp. 29–31.) Two years afterwards Sheridan and his friends bought the other half of the property for £35,000.

The direction of the theatre seems to have been mainly in the hands of Sheridan. In February 1777 he produced his version of Vanbrugh's *Relapse*, under the title of *A Trip to Scarborough*. This is printed among Sheridan's works, but he has no title to the authorship. His task was to remove indecencies; he added very little to the dialogue. *The School for Scandal* was produced on May 8, 1777. Mrs. Abington, who had played Miss Hoyden in the *Trip*, played Lady Teazle, who may be regarded as a Miss Hoyden developed by six months' experience of marriage and town life. The lord chamberlain was only persuaded on grounds of personal friendship with Sheridan to license the play. There are tales of the haste with which the conclusion of *The School for Scandal* was written and of a stratagem by which the last act was got out of him by the anxious company, but we know from Sheridan's sister that the idea of a "scandalous college" had occurred to him five years before in connection with his own experiences at Bath. His difficulty was to find a story sufficiently dramatic in its incidents. The dialogue is so brilliant throughout, and the auction scene and the screen scene so effective, that the construction of the comedy meets with little criticism. *The School for Scandal*, though it has not the unity of *The Rivals*, nor the same wealth of broadly humorous incident, is universally regarded as Sheridan's masterpiece.

The Critic was produced on Oct. 29, 1779, *The School for Scandal* meantime continuing to draw larger houses than any other play every time it was put on the stage. In *The Critic* the laughable infirmities of authors, actors, patrons and audience are touched off with the lightest of hands; the fun is directed, not at individuals, but at absurdities that grow naturally out of the circumstances of the stage. It seems that he had accumulated notes for another comedy to be called *Affectation*, but his only other play was *Pizarro*, produced in 1799—a tragedy in which he made liberal use of the arts ridiculed in the person of Mr. Puff. He also revised for the stage Benjamin Thompson's translation, *The Stranger*, of Kotzebue's *Menschenhass und Reue*.

He entered parliament for Stafford in 1780, as the ally of Charles James Fox. He is said to have paid the burgesses five guineas each for the honour of representing them. His first speech in parliament was to defend himself against the charge of bribery, and was well received. Congress recognized his services in opposing the war in America by offering him a gift of £20,000 which, however, he refused. Under the wing of Fox he filled subordinate offices in the short-lived ministries of 1782 and 1783. He was under-secretary for foreign affairs in the Rockingham ministry, and a secretary of the treasury in the Coalition ministry. In those heated days of parliamentary strife he was almost the only man of mark that was never called out, and yet he had no

match in the weapon of ridicule.

Sheridan found his great opportunity in the impeachment of Warren Hastings. His speeches were by the unanimous acknowledgment of his contemporaries among the greatest delivered in that generation of great orators. The first was on Feb. 7, 1787, on the charges brought against Hastings with regard to the begums or princesses of Oude. Sheridan spoke for more than five hours, and the effect was such that it was unanimously agreed to postpone the final decision till the House should be in a calmer mood. Of this, and of his last great speech on the subject in 1794, only brief abstracts have been preserved; but the second, the four days' speech delivered in his capacity of manager of the trial, in Westminster Hall, on the occasion so brilliantly described by Macaulay, is given in Gurney's verbatim reports of the speeches on both sides at the trial, published at Sir G. Cornewall Lewis's instigation in 1859. There are passages of gaudy rhetoric, loose ornament and declamatory hyperbole; but the strong common sense, close argumentative force and masterly presentation of telling facts enable us to understand the impression produced by the speech at the time.

From the time of the break-up of the Whig party on the secession of Burke he was more or less an "independent member," and his isolation was complete after the death of Fox. When Burke denounced the French Revolution, Sheridan joined with Fox in vindicating the principle of non-intervention. But when it became apparent that France under Napoleon would interfere with the affairs of its neighbours, he employed his eloquence in denouncing Napoleon and urging the prosecution of the war. One of his most celebrated speeches was delivered in support of strong measures against the mutineers at the Nore. He was one of the few members who actively opposed the union of the English and Irish parliaments. When the Whigs came into power in 1806 Sheridan was appointed treasurer of the navy, and became a member of the Privy Council. After Fox's death he succeeded his chief in the representation of Westminster, and aspired to succeed him as leader of the party, but this claim was not allowed, and thenceforward Sheridan fought for his own hand. When the prince became regent in 1811 Sheridan's private influence with him helped to exclude the Whigs from power. Throughout his parliamentary career Sheridan was one of the boon companions of the prince, and his champion in parliament in some dubious matters of payment of debts. But he always resented any imputation that he was the prince's confidential adviser or mouthpiece. A certain proud and sensitive independence was one of the most marked features in his parliamentary career.

His last years were harassed by debt and disappointment. At the general election of 1807 he stood again for Westminster and was defeated, but was returned as member for Ilchester, at the expense apparently of the prince of Wales. In 1812 he failed to secure a seat at Stafford. As a member of parliament he had been safe against arrest for debt, but now his creditors closed in upon him. It may be regarded as certain, however, that the description of the utter destitution of the last weeks of his life given in the *Croker Papers* (i. pp. 288–312, ed. L. J. Jennings) is untrue. It was not without reason that his grand-daughter Mrs. Norton denounced the unfairness of judging the real man from unauthenticated stories; and against reports of his reckless management of his affairs we must set the facts that he had no source of income but Drury Lane theatre, that he bore from it for thirty years all the expenses of a fashionable life, and that the theatre was twice rebuilt during his proprietorship. Enough was lost in this way to account ten times over for all his debts. The records of his wild bets in the betting book of Brooks's Club date from the years after the loss, in 1792, of his first wife, to whom he was devotedly attached. He married again in 1795, his second wife being Esther Jane, daughter of Newton Ogle, dean of Winchester. He died on July 7, 1816, and was buried with great pomp in Westminster Abbey.

Sheridan's only son by his first marriage, THOMAS SHERIDAN (1775–1817), was a poet of some merit. He became colonial treasurer at the Cape of Good Hope.

BIBLIOGRAPHY.—*Memoirs of the . . . Life of . . . R. B. Sheridan, with a Particular Account of his Family and Connexions* (1817), by John Watkins made many false statements. The *Memoirs, etc.* (1825), compiled by Thomas Moore did not make full use of the papers submitted by the family. William Smyth (*Memoir of Mr. Sheridan,* 1840), who had been a tutor in Sheridan's house, was responsible for many of the scandalous stories connected with Sheridan's name. Of modern works and critical stories *see* W. Fraser Rae, *Wilkes, Sheridan, Fox* (1874), the *Letters and Journals* of Byron (especially vol. v. p. 411 *seq.,* ed. Prothero, 1901); Mrs. Oliphant, *Sheridan* (1883) in the "English Men of Letters" series; Percy Fitzgerald, *Lifes of the Sheridans* (2 vols., 1886); and the *Life of R. B. Sheridan* (1890) by Lloyd C. Sanders in the "Great Writers" series and W. Fraser Rae, *Sheridan: a Biography* (2 vols., 1896). The *Life of R. B. Sheridan* by Walter Sichel (1909) is the best account now available.

Among the numerous modern editions of Sheridan's plays, of which only *The Rivals* was published by the dramatist himself, may be mentioned: *Sheridan's Plays now printed as he wrote them* (1902), edited by W. Fraser Rae; *The Plays of R. B. Sheridan* (1900), edited by A. W. Pollard; and *Sheridan's Comedies* (Boston, U.S.A., 1885), with a valuable introduction by Brander Matthews. For further details consult the bibliography by J. P. Anderson in the *Life* by Lloyd C. Sanders.

SHERIDAN, THOMAS (1687–1738), grandfather of the dramatist, Richard Brinsley Sheridan (*see* above), was born at Cavan and educated at Trinity College, Dublin. He married Elizabeth, heiress of Charles MacFadden, and thereby restored to the Sheridan family Quilcagh House, which they had forfeited by their Jacobite sympathies. When Swift came to Dublin as dean of St. Patrick's, Sheridan was a schoolmaster of high repute, and the two men were soon close friends. Sheridan was his confidant in the affair of *Drapier's Letters;* and it was at Quilcagh House that *Gulliver's Travels* was prepared for the press. Through Swift's influence he obtained a living near Cork. His correspondence with Swift and his whimsical "Art of Punning" make clear from whom his grandson derived his high spirits. He was no mean scholar, and translated the *Philoctetes* of Sophocles (1725), the *Satires* of Perseus (1728), and the *Satires* of Juvenal (1739). His latter days were not prosperous. He offended Swift by fulfilling an old promise to tell the dean if he ever saw signs of avarice in him, and the friends parted in anger. He died in poverty on Oct. 10, 1738.

SHERIDAN, THOMAS (1719–1788), son of Thomas Sheridan (1687–1738; *see* above), was born in Dublin in 1719. His father sent him to Westminster; but he completed his education at Trinity college, Dublin, where he took his B.A. in 1739. Then he went on the stage, and wrote a play, *Captain O'Blunder, or the Brave Irishman,* which became a stock piece, though it was never printed. His first appearance in London was at Covent Garden in March 1744, when he acted for three weeks in a succession of leading parts, Hamlet being the first. In October he appeared at Drury Lane, playing Horatio in Rowe's *Fair Penitent,* and subsequently as Pierre in Otway's *Venice Preserved,* and in Hamlet and other parts. In 1747 he became manager of the Theatre Royal, Dublin, and married Frances Chamberlaine, the novelist. He conceived a scheme of British education, and to push this he lectured at Oxford and Cambridge, being incorporated M.A. in both universities. But the scheme did not make way, and in 1760 he was acting under Garrick at Drury Lane. As an actor, he is placed by Churchill (*Rosciad* l. 987) in the second rank, next to Garrick, but there is no hint of possible rivalry, and he is described as one whose conceptions were superior to his powers of execution, whose action was always forcible but too mechanically calculated, and who in spite of all his defects rose to greatness in occasional scenes. Through Sheridan's efforts Samuel Johnson had been given a pension, and so impressed was Lord Bute with Sheridan's own scheme for a *Pronouncing Dictionary* that he granted him a pension of £200 a year.

In 1764 he went to live in France, partly for Mrs. Sheridan's health, partly to study the system of education. His wife died in 1766 and soon afterwards he returned to England. In 1769 he published a matured *Plan of Education for the Young Nobility and Gentry,* and in 1780 his *General Dictionary of the English Language* (2 vols.). After his son's brilliant success he assisted in the management of Drury Lane, and occasionally acted. His *Life of Swift,* a very entertaining work in spite of its incompleteness as a biography, was written for the 1784 edi-

tion of Swift's works. He died at Margate on Aug. 14, 1788.

SHERIDAN, a city of northern Wyoming, U.S.A., at the confluence of Big and Little Goose Creeks, 3,737 ft. above sea-level; the county seat of Sheridan county and the largest city in the northern part of the State. It is on Federal highways 87E and 116, and is served by the Burlington (railway) route. Pop. (1920) was 9,175, 91% native white; in 1930 it was 8,536. The city lies in a broad green valley, surrounded by the snow-capped peaks of the Big Horn mountains. The Big Horn National Forest (1,136,000 ac.) in which are two living glaciers, many peaks 10 to 12,000 ft. high, over 200 lakes, and 1,200 m. of trout streams, is about 15 m. west. Sheridan is a division point on the Burlington, which maintains repair shops and an extensive tie-treating plant here; and is the wholesale and jobbing centre of a wide territory, devoted largely to stock-raising and the production of wool, diversified farming and dairying. Coal (sub-bituminous) is mined near the city, which has a large flour mill, beet-sugar factory, creamery, iron works, brick and tile plant and other manufacturing industries. The assessed valuation of property in 1927 was over $11,000,000, and bank debits totalled $46,881,545. The city was planned in 1882 by J. D. Loucks, who named it in honour of his commander in the Civil War. It was incorporated in 1884.

SHERIFF or **SHIRE-REEVE,** often called "high sheriff," the English and Irish executive authority in a county, or other place, often called his "bailiwick." The office also exists in about 20 ancient cities and boroughs, among which may be named London, Norwich, York, Bristol, Oxford, Lincoln, Chester and Canterbury in England, and Dublin, Cork, Limerick and other places in Ireland. In most of these the office is of an honorary nature. The office is at present an annual one, though this has not been always the case. Three names are put on the list by the chancellor of the exchequer and the judges of king's bench division on the morrow of St. Martin, Nov. 12, and the first name is usually pricked by the king in council in the February or March following. City and borough sheriffs are usually appointed by the corporations on November 9. London and Middlesex are specially provided for by the act of 1887, s. 33, and the sheriffs of the counties of Cornwall and Lancaster are separately appointed, the act not applying to them.

The shrievalty was at one time an important office. The appointment appears to have been originally by popular election, a right confirmed by 28 Edw. I. c. 8, but ultimately vested in the crown except where the office was hereditary. At one time contributions to the expense of the office were made by the magistrates and others of the county. "Sheriff-tooth" was a tenure on condition of supplying entertainment to the sheriff at the county court. Up to the 19th century "riding with the sheriff" was an incident of the assizes, the riders being some of the principal men of the shire who brought with them wine and victuals in order to assist the sheriff in showing hospitality to the judges.

To-day the duties of the sheriff depend on numerous statutes beginning with 2 Edw. III. c. 3 (1328). The most important is the Sheriffs act 1887, mainly a consolidating act applying to England only. The person nominated is usually a magistrate for the county, but anyone is eligible if he has land in the county. Exempt are peers, clergy, officers in active service, practising barristers and solicitors and others. Poverty is also a ground of exemption. The sheriff appoints his undersheriff. The duties of the office are both administrative and judicial. He attends on the judges at assizes and election petitions and is responsible for the execution of writs and of the sentence of death, acts as returning officer at parliamentary elections, prepares the panel of jurors for assizes and is liable for the safe custody of prisoners. He or his deputy sits to assess damages under the Lands Clauses Act 1845, and also in cases sent to the sheriff's court for the assessment of damages. The expenses of the office are partly met by the Treasury. A sheriff cannot during his year of office act as a magistrate for the county of which he is sheriff.

See Sir M. Hale, *A Short Treatise Touching Sheriff's Accompts* (1683); W. Greenwood, *Bouleuterion* (1685); *The Compleat Sheriff* (1696); F. Pollock and F. W. Maitland, *Hist. Eng. Law* (1898); W. S. Holdsworth, *Hist. Eng. Law* (1903); P. E. Mather, *Compendium of Sheriff and Execution Law* (1903); W. S. McKechnie, *Magna Carta* (1905).

Scotland is divided into 15 territorial sheriffdoms in each of which a sheriff exercises administrative and judicial functions; his administrative functions being partly statutory, partly the result of custom. He is Returning Officer in Parliamentary elections for constituencies within his sheriffdom. The appointment, tenure of office and judicial duties of a sheriff are fixed by the Sheriff Court (Scotland) Acts, 1907 and 1913. The sheriff, in his judicial aspect, is one of the judges of the Sheriff court of the sheriffdom. That court, exercising an extensive local jurisdiction, in matters civil and criminal, comprises, on its civil side, a court of first instance and an appellate court, but on its criminal side it has no general appellate jurisdiction. The sheriff sits as the single appellate judge in the Appeal court.

The original jurisdiction of the Sheriff court is, generally speaking, exercised by the salaried sheriff-substitutes attached to the sheriffdom. At the present day the sheriff and salaried sheriff-substitutes are appointed by the Crown on the recommendation of the secretary of State for Scotland. The sheriff, to be appointed, must be an advocate or a salaried sheriff-substitute of five years' standing. He is removable by order of secretary of State for Scotland proceeding upon a report of the Lord President of the Court of Session and the Lord Justice Clerk declaring the sheriff, by reason of inability, neglect of duty or misbehaviour, to be unfit for his office. The order of the secretary of State must lie before both Houses of Parliament for four weeks before it becomes operative. The qualification for appointment as salaried sheriff-substitute is that he shall be an advocate or a law agent in Scotland of five years' standing. The salaried sheriff-substitute is removable from office by the secretary of State for Scotland *de plano* upon a report by the Lord President and the Lord Justice clerk for inability or misbehaviour.

Honorary sheriff-substitutes are appointed by writing under the hand of the sheriff and they hold office during his pleasure.

Besides the sheriffs of counties, there is a sheriff of Chancery appointed by the Crown whose duties are confined to the service of heirs.

See W. J. Lewis, *Sheriff Court Practice* (1923).

Ireland.—The sheriff has much the same duties as in England His position is defined by numerous statutes, beginning with 53 Geo. III. c. 68 (1817).

United States.—The office of sheriff is generally elective. The sheriff has administrative and limited judicial authority. He sometimes serves for combined counties, as in England for Cambridge and Huntingdon. (J. WA.)

SHERIFFMUIR, a battlefield situated on the verge of the extreme north-western flank of the Ochils, Perthshire, Scotland, watered by Wharry Burn, an affluent of the Allan. It lies within the bounds of the parish of Dunblane, 2½m. E. by N. of the town. It was the site of an indecisive battle (Nov. 13, 1715) between the Jacobites, about 12,000 strong, under John Erskine, earl of Mar, and 4,000 Royalists under Archibald Campbell, afterwards duke of Argyll. Both sides, each of which lost 500 men, claimed the victory, although in point of fact Mar deemed it prudent to retreat. The "battle stone" enclosed by a railing marks the scene of the encounter.

SHERMAN, JAMES SCHOOLCRAFT (1855–1912), American politician, was born near Utica, N.Y., on Oct. 24, 1855. He graduated at Hamilton college in 1878 and was admitted to the bar in 1880. He was elected mayor of Utica in 1884. In 1886 he was elected to the U. S. House of Representatives and was returned continuously until 1908, excepting the term 1891–93. He was chairman of the Republican State convention in 1895, 1900 and 1908; and chairman of the Republican national committee in 1906. At the Republican national convention of 1908 he was nominated vice-president and was elected on the ticket with William Howard Taft. Four years later he was renominated, but died at Utica, on Oct. 30, 1912, shortly before the elections.

SHERMAN, JOHN (1823–1900), American financier and statesman, a younger brother of Gen. W. T. Sherman, was born at Lancaster, O., on May 10, 1823. He began the study of law

at Mansfield, O., and was admitted to the bar in 1844. For ten years he practised his profession with success, and with only casual interest in politics, but upon the repeal of the Missouri Compromise by the Kansas-Nebraska bill in 1854, he joined the great popular movement in Ohio against the policy represented by this bill, and was elected to Congress in the autumn of that year as an "Anti-Nebraska" man. In the summer of the next year he took an active part in the formal organization of the Republican Party in the State, and at the opening of Congress in December began a long career of public service. As a member of the House (1855–61) he quickly manifested the qualities which characterized his whole political life. Though a thorough and avowed partisan, he was within the party the counsellor of moderate rather than extreme measures, and thus gained on the whole a position of great influence. He was a member of the committee sent by the House in 1856 to investigate the troubles in Kansas, and drafted the report of the majority. In March of 1861 he took his seat in the Senate in which he sat continuously until he became secretary of the Treasury in 1877. His interest and efficiency in financial legislation in the House led to his appointment on the Senate committee of finance, and after 1867 he was chairman of this influential committee. He thus became associated with the enactment of all the great fiscal laws through which the strain of war and of reconstruction was sustained. He gave earnest support to the Legal Tender Act, and the substitution of the national for the State banking system. The Resumption Act of 1875, which provided for the return of specie payments four years later, was largely his work, and his appointment to the head of the Treasury department by President Hayes in 1877 enabled him to carry the policy embodied in the law to successful execution.

At the end of the Hayes administration he was again elected to the Senate from Ohio and held his seat until 1897. During this period he was largely concerned in the enactment of the Anti-Trust Law of 1890, and of the so-called Sherman Act of the same year, providing for the purchase of silver and the issuing of Treasury notes based upon it. In 1880 and 1888 he aspired actively to the Republican nomination for the Presidency, but failed to obtain the requisite support in the Convention. During the last years of his senatorial career he was chairman of the Senate committee on foreign affairs. Upon the accession of President McKinley in 1897, he became secretary of State; but under the tension of the war with Spain the duties of the office became too exacting for his strength at his age, and in April 1898 he resigned and withdrew into private life. He died at Washington on Oct. 22, 1900.

A selection from the correspondence of John Sherman and his brother Gen. W. T. Sherman was published as *The Sherman Letters* in 1894. Sherman published *Recollections of Forty Years in the House, Senate and Cabinet: an Autobiography* (Chicago, 1895). A volume of *Selected Speeches* was published in 1879. See *Life*, by T. E. Burton (1906).

SHERMAN, ROGER (1721–1793), American political leader, a signer of the Declaration of Independence, was born in Newton (Mass.), on April 19, 1721 (Old Style). He removed with his parents to Stoughton in 1723, attended the country school there, and learned the cobbler's trade in his father's shop. Removing to New Milford (Conn.), in 1743, he worked as county surveyor, studied law, and in 1754 was admitted to the bar. He was treasurer of Yale college in 1765–76, a delegate to the Continental Congress in 1774–81 and again in 1783–84, a member of the Connecticut committee of safety in 1777–79 and in 1782, mayor of New Haven in 1784–93, a delegate to the Federal Constitutional Convention of 1787 and to the Connecticut ratification convention of the same year, and a member of the Federal House of Representatives in 1789–91 and of the U.S. Senate in 1791–93.

He was on the committee which drafted the Declaration of Independence, and also on that which drafted the Articles of Confederation. His greatest public service, however, was performed in the Federal Constitutional Convention. In the conflict between the large State party and the small State party, he and his colleagues played the rôle of peacemakers. In the Federal Congress (1789–93) he favoured the assumption of the State debts, the establishment of a national bank and the adoption of a protective tariff policy. He was strongly opposed to slavery. He died in New Haven on July 23, 1793.

Lewis H. Boutell's *Life of Roger Sherman* (Chicago, 1896), based on material collected by Senator Hoar, is a careful and accurate work.

SHERMAN, WILLIAM TECUMSEH (1820–1891), American general, was born on Feb. 8, 1820, at Lancaster, O. He was descended from Edmond Sherman, who emigrated from England to the Massachusetts bay colony in 1634. His father, Charles R. Sherman, a judge of the supreme court of Ohio, died suddenly in 1829, leaving his widow with a family of young children. William was adopted by Thomas Ewing, a close friend of the father, sometime a senator of the United States and a member of the national cabinet. In 1836 he entered West Point, and on graduating near the head of his class he was appointed second lieutenant. His first field service was in Florida against the Seminole Indians. The usual changes of station and detached duty made him acquainted with the geography of all the Southern states. He also employed much of his time in the study of law. When the war with Mexico began in 1846 he asked for field duty, and was ordered to join an expedition going to California by sea. He was made executive officer in administration of local government till peace came in 1848 and the province was ceded to the United States. In 1850 he married Ellen Boyle, daughter of Thomas Ewing, then secretary of the interior.

In 1853 he resigned from the army and returned to California to conduct at San Francisco a branch of a St. Louis banking-house. He continued successfully in the management of this business until 1857. Afterwards for a short time he was engaged in business at New York and in 1858 practised law at Leavenworth, Kansas. In 1859, the state of Louisiana proposing to establish a military college, Sherman was appointed its superintendent. This institution was opened on Jan. 1, 1860, and here Sherman remained until the spring of 1861, when it was evident that Louisiana would join the states seceding from the Union. He thereupon resigned the superintendency and returned to St. Louis. Though his brother John Sherman was a leader in the party which had elected Lincoln, William Sherman was very conservative on the slavery question, and his distress at what he thought an unnecessary rupture between the states was extreme. Yet his devotion to the national constitution was unbounded, and he offered his services as soon as volunteers for the three years' enlistments were called out.

On May 14, 1861, Sherman was appointed colonel of a new U.S. infantry regiment, and was soon assigned to command a brigade in Gen. McDowell's army in front of Washington, serving with it in the first battle of Bull Run. Promoted brigadier-general of volunteers, Sherman was in August sent to Kentucky to serve under Gen. Robert Anderson. In October he succeeded to the command of the department. Within a month he reported that 200,000 men would be required for the Kentucky campaign. He was relieved of his post soon afterwards in consequence, but the event justified Sherman's view. He was soon re-employed in a minor position, and, at the head of a division of new troops, accompanied Grant's army to Pittsburg Landing. At the battle of Shiloh Sherman's gallant conduct gained him promotion to major-general. He took part in Halleck's advance on Corinth, Miss., and at the close of 1862 led the Mississippi column in the first Vicksburg campaign. He suffered defeat at Chickasaw Bayou, but the capture of Fort Hindman, near Arkansas Post, compensated to some extent for the Vicksburg failure. In Grant's final Vicksburg campaign Sherman commanded the right of the line.

After the surrender (July 4, 1863) Sherman was sent to oppose Gen. Johnston in the country about Jackson, Miss. In July he was made a brigadier-general in the regular army. When, after Rosecrans's defeat at Chickamauga, Grant was placed in supreme command in the west, Sherman succeeded to the command of the Army of the Tennessee, with which he took part in the battle of Chattanooga (*q.v.*). In March, 1864, when Grant became general-in-chief Sherman was made commander of the military division of the Mississippi, including his Army of the Tennessee, now under McPherson, the Army of the Cumberland,

under Thomas, and the Army of the Ohio, under Schofield. Making detachments for garrisons and minor operations in a theatre of war over 500m. wide, he assembled, near Chattanooga, his three armies, aggregating 100,000 men, and began (May 1864) the invasion of Georgia. After a famous campaign of careful manoeuvre and heavy combats (*see* AMERICAN CIVIL WAR), Sherman finally wrested Atlanta (*q.v.*) from the Confederates on Sept. 1.

His able opponent Johnston had been removed from his command, and Hood, Johnston's successor, began early in October a vigorous movement designed to carry the war back into Tennessee. After a devious chase of a month Hood moved across Alabama to northern Mississippi. Sherman thereupon, leaving behind Thomas and Schofield to deal with Hood, made the celebrated "March to the Sea" from Atlanta to Savannah with 60,000 picked men. After a march of 300m. Savannah was reached in December. Railways and material were destroyed, the country cleared of supplies, and the Confederate government severed from its western states. In Jan. 1865 Sherman marched northwards again, once more abandoning his base, towards Petersburg, where Grant and Lee were waging their final campaign. Every mile of his march northwards through the Carolinas diminished the supply region of the enemy, and desperate efforts were made to stop his advance. Gen. Johnston was recalled to active service but his forces were inadequate. Sherman defeated him and reached Raleigh, the capital of North Carolina, on April 13, having marched nearly 500m. from Savannah. Lee's position in Virginia was now desperate. Hood had been utterly defeated by Thomas and Schofield, and Schofield (moved 2,000m. by land and sea) rejoined Sherman in North Carolina. With 90,000 men Sherman drove Johnston before him, and when Lee surrendered to Grant Johnston also gave up the struggle.

Sherman had the good fortune to learn the art of command by degrees. At Bull Run his brigade was wasted in isolated and disconnected regimental attacks, at Shiloh his division was completely surprised owing to want of precaution; but his bravery and energy carried him gradually to the front at the same time as he acquired skill and experience. When therefore he was entrusted with an independent command he was in every way fitted to do himself justice. At the head of 100,000 men he showed, besides the strategy which planned the Carolinas march and the skill in manoeuvre which finally gained Atlanta, the strength of will which sent his men to the hopeless assault of Kenesaw to teach them that he was not afraid to fight, and cleared Atlanta of its civil population in the face of a bitter popular outcry. He is justly regarded as one of the great generals of the Civil War.

When Grant became full general in 1866 Sherman was promoted lieutenant-general, and in 1869, when Grant became president, he succeeded to the full rank. Gen. Sherman retired after being commanding general of the army for 15 years, in 1884. He died at New York on Jan. 14, 1891. An equestrian statue, by Saint Gaudens, was unveiled at New York in 1903, and another at Washington in the same year.

Sherman's *Memoirs* were published in 1875. *See* also Rachel Sherman Thorndike, *The Sherman Letters* (1894); *Home Letters of Gen. Sherman* (1909), edited by M. A. De Wolfe Howe; S. M. Bowman and R. B. Irwin, *Sherman and his Campaigns: a Military Biography* (1865); W. Fletcher Johnson, *Life of William Tecumseh Sherman* (Philadelphia, 1891); Manning F. Force, *General Sherman* (Great Commanders series) (1899); B. H. Liddell Hart, *Sherman* (1929).

SHERMAN, a city of northern Texas, U.S.A., 60 m. N. by E. of Dallas, in the Red River valley; county seat of Grayson county since 1848. It is on Federal highway 75, and is served by the Frisco, the Missouri-Kansas-Texas, the St. Louis Southwestern, the Southern Pacific, and the Texas and Pacific railways. Pop. (1920) 15,031 (84% native white and 14% negroes); 15,713 in 1930 by the Federal census. Cotton, grain and live stock are the principal products. There are large pedigreed seed farms near by, and coal, oil and gas fields within 100 m. The city has 32 wholesale houses and 56 factories. Its mills have a daily capacity of 34 carloads of flour, meal and feeds; its cotton gins and compresses handle 65,000–80,000 bales annually. In 1927 the factory product was valued at $10,978,223. Sherman is the seat of several colleges, including Austin (for men; Presbyterian, 1849) and two junior colleges (Carr-Burdette and Kidd-Key). The city has a commission-manager form of government. Sherman was incorporated as a town in 1858, and chartered as a city in 1895. It was named after General Sidney Sherman, commander of cavalry at the battle of San Jacinto.

SHERRINGTON, SIR CHARLES SCOTT (1861–), British physiologist, was educated at Cambridge, later going as professor to London and Liverpool universities, and finally to Oxford. He has been president of the Royal Society. He is a leading authority on the physiology of the nervous system, and the guiding principles of his work are to be found in his book, *The Integrative Action of the Nervous System.*

SHERRY is the most distinctively Spanish of all wines made in Spain. It is made from grapes grown in a district of which Jerez is the centre, a district which lies, roughly speaking, within an imaginary line drawn from Port St. Mary to Rota, San Lucar, Trebujena, Lebrija, Arcos, and back to Port St. Mary.

The vineyards of the Jerez district are divided into three main classes, according to the nature of the soil. The soil of the best vineyards, those where the finest grapes are cultivated, is calcareous; it is known as *albariza.* The soil of other vineyards is mostly or entirely clay; it is known as *barros.* Lastly, there are vineyards planted in sandy soil, known as *arenas,* from which much wine is made but of a distinctly inferior quality. The drier types of sherry are shipped under the names of *Amontillado* and *Vino de Pasto;* the richer wines under the names of *Oloroso* and *Amoroso.*

Simon, *Wine and Spirits* (1919); *The Blood of the Grape* (1920); *Wine and the Wine Trade* (1921); *The Supply, the Care, and the Sale of Wine* (1923). Don P. Verdad, *From vineyard to decanter* (1876). (A. L. S.)

'S HERTOGENBOSCH, the capital of the province of North Brabant, Holland, at the confluence of the rivers Dommel and Aa, which unite to form the Dieze, and a junction station 29½ m. S.S.E. of Utrecht (also known as 'sBosch, or den Bosch, French *Bois-le-Duc*). Pop. (1927), 41,273. 's Hertogenbosch is a well-built city. The Roman Catholic cathedral of St. John, the Janskerk, with its interior in a state of preservation rare in Holland, is one of the finest in the country. The grammar school was once attended by Erasmus.

SHERWIN, JOHN KEYSE (1751–1790), English engraver and historical painter, born in 1751 at East Dean in Sussex. His father was a wood-cutter employed in shaping bolts for shipbuilders, and the son followed the same occupation till his seventeenth year. He was befriended by William Mitford, upon whose estate the elder Sherwin worked, and was sent to study in London. He was first with John Astley, and then for three years under Bartolozzi—for whom he is believed to have executed a large portion of the plate of Clytie, after Annibal Caracci, published as the work of his master. He was entered as a student of the Royal Academy, and from 1774 till 1780 he was an exhibitor of chalk drawings and of engravings in the Royal Academy. Establishing himself in St. James's Street as a painter, designer and engraver, he began to mix in fashionable society. His drawing of the "Finding of Moses," introducing portraits of the princess royal of England and leading ladies of the aristocracy, hit the public taste, and sold largely. In 1785 he succeeded Woollett as engraver to the king, and he also held the appointment of engraver to the prince of Wales. He died on Sept. 20, 1790.

SHERWOOD, MARY MARTHA (1775–1851), English author, was born at Stanford, Worcestershire, on May 6, 1775, the daughter of the Rev. George Butt, D.D., then rector of Stanford. In 1803 she married her cousin, Captain Henry Sherwood, an officer in the British army, and subsequently accompanied him to India, where she devoted herself to charitable work and to writing. Her Indian story, *Little Henry and his Bearer,* was translated into many languages. Her best-known work, however, is *The History of the Fairchild Family* (3 pts. 1818, 1842 and 1847). Mrs. Sherwood wrote nearly a hundred stories of a religious type and tracts, mainly for the young. She died on Sept. 22, 1851.

See *The Life and Times of Mrs. Sherwood. From the Diaries of Captain and Mrs. Sherwood,* edited by F. J. H. Darton (1910).

SHERWOOD FOREST, one of the ancient English forests, in Nottinghamshire. It extended from Nottingham northward to Worksop, being over 20 m. long and from 5 to 9 m. broad. The soil is sandy and poor, and although a considerable portion has been brought under cultivation, the district preserves many traces of its ancient character. Sherwood was a crown forest from the time of Henry II. and a favourite hunting-ground of several kings; the land was divided between various lords of the manor, and its disafforestation was carried out at various times. The forest is traditionally noted as the retreat of Robin Hood. Considerable sections of the forest still remain, particularly near Mansfield, and around Rotherham and as parks at Wentworth and Wharncliffe.

SHETLAND or ZETLAND, a group of islands constituting a county of Scotland, and the most northerly British possession in Europe. It consists of an archipelago of more than 100 islands and islets, north-east of Orkney, between 59° 50′ and 60° 52′ N. and 0° 55′ and 2° 14′ W., and bounded on the west by the Atlantic and east by the North sea. The distance from Dennis head in North Ronaldshay of the Orkneys to Sumburgh head in Shetland is 50 m., but Fair Isle, which belongs to Shetland, lies midway between the groups. The islands occupy an area of 352,319 ac. (excluding water). Besides Mainland, the principal member of the group, the more important are Yell, Unst and Fetlar in the north, Whalsay and Bressay in the east, Trondra, East and West Burra, Papa Stour, Muckle Roe and Foula in the west, and Fair Isle in the south. The surface of the islands is irregular, frequently rising into considerable hills. Most of the scenery consists of treeless and barren tracts of peat and boulders, but the coast scenery is picturesque and grand, the cliffs, precipices of brilliant colouring, reaching a height over 1,000 ft. at some places. The shores are so extensively indented with *voes*, or firths—the result partly of denudation and partly caused by glaciers—that no spot in Shetland is more than 3 m. from the sea. There are freshwater lochs in the larger islands and numerous short streams. The principal capes are Sumburgh head, the most southerly point of Mainland; and Fitful head, on the south-west of the same island, 2 m. in length and nearly 1,000 ft. high, where Norna, the prophetess of Sir Walter Scott's *Pirate,* was supposed to have her abode and which the Norsemen called the White Mountain, from the colour of the clay slate composing it.

The geological character of the islands resembles that of northern Scotland. Old Red Sandstone, red grits, sandstones and marls and conglomerate occur in a narrow belt on the east side of Mainland and form the island of Bressay. In the western portion of Mainland there is a considerable tract of rocks of this age which are formed largely of intrusive diabase-porphyrite; similar volcanic rocks occur in Papa Stour. These are penetrated by granitic and felsitic intrusions; one of these masses in Papa Stour is a handsome pink felsite. Practically all the remainder of the islands is occupied by metamorphic schists and gneisses with which are associated dikes and masses of intrusive igneous rock.

History and Antiquities.—The word Shetland is supposed to be simply a modernized rendering of the Old Norse *Hjaltland,* of which the meaning is probably "high land." Of the prehistoric inhabitants remains exist in the form of stone circles (three in Unst and two in Fetlar) and *brochs* (of which 75 examples survive). The islanders were converted to Christianity in the 6th and 7th centuries by Irish missionaries, in commemoration of whose zeal several isles bear the name of Papa or "priest." Four stones with Ogam inscriptions have been found at different places. About the end of the 8th century both the Shetlands and Orkneys suffered from the depredations of Norse vikings, or pirates, until Harold Haarfager annexed the islands to Norway in 875. Henceforward the history of Shetland is scarcely separable from that of Orkney (*q.v.*). The people, more remote and less accessible to external influences, retained their Scandinavian characteristics longer than the Orcadians. The Norse language and customs survived in Foula till the end of the 18th century, and phrases of Norse origin still colour the speech.

Agriculture and Industries.—In spite of adverse climatic conditions, live stock is reared with a fair amount of success. The well-known Shetland breed of shaggy ponies is in steady demand. The native cattle, also diminutive in size, furnish fine beef and milk. The native sheep possess many of the characteristics of goats. Their wool is long and fine. It is customary to pluck the wool by hand rather than shear it. Black-faced and Cheviots are also found in some places. Large numbers of poultry and small pigs are kept. The lochs and tarns are well stocked with brown trout, and the voes and *gios,* or narrow inlets of the sea with steep rocks on both sides, abound with sea trout. Whales of various species are frequently captured in the bays and sounds, and whaling is carried on from a base on Olna firth, on Mainland. The grampus, dolphin and porpoise haunt the coasts, and seals are caught. There is an immense variety of water-fowl.

There has been no agricultural advance corresponding to that which has taken place in Orkney, mainly owing to the poverty of the soil. The majority of holdings are small crofts occupied mostly by peasants who combine fishing with farming. Crofting agriculture is conducted on primitive methods. There are over 1,700 crofts of under five acres, but the average holding is about eight acres. Only about one-fourteenth of the total area is under cultivation, oats and barley being the chief grain, and potatoes and turnips the chief green crops.

The distinctive manufacture is knitted goods of very delicate workmanship. The finest work is said to come from Unst, though each parish has its own speciality. Women do most of the farm work and spend their spare time in knitting. There is considerable trade in hand-woven, undyed tweeds. Fishing is the occupation of the men, and the real mainstay of the inhabitants. Formerly the fishery was completely in the hands of the Dutch, whose supremacy was destroyed, however, by the imposition of the salt tax in 1712. Then the fishery was neglected by the natives, who were content to use the "sixerns," or six-oared fishing boats, till the last quarter of the 19th century, when boats of modern type were introduced. Since 1890 the herring fishery has advanced rapidly, and the Shetland fishery district is now the most important in Scotland. The haaf or deep-sea catch principally consist of cod, ling and sethe or coalfish. Herrings are cured at Lerwick, on Unst, and at several other fishing stations. Communication with the islands is maintained by steamers from Leith and Aberdeen to Lerwick, the capital, Scalloway and other points.

Population.—In 1931 the population was 21,410, the females being in the high proportion of 124 to every 100 males. In 1931 there were 33 persons speaking Gaelic and English and none who spoke Gaelic only. The population has steadily declined since 1861, when it was 31,670. Only 24 islands of the group are inhabited, and in the case of some of them the population consists solely of a few lighthouse attendants, shepherds and keepers. The bulk of the inhabited islands are situated off the east and west coast of Mainland, two of them being outlying members of the group. From south to north they are as follows (the figures indicating the population in 1921). Fair Isle (127) lies 24 m. south-west of Sumburgh head, and is 3 m. long by about 2 m. broad. It has rocky cliffs, and North Haven, on the east coast, is almost the only place where landing can be safely effected. From the survivors of a vessel of the Spanish Armada the natives are said to have acquired the art of knitting the coloured goods for which they are noted. Mainland (18,268), the largest island, is 54 m. long and 21 m. wide, though the bulk of the island is much narrower than the extreme width would indicate.

In the promontory of Eshaness may be seen some wonderful examples of sea sculpture. The Grind of the Navir ("Gate of the Giants") is a staircase carved by the waves out of the porphyry cliffs. In the rock of Dore Holm is a natural archway, 70 ft. wide, and to the south-east of it are the Drougs, stacks of quaint shapes. Besides Lerwick (*q.v.*) the county town, one of the most interesting places in the island is Scalloway, the ancient capital, which stands at the head of a bay and has a pier, quays, warehouses and cooperages in connection with the fishing industry. The ruins of the castle built in 1600 by Patrick Stewart, earl of Orkney, stand at the east end of the bay. On the opposite side of the bay is Gallow hill, the old place of execution of witches and criminals. The *ting,* or open-air law court, assembled in former days on an island in the Loch of Tingwall (hence its

name), about 3 m. farther north. Off the south-eastern coast of Mainland, separated by a sound 1 m. broad and usually visited from Sandwick, lies the uninhabited island of Mousa, famous for the most perfect specimen of a Pictish *broch,* or tower of defence, in the British Isles. Hevera (28) lies off the west coast of Mainland, south of the two Burras. East Burra (169), about 4 m. long by 1 m. broad, is separated from Mainland by Clift sound, a narrow arm of the sea. West Burra (609), 6 m. long by 1 m. broad, with a very irregular coast-line, lies alongside of East Burra and contains a church. It is said to be the Burgh Westra of Sir Walter Scott's *Pirate.* Trondra (105), "Trond's island," is in the mouth of Scalloway bay. Bressay (583), 6 m. long by 3 m. broad, lies 1 m. E. of Lerwick, from which it is separated by the sound of Bressay, in which Haakon V., king of Norway, anchored his galleys on the expedition that ended disastrously at Largs (1,263). Ward Hill (742 ft.) is the sailors' landmark for Lerwick harbour. Bard head, the most southerly point, a haunt of eagles, has an archway at its foot, and on the west side the Orkney Man's cave—a great cavern with fine stalactites and a remarkable echo. Noss (6) is to the east of Bressay, from which it is separated by a channel 220 yds. wide. On the east coast the rocks form a headland called the Noup of Noss ("the peak of the nose"). Off the south-east shore lies the Holm, with which communication used to be maintained by means of the Cradle of Noss swing or ropes. Noss is utilized in connection with the rearing of Shetland ponies. Holm of Papal, "isle of the priest" (2), belonging to Bressay parish, lies south-east of Hildasay. Foula (149), 3½ m. long by 2½ m. broad, lies 27 m. W. of Scalloway, and 16 m. W. of the nearest point of Mainland.

The cliffs on its west coast are the home of myriads of seabirds and one of the nesting-places of the bonxie, or great skua. The natives are daring cragsmen. The only landing-place is the village of Ham, on the east coast. Vaila (10), in the mouth of the Bay of Walls, affords good pasturage. Papa Stour (119), "the big island of the priests," lies in the south-west of the great bay of St. Magnus. It is 2 m. by 3 m. and has very fine caves. Four miles north-west are the islets known as the Ve Skerries, where seals are found. Whalsay, "whale island" (855), 5 m. by 2½ m., is an important fishing station. Muckle Roe, "great red island" (189), roughly circular in shape and about 3 m. in diameter, lies in the east of St. Magnus bay. Grunay, "green isle" (9), Housay (72), Bruray (44), Bound (2) are members of the group of Out Skerries, about 4 m. N.E. of Whalsay. Yell (2,129), separated from the north-east coast of Mainland by Yell sound, is the second largest island of the group (17 m. by 6 m.), though towards the middle the voes of Mid Yell and Whale Firth almost divide it into two. It contains several *brochs* and ruined chapels and is a fishing station. Fetlar (224) lies off the east coast of Yell, from which it is divided by Colgrave sound and the isle of Hascosay (4) and is 5 m. by 6½ m. Uyea (9) lies south of Unst, from which it is divided by the narrow sounds of Uyea and Skuda. Unst (1,805), to the north-east of Yell and separated from it by Bluemull sound, is 12 m. by 6 m. It has been called the "garden of Shetland," and offers inducements to sportsmen in its trout and game. Near the south-eastern promontory stands Muness castle, now in ruins. Buness, near Balta sound, was the house of Dr. Laurence Edmonston (1795–1879), the naturalist. Near Balliasta are the remains of three stone circles. It is supposed the *ting,* or old Assembly, met at this spot before it removed to Tingwall. Farther north lies Haroldswick, where Harold Haarfager is believed to have landed in 872, when he annexed the Orkney and Shetland islands to Norway. Burra firth, in the north of Unst, is flanked by a series of magnificent cliffs. Muckle Flugga (3), which is situated about one mile north of Unst, is the extreme northernmost point of Shetland, and has long been the site of a lighthouse.

Shetland unites with Orkney to return a member to parliament. The island is divided into Mainland district and North Isles district. It forms a sheriffdom with Orkney and Caithness, and there is a resident sheriff-substitute at Lerwick, the county town. The county is under school board jurisdiction and Lerwick has a secondary school.

SHEVKET, MAHMUD (1858–1913), Turkish pasha. From 1901 to 1903 he was military governor of the Hejaz, in Arabia, then in what amounted to a state of war. He next went in a like capacity to Uskub (Skoplje), and there came in contact with the Young Turk movement, which had its headquarters in Salonika. In the spring of 1909 the Old and Young Turks were struggling for supremacy. A powerful Old Turk counter-revolution was prepared, but, in mid-April, the III. Army Corps, under Hussein Husni Pasha, marched from Salonika against Constantinople. At San Stefano Mahmud Shevket took over the command, and, after heavy fighting, on April 4 entered Constantinople.

Impressed by his victory, the National Assembly no longer dared to oppose the will of the Young Turks, and on April 26 voted the deposition of Abdul Hamid. Mahmud Shevket was the hero of the day. But he did not care for politics, which he considered had been the ruin of the Turkish corps of officers, and preferred to confine his activities to purely military matters. The next few years afforded him plenty of opportunities. In 1910–11 he put down a revolt of the Malissors with great energy, and in 1912 fought against the rebels in Albania. In the summer of 1912 he became minister of war, and in Jan. 1913 succeeded Kiamil as grand vizier. He took a very active part in army reforms, but he came into conflict with the Union Libérale, which took its orders from Sherif Pasha in Paris, and he was murdered by one of its members on June 11, 1913.

SHIAHS (SHIITES): *see* ISLAM.

SHIBARGHAN, a town and khanate of Afghan Turkestan. The town lies some 60 m. W. of Balkh. It has a citadel, but is not otherwise fortified, and is surrounded by good gardens and excellent cultivation. The khanate was allotted to the Afghans by the Anglo-Russian boundary agreement of 1873.

SHIBBOLETH, a Hebrew word meaning an ear of corn or a stream or river, used by Jephthah, probably in the second sense with reference to the river Jordan, as a test-word to distinguish the Ephraimites, who were unable to pronounce the *sh,* from the men of Gilead, at the passage of the Jordan (Judges xii.). The word *ciceri* was similarly used in the massacre of the French known as the Sicilian Vespers, and other "shibboleths" are known to history. The term is used of a watchword, catchphrase or cry, to which the members of the party adhere even after any significance which it may have had has disappeared.

SHIDEHARA, BARON (1872–), Japanese diplomat and statesman. He graduated in law at the Imperial university of Tokyo in 1895, and entered the diplomatic service in the following year. He was appointed Japanese minister to Holland in 1914, vice-minister for foreign affairs in 1915, and ambassador to the United States in 1919. He was created baron in 1920, and was one of the delegates to the Washington Conference in 1921–1922. He became minister for foreign affairs in the Kato Cabinet in 1924, and remained in his post until 1927.

SHIEL, LOCH, a lake near the Atlantic seaboard of Scotland, lying between the district of Moidart in Inverness-shire and the districts of Ardgour and Sunart in Argyllshire. The boundary line between the two counties is continued down the river Shiel to the sea. The loch is 17½ m. long and varies in width from 200 yd. to 1 m., and is only 11½ ft. above the sea. The maximum depth is 420 ft. with a mean depth of 81½ ft. Loch Dilate lies 1½ m. E. of Loch Shiel, into which it flows by the Polloch. It is 1½ m. long at its maximum, with a maximum depth of 55 ft. For fully three-fourths of its length Loch Shiel has a south-westerly direction, but at Eilean Fhianain (Finnan's island) it strikes towards the west. It receives the Finnan and other small streams and discharges by the Shiel to the salt-water Loch Moidart. On the north-west and south-east it is skirted by lofty hills, but the land at the western extremity in Ardnamurchan is low.

SHIELD-FERN, the name applied to ferns of the genus *Dryopteris* (called by some botanists *Aspidium* or *Thelypteris*), embracing, when regarded in a broadly inclusive sense, about 1,000 species, widely distributed throughout the world. The name is given because of the conspicuous shield-shaped indusia which, in many species, cover the spore-producing structures (*sporangia*) borne on the under surface of the fronds.

SHIELDS, FREDERIC JAMES (1833–1911), British painter and decorative artist, was born at Hartlepool, Durham, England, on March 14, 1833, the son of a bookbinder and printer. He was educated at the charity school of St. Clement Danes, and after drawing from the antique for a few months at the British Museum (1847), worked with firms of lithographers in London, Manchester and Halifax (1856). From 1867–75 he lived at Manchester, but after touring Italy settled in London in 1876. He was associated for many years with Brown, and with Rossetti, whose memorial window in the church at Birchington he designed. In 1896 he moved to Wimbledon, where he died on Feb. 26, 1911.

The oil painting and decorative designs to which he devoted himself in his later years were less suited to his talents than his earlier illustrative work (*e.g.*, the *Pilgrim's Progress* and Defoe's *Journal of the Plague Year*). He designed (1875–80) the stained glass and mosaic decoration for the duke of Westminster's chapel at Eaton, and (1887) the decoration for St. Luke's church, Camberwell. The decoration of the Chapel of the Ascension, Bayswater road occupied the last 20 years of his life. Exhibitions of Shields' work were held at the Brazenose club, Manchester (May, 1889), and at the Alpine club gallery (Oct., 1911).

See Mrs. Ernestine Mills, *Life and Letters of Frederic Shields* (1912).

SHIFNAL or **SHIFFNAL,** a market town of Shropshire, England, 17 m. E.S.E. of Shrewsbury on G.W.R. Pop. of parish (1921), 3,303. The church of St. Andrew is cruciform and full of fine details of late Norman, Early English and Decorated work. Trade is mainly agricultural, and cattle-fairs are held. The name of the town was Idsall when in 1591 a fund was raised by royal favour to rebuild it after a fire.

Within 6 m. E. of Shifnal are Tong, Boscobel and the nunnery of Whiteladies. Charles II. was concealed in the mansion of Boscobel in 1651. Whiteladies was a Cistercian nunnery. The surrounding wooded district was formerly part of Brewood Forest, which extended into Staffordshire. Rural dist. pop. (1931) 7,707.

SHIGATSE, one of the largest towns in Tibet, next in importance to Lhasa, the capital. The town, which is near the confluence of the Nyang Chu with the Tsangpo, contains about 9,000 inhabitants (exclusive of priests) and is about $\frac{3}{4}$ m. long and $\frac{1}{2}$ m. broad. It is an important station on the trade route up the Tsangpo from Lhasa, Batang and the east to Gartok. (*See* Tibet.) About 1 m. to the north-east is a monastery known as Konkaling, whilst to the south-west is the far-famed Tashi lhünpo monastery, the head of which, since the 17th century, has been second only to the Dalai-Lama, and is considered by some Tibetans to have even greater spiritual authority, though not temporal power. Between the Tashi lhünpo monastery and the city is the Thom, or open market, where all the business of the city is daily transacted. A wall about 1 m. in circumference surrounds the Tashi lhünpo monastery, within which are many temples and houses, four of the larger temples being decorated with gilded spires. A wealth of jewels and precious metals is said to enrich the images of Tashi lhünpo. There are about 3,300 priests. The city is protected by a fort, which stands on a low hill to the north-west. The municipal government is in the hands of two dēpen, assisted by resident Jongpons, who also watch the activities of the Tashi-Lama in the interests of the Dalai-Lama. The soil in the neighbourhood of Shigatse is rich and productive, and the elevation is between 11,000 and 12,000 feet.

SHIGNAN and **ROSHAN,** two small hill states east of the Badakshan province of Afghanistan. They extend eastwards from the Panja, where it forms the eastern boundary of Badakshan to the Pamirs. The native rulers of Roshan and Shignan claim descent from Alexander the Great, of whom legends are still current in the country about the upper Oxus. The two states were conquered by Abdur Rahman in 1882, but were assigned to Russia by the Durand agreement of 1893. Since that agreement Russia has retired from all districts previously occupied by her on the left bank of the Panja, or upper Oxus. Under Soviet rule they form a portion of one of several Soviet republics that border the Oxus.

SHIKAR, a hunting and shooting term used by anglo-Indians to denote game; it may also be used in a general sense for sport. The sportsman is called a shikari. (*See* Big Game and Shooting.)

SHIKARPUR, a town of British India, in the Sukkur district of Sind, Bombay. It is situated about 18 m. from the right bank of the Indus, with a station on the North-Western railway, 23 m. N.W. of Sukkur. Pop. (1921), 55,503. Shikarpur has been an important place in the past as commanding the trade route through the Bolan pass, and its merchants have dealings with many towns in Central Asia. Shikarpur was formerly the headquarters of a district of the same name. In 1901 two subdivisions of this district were detached to form the new district of Larkana, and the two other subdivisions were then formed into the district of Sukkur. The railway link between Baluchistan and Sukkur has seriously reduced the importance of Shikarpur in recent years, but the town retains its old trade in silks and precious stones.

SHILDON, town, Durham, England, 9 m. north-west from Darlington on the L.N.E.R. Pop. of urban district of Shildon and East Thickley (1931) 12,690. At New Shildon or East Thickley are extensive railway engine and wagon works.

SHILLING. An English silver coin of the value of 12 pence. The origin of the word is somewhat obscure. There was an Anglo-Saxon coin termed *scilling,* or *scylling,* worth about fivepence, which is said to be derived from a Teutonic root, *skil,* to divide, + *ling* on the analogy of farthing (*q.v.*). The silver shilling was first struck in 1504, in the reign of Henry VII. In Charles II.'s reign shillings were first issued with milled edges. In George IV.'s reign were issued the so-called "lion shillings," bearing the royal crest, a crowned lion on a crown, a design reverted to in the coinage of Edward VII. A shilling is token money merely; it is nominally in value one-twentieth of a pound, but one troy pound of silver is coined into 66 shillings. (*See* Token Money.) The shilling is equal to 24 cents, United States currency.

SHILLONG, a town of British India, the capital of Assam and the headquarters of the Khasi Hills district. It is situated on a plateau 4,978 ft. above the sea, 63 m. by cart-road S. of Gauhati, on the Brahmaputra. Pop. (1921) 17,203. Shillong practically dates from 1864, when the district headquarters were transferred from Cherrapunji. It was chosen as the seat of government in 1874, when the province of Assam was constituted. It contains a cantonment, Pasteur institute and research laboratory (for anti-rabies treatment), and schools for the education of European and Eurasian boys and girls. Its pleasant climate and delightful surroundings make Shillong a popular health and holiday resort. Every one of the public buildings and houses was levelled to the ground by the great earthquake of June 12, 1897, but they have since been rebuilt.

SHILLUH, the name given by the Arabized Moors to the Berber peoples of southern Morocco. They occupy chiefly the province of Sus. The name is said to be a corruption of *áshlūh* (pl. *íshlúh*), a camel-hair tent. They are of fine physique, strong and wiry, and true Berbers in features and fairness.

SHILLUK: *see* Nilotes.

SHILOH, a town of Ephraim, where for three centuries after the Israelite conquest of the Holy Land it was the depository of the Tabernacle and Ark of the Covenant. In its sanctuary the boy Samuel had his vision. With the removal of the Ark Shiloh's glory departed and by the time of Jeremiah (vii. 12) it was a heap of ruins. Its identification with the modern Seilūn, 2 m. S.E. of El-Lubbān (Lebonah) on an isolated hill affording an ideal site for a sanctuary and fortress, is not disputed. (E. Ro.)

SHILOH, BATTLE OF. This, the second great battle in the American Civil War, also called the battle of Pittsburgh Landing, was fought on April 6 and 7, 1862, between the Union forces under Grant and Buell and the Confederates under A. S. Johnston and Beauregard. In view of operations against Corinth, Mississippi, Grant's army had ascended the Tennessee to Pittsburgh Landing and there disembarked, while the co-operating army under Buell moved across country from Nashville to join it. The Confederates concentrated 40,000 men at Corinth and advanced on Pittsburg Landing with a view to beating Grant before Buell's arrival, but their concentration had left them only a narrow margin of time, and the advance was further delayed by the wretched

condition of the roads. Beauregard advised Johnston to give up the enterprise, but on account of the bad effect a retreat would have on his raw troops Johnston resolved to continue his advance. Grant meantime had disposed his divisions in camps around the Landing rather with a view to their comfort than in accordance with any tactical scheme. No entrenchments were made; Halleck, the Union commanding general in the West, was equally overconfident, and allowed Buell to march in leisurely fashion. Even so, more by chance than intentionally, Buell's leading division was opposite Savannah 9m. below the Landing, awaiting only a ferry, on the evening before the battle; Grant, however, declined to allow it to cross, as he thought that there would be no fighting for some days. At 6 A.M. on April 6, near Shiloh church (2m. from Pittsburgh Landing), the Confederate army deployed in line of battle, and advancing directly on the Landing, surprised and broke up a brigade of the most advanced Union division (Prentiss's) which had been sent forward from camp to reconnoitre. The various Union divisions hurriedly prepared to defend themselves, but they were dispersed in several camps which were out of sight of one another, and thus the Confederate army lapped round the flanks of each local defence as it encountered it. The two advanced divisions were swiftly driven in on the others, who were given a little time to prepare themselves by the fact that in the woods the Confederate leaders were unable to control or manoeuvre their excited troops. But the rear Union divisions, though ready, were not connected, and each in turn was isolated and forced back, fighting hard, towards the Landing. The remnant of Prentiss's division was cut off and forced to surrender. Another division had its commander, W. H. L. Wallace, killed. But on the other side the disorder became greater and greater, many regiments were used up, and Johnston himself killed in vainly attacking on a point of Wallace's line called the Hornet's Nest. The day passed in confused and savage scuffles between the raw enthusiasts of either side, but by 5:30 P.M. Grant had formed a last (and now a connected) line of defence with one brigade of Buell's leading division (Nelson's) and all of his own infantry that he could rally. This line was hardly 600yd. from the Landing, but it was in a naturally strong position, and Beauregard suspended the attack at sunset. There was a last fruitless assault, delivered by some of the Confederate brigades on the right that had not received Beauregard's order against Nelson's intact troops, who were supported by the fire of the gunboats on the Tennessee. During the night Grant's detached division (Lew Wallace's) and Buell's army came up, totalling 25,000 fresh troops, and at 5 A.M. on the 7th Grant took the offensive. Beauregard thereupon decided to extricate his sorely-tried troops from the misadventure, and retired fighting on Corinth. About Shiloh church, a strong rear-guard under Bragg repulsed the attacks of Grant and Buell for six hours before withdrawing, and all that Grant and Buell achieved was the reoccupation of the abandoned camps. It was a Confederate failure, but not a Union victory, and, each side being weakened by about 10,000 men, neither made any movements for the next three weeks.

See F. A. Shoup, "The Art of War in '62—Shiloh," *United Service*, ser. 3, vol. viii., p. 67–80 (1905); and S. M. Howard, *The Illustrated Comprehensive History of the Great Battle of Shiloh* (Gettysburg, S.D., 1921).

SHIMOGA, a town and district in Mysore, southern India. The town is situated on the Tunga river, and is the terminus of a branch railway. It has cotton ginning and pressing factories and iron and steel works. Pop. (1921) 15,090. The area of the district is 4,030 sq.m. In the east the Tunga, Bhadra and Varada rivers unite to form the Tungabhadra, which ultimately falls into the Kistna and so into the Bay of Bengal, while in the west a few minor streams flow to the Sharavati, which near the north-western frontier bursts through the Western Ghats at the celebrated Falls of Gersoppa (*q.v.*).

The western half of the district is mountainous and covered with magnificent forest, and is known as the Malnad or hill country, some of the peaks being 4,000 ft. above sea-level. The general elevation of Shimoga is about 2,000 ft.; and towards the east it opens out into the Maidan or plain country, which forms part of the general plateau of Mysore. Manganese is worked. The soil is loose and sandy in the valleys of the Malnad, and in the north-east the black cotton soil prevails. Shimoga presents much variety of climate. The south-west monsoon is felt in full force for about 25 m. from the Ghats, but the rainfall gradually diminishes to 31 in. at Shimoga station and to 25 in. or less at Chennagiri. The population in 1921 was 492,560. Rice is the staple crop; next in importance is sugar-cane; areca nuts are also extensively grown; and miscellaneous crops include vegetables, fruits, and pepper. The mineral products of the district include iron-ore and laterite.

SHINGLES. The popular name for the variety of herpes (*q.v.*) known as herpes zoster, from its tendency to extend in girdle fashion around the waist, *i.e.*, one or both sides of the chest. The rash of shingles in itself is but moderately painful, but the importance of the condition lies in the hyperaesthesia of the skin in neighboring parts supplied by the same nerve. This hyperaesthesia is such that the slightest touch causes a burning pain resembling that occasioned by touching a raw and highly sensitive surface. Associated with the pain due to the eruption are muscular and joint pains (possibly resulting from the enforced immobilization of the part) and these, in the form of cramps, may be even more severe than the superficial pain. As a result of such paroxysms of pain, sleep is interfered with, often to an important extent, and the patient looks tired and worried. Nevertheless, he is not ill as with an acute infective illness, though the temperature may be raised a little at times. Paroxysms of pain are often determined by extraneous causes, *e.g.*, in the case of herpes of the thigh by a full rectum, hunger, insufficient or excessive warmth. The real importance of the disease lies in the fact that the pain is often so severe that there is a danger that recourse may be made to morphia for its relief. In view of the duration of the associated neuralgic pain, the danger of inducing the morphia habit is very great, and use of morphia and other opiates must be avoided at all costs. Though distressing, the disease is never fatal, in spite of the popular belief that such is the case if the shingles extend right round the body. There is a relation between shingles and chicken-pox, for the two are apt to be associated in the same community and may even occur in the same individual simultaneously.

SHINTŌISM. Shintō or *"Kami-no-Michi"* (the Divine Way), the religion of Japan, still living among the Japanese people, is a designation given to the early religious belief of the Japanese soon after their first contacts with China. The first documentary appearance of the term Shintō is in the Book of the Emperor Yōmei in the *Nihongi* (Aston, Eng. trans., vol. i., p. 106).

Shintō has two main stages in the course of its development: one is naturalistic, the other cultural. In the two phases of its development, the one gives us an aspect of nature religion, while the other presents that of ethico-intellectualistic (or spiritualistic) religion, greatly influenced by Buddhism and Confucianism.

Nature Religion.—In Shintō as a lower nature religion we find nature worship, fetishism, spiritism, totemism and primitive monotheism. The primitive Japanese worshipped the sun, the moon, the rainstorm, thunder, wind and fire; earth, the sea, the mountain, the deity of the earthquake, volcanoes, wells, hot springs and stones or rocks; the serpent, the tiger, the wolf, the wild boar, the hare, even the silkworm and the louse, trees, herbs and cereals.

Anthropolatry.—Individual personages are also worshipped as *Kami* or deities in their lifetime as well as after their death, and we have Shintō shrines dedicated to special divine personages while living. The emperor is regarded as a "Visible Deity" (*Arahitogami* or *Akitsukami*), and some brave warriors or mighty heroes are also deities in human form. Later on the Ryōbu or Dual Shintō made good use of this form of religious syncretism. There is quite a number of examples of necrolatry and ancestor worship in Shintō. The sacred imperial regalia (or heirlooms), consisting of the mirror, sword and jewels, had originally a fetishistic virtue.

Litholatry, etc.—Particularly in Japan, sacred stones are regarded as fetishes (litholatry). Different phallic emblems of stone or wood, both male and female in shape, are not very uncom-

mon (phallicism). There is some evidence of totemism in primitive Shintō; *e.g.,* Kamo-Taketsunumi-no-Mikoto, the remote ancestor of the Shintō priests of the Kamo Shrine in Kyōto, was once believed to be a large divine crow, afterwards worshipped at a separate shrine. The father of the Emperor Jimmu was traditionally recorded to have sprung from the crocodile or dragon Sea-Goddess Toyotama-Hime, the consort of Hikohohodemi-no-Mikoto.

There is something like a primitive monotheism in Ame-no-Minakanushi-no-Kami, or the Divine Lord of the Very Centre of Heaven, amalgamated with another supreme deity, Kunitokotachi-no-Kami, in later Shintō.

Mythology.—Primitive Shintō appears as a higher nature religion in the heavenly drama of the rich mythology of the *Kojiki* (*Records of Ancient Matters*), the *Nihongi* (*Chronicles of Japan*) and the *Kogoshui* (*Gleanings from Ancient Stories*). A conflict between the sun and the rainstorm was graphically delineated in Japanese mythology as a momentous event in the Divine Age. Then a divine council was held to entreat the Sun-Goddess to restore peace and order to the world and to reilluminate it by emerging from the heavenly rock-cave in which she had taken refuge from the violence committed by the impetuous brother Susano-O-no-Kami. Then follows the banishment of the divine culprit Susano-O from heaven to earth.

Emperor Worship.—Then according to tradition, half mythical, half historical, the Japanese imperial lineage has continued unbroken from the Ancestral Sun-Goddess to the present emperor, who, like his predecessors, enjoys a divine right to the throne, representing in himself both Caesar and pope—as a divinity in humanity. Even nowadays, in the hierarchy of his theocratic as well as constitutional government, he is often phrased "saiseiitchi," or the complete unity of political governance and religious observances. Thus Shintō as a national or state religion culminates in the form of emperor worship, not only in its naturalistic but also in its ethico-intellectualistic stage. Therefore Japanese patriotism or loyalty has been suffused with religious zeal. Herein lies one of the peculiar characteristics of the life or essence of Shintō.

As to the course of development of Shintō in its cultural stage, it is polydemonistic (animistic) at the beginning, then polytheistic, and at last pantheistic, with a tinge of monotheism.

Such a naturalistic pantheism of Shintō is deepened and ennobled by a further idealistic or spiritualistic grasp of the Shintō-Deity. Hayashi-Razan, an eminent scholar of Chinese classics of the 17th century says: "The Deity is the Spirit of Heaven and Earth. The human mind partaking of divinity is an abode of the Deity, which is the Spiritual Essence. There exists no highest deity Ame-no-Minakanushi-no-Kami outside the human mind" (*Shintō-Denju*).

SHINWARI, a Durrani Afghan tribe occupying the northern slopes of the Safed Koh below Jalalabad. One clan, the Ali Sher Khel, live on the Doargai border of Peshawar district. The remaining three clans are Afghan subjects.

SHIP, the vehicle by which man conveys himself and his goods upon water. The earliest and most elementary form of ship was, doubtless, a log or one or two of them secured together to form a raft. The first conception of a vessel which can carry weights, not merely on account of its own buoyancy, but on account of the water it displaces, may be traced in the primitive craft fashioned by hollowing out tree trunks, by fire or such primitive tools as savage races could devise.

It was long before the principle of flotation by displacement was fully and universally understood, and we read of objectors to the introduction of iron ship construction arguing that "wood floats but iron sinks," yet it is this principle which makes possible the great ship as we know it to-day. Some glimmering of the future seems, however, to have enlightened Virgil when he wrote, "Rivers then first the hollowed alder felt" (Georg. i. 136, ii. 451). Alder is a heavy wood and not fit for rafts, but to make for the first time a dug-out canoe of alder, and so to secure its flotation, would be a triumph of primitive art.

PRIMITIVE CRAFT

Early efforts at shipbuilding may be classified in the following order: (1) rafts—floating logs, or bundles of brushwood of reeds or rushes tied together; (2) dug-outs—hollowed trees; (3) canoes of bark, or of skin stretched on framework or inflated skins (balsas); (4) canoes or boats of pieces of wood stitched or fastened together with sinews or thongs or fibres of vegetable growth; (5) vessels of planks, stitched or bolted together with inserted ribs and decks or half decks; (6) vessels of which the framework is first set up, and the planking of the hull nailed on to them subsequently. All these in their primitive forms have survived, in various parts of the world, with different modifications which mark a varied progress in civilization. On the northwest coast of Australia, for instance, is found the single log of buoyant wood, not hollowed out but pointed at the ends. Rafts of reeds are still used by the natives of the same continent. In New Guinea catamarans of three or more logs lashed together with rattan are commonly used, and similar forms appear on the Madras coast and throughout the Asiatic islands. On the coast of Peru rafts made of a very buoyant wood are in use, some of them as much as 70 ft. long and 20 ft. broad; these are navigated with a sail, and, by an ingenious system of centre boards, let down either fore or aft between the lines of the timbers, can be made to tack. The sea-going raft is often fitted with a platform so as to protect the goods and persons carried from the wash of the sea. Upright timbers fixed upon the logs forming the raft support a kind of deck, which in turn is itself fenced in and covered over. (The raft of Ulysses described in Homer [*Od.* v.] must have been of this class.) Thus the idea of a deck, and that of side planking to raise the freight above the level of the water and to save it from getting wet, are among the earliest typical expedients in the progress of the art of shipbuilding.

Dugout canoes of a single tree have been found associated with objects of the Stone Age among the ancient Swiss lake dwellings; other specimens have been extracted from the bogs of Ireland and the estuaries of England and Scotland. Whatever may have been the origin of the bark canoe, its construction was a step onwards in the art of shipbuilding, for the lightness and pliability of the material necessitated the invention of some internal framework. In those countries where suitable timber was not to be found, the use of skins or other water-tight material, such as felt or canvas, covered with pitch, giving flotation, demanded a similar framework to keep them distended and to bear the weight they had to carry. In this structure we have the rudimentary ship, with longitudinal bottom timbers, and ribs, and cross-pieces, imparting the requisite stiffness to the covering material. Bark canoes are found in Australia, but the American continent is their true home. In northern regions skin or woven material made water-tight supplies the place of bark.

The next step in the construction of vessels was the building up of canoes or boats by fastening pieces of wood together in a suitable form. Some of these canoes, and probably the earliest in type, are tied or stitched together with thongs or cords. The Madras surf boats are perhaps the most familiar example of this type, which, however, is found in the Straits of Magellan and in Central Africa (on the Victoria Nyanza), in the Malay Archipelago and in many islands of the Pacific. Some of these canoes show a great advance in the art of construction, being built up of pieces fitted together with ridges on their inner sides, through which the fastenings are passed. (*See* Captain Cook's account of the Friendly Islands, La Pérouse on Easter Island, and Williams on the Fiji Islands.) They achieved some of the advantages of a more elastic structure which gives ease in a seaway, and a comparative immunity where more rigid boats would not hold together. Vessels thus stitched together, and with an inserted framework, have from a very early time been constructed in the Eastern seas far exceeding in size anything that would be called a canoe, and in some cases attaining to 200 tons burthen.

From the stitched form the next step onwards is to fasten the

materials out of which the hull is built up by pegs or treenails; and of this system early types appear among the Polynesian islands and in the Nile boats, the prototype of the modern "nuggur." Some of the early types of boats belonging to the North Sea present an intermediate method, in which the planks are fastened together with pins or treenails, and are attached to the ribs by cords passing through holes in the ribs and corresponding holes bored through ledges cut on the inner side of each plank.

The ribs of the modern vessel are the development of the framework originally inserted after the completion of the hull of the canoe or built-up boat, but with the difference that they are now prior in the order of fabrication.

THE ROWING GALLEY

The earliest representations of Egyptian vessels carry us back to a period about 3,000 years before Christ. Some of these are of considerable size, as is shown by their twenty or more rowers, and by the cargo consisting in many cases of cattle. The earliest of all presents us with the peculiar mast of two pieces, stepped apart but joined at the top. In some the masts are shown lowered and laid along a high spar-deck. On the war galleys (*see* GALLEY) there is frequently shown a projecting bow with a metal head well above the water. This was doubtless used as a ram.

The double mast of the earlier period seems in time to have given place to the single mast furnished with bars or rollers at the upper part, for the purpose apparently of raising or lowering the yard according to the amount of sail required. The sail in some of the galleys is shown with a bottom as well as a top yard. In the war galleys during action it is shown pulled up like a curtain with loops to the upper yard. The steering was effected by paddles, sometimes four or five in number, but generally one or two fastened either at the end of the stern or at the side, and above attached in such a way as to be worked by a tiller.

The Egyptian ship as depicted by the tomb paintings, during the period between 3000 and 1000 B.C., was a ship proper as distinct from a large canoe or boat. It was, in fact, the earliest ship of which we have cognizance.

But credit for the further development of the ship and of the art of navigation clearly belongs to the Phoenicians. The earliest and almost the only evidence that we have of this development is to be gathered from Assyrian representations. The Assyrians were an inland people, and the navigation with which they were familiar was that of the two great rivers, Tigris and Euphrates, but after the conquest of Phoenicia we find that the war galley of the Phoenicians was represented on the walls of the palaces unearthed by Layard and his followers in Assyrian discovery. But the date does not carry us to an earlier period than 700 B.C. The vessel represented is a bireme war galley which is "aphract," that is to say, has the upper tier of rowers unprotected and exposed to view.

The Phoenicians at an early date constructed merchant vessels capable of carrying large cargoes, and of traversing the length and breadth of the Mediterranean. They in all probability (if not the Egyptians) invented the bireme and trireme, solving the problem by which increased oar-power and consequently speed could be obtained without great increase in length of the vessel.

Greek Vessels.—It is, however, to the Greeks that we must turn for any detailed account of these inventions. The Homeric vessels were "aphract" ("uncovered"), not even decked throughout their entire length. They carried crews of from fifty to a hundred and twenty men, who all took part in the labour of rowing, except perhaps the chiefs. The galleys do not appear to have been armed as yet with the beak, though later poets attribute this feature to the Homeric vessel. But they had great poles for use in fighting. The general characteristics are indicated by the epithets in use throughout the *Iliad* and the *Odyssey*. The Homeric ship was sharp and swift, hollow, black, vermilion-cheeked, dark-prowed, curved, well-timbered, with many thwarts. The stems and sterns were high, upraised, and resemble the horns of oxen. They presented a type of Mediterranean ship parallel with that of the Vikings' vessels of the North Sea.

The trireme was succeeded and in a measure superseded by the larger rates,—quadrireme, quinquereme, and so on, up to vessels of sixteen banks of oars. How these were arranged is the subject of much discussion and argument which cannot be dealt with in the compass of this article.

The terms "Aphract" and "Cataphract" meant "unfenced" and "fenced," and referred to the bulwarks which covered the upper tier of rowers from attack. In the aphract vessels these side plankings were absent and the upper tier of rowers was exposed to view from the side. Both classes of vessels had upper and lower decks, but the aphract class carried their decks on a lower level than the cataphract.

Early Construction.—As regards the construction of the vessel itself: in the cataphract class the lower deck was 1 ft. above the water-line. Below this deck was the hold, which contained a certain amount of ballast, and through an aperture in this deck the buckets for baling were worked, entailing a labour which was constant and severe on board an ancient ship at sea. The keel appears to have had considerable camber. Under it was a strong false keel, very necessary for vessels that were constantly drawn up on the shore. Above the keel was the kelson, under which the ribs were fastened. These were so arranged as to give the necessary intervals for the oar-ports above. Above the kelson lay the upper false keel, into which the mast was stepped. The stem rose from the keel at an angle of about 70° to the water. Within was an apron, which was a strong piece of timber curved and fitting to the end of the keel and beginning of the stern-post and firmly bolted into both, thus giving solidity to the bows, which had to bear the beak and sustain the shock of ramming. As steering was effected by means of two rudders, one on either side, there was no need to carry out the stern into a rudder post as with modern ships, and the stern was left, therefore, much more free, an advantage in respect of the manoeuvring of the ancient Greek man-of-war, the weapon being the beak or rostrum, and the power of turning quickly being of the highest importance.

After the ribs had been set up and covered in on both sides with planking, the sides of the vessel were further strengthened by waling-pieces carried from stern to stem and meeting in front of the stern-post. These were further strengthened with additional balks of timber, the lower waling-pieces meeting about the water-level and prolonged into a sharp three-toothed spur, of which the middle tooth was the longest. This was covered with hard metal (generally bronze) and formed the beak. The whole structure of the beak projected about 10 ft. beyond the stern-post. Above it, but projecting much less beyond the stern-post, was the "proembolion," or second beak, in which the prolongation of the upper set of waling-pieces met. This was generally fashioned into the figure of a ram's head, also covered with metal. Sometimes there was a second line of waling-pieces terminating in another boss. These bosses, when a vessel was rammed, completed the work of destruction begun by the sharp beak at the water-level, giving a racking blow which caused her to heel over and so eased her off the beak, releasing the latter before the weight of the sinking vessel could come upon it. At the point where the prolongation of the second and third waling-pieces began to converge inwards towards the stem on either side of the vessel stout catheads projected, which were of use, not only as supports for the anchors, but also as a means of inflicting damage on the upper part of an enemy's vessel, while protecting the side gangways of its own and the banks of oars that worked under them. The catheads were strengthened by strong balks of timber, which were firmly bolted to them under either extremity and both within and without, and ran to the ship's side. Above the curvature of the upper waling-pieces were the cheeks of the vessel, generally painted red, and in the upper part of these the eyes, answering to our hawse holes, through which ran the cables for the anchors. On either side the trireme, at about the level of the thranitic benches, projected a gangway resting against the ribs of the vessel. This gangway was planked in along its outer side so as to afford protection to the seamen and marines, who could pass along its whole length without impeding the rowers. Here, in action, the sailors were posted as light-armed troops, and when needed could use the

long supernumerary oars. The ribs, prolonged upwards upon an inward curve, supported on their upper ends the cross beams which tied the two sides of the vessel together and carried the deck. In the cataphract class these took the place of the thwarts which in the earlier vessels, at a lower level, yoked together the sides of the vessel, and formed also benches for the rowers to sit on. On the deck were stationed the marines, fighting men in heavy armour. The forecastle had a raised deck. In the stern the decks rose in two or three gradations, upon which was a kind of deck-house for the captain and a seat for the steerer, who steered by means of ropes attached to the tillers fixed in the upper part of the paddles, which, in later times at least, ran over wheels, giving him increased power. Behind the deck-house rose the flagstaff, on which was hoisted the pennant, and from which probably signals were given in the case of an admiral's ship. On either side of the deck ran a balustrade, which was covered for protection during action with felt or canvas. Above was stretched a strong awning of hide as a protection against grappling irons and missiles of all kinds.

All the Attic triremes appear to have been built upon the same model, and their gear was interchangeable. The Athenians had a peculiar system of girding the ships with long cables, each trireme having two or more, which, passing through eyeholes in front of the stern-post, ran all round the vessel lengthwise immediately under the waling-pieces. They were fastened at the stern and tightened up with levers. These cables by shrinking as soon as they were wet, tightened the whole fabric of the vessel, and in action, in all probability, relieved the hull from part of the shock of ramming, the strain of which would be sustained by the waling-pieces convergent in the beaks. These rope-girdles are not to be confused with the process of undergirding or frapping, such as is narrated of the vessel in which St. Paul was being carried to Italy. The trireme appears to have had two masts. In action the Greeks did not use sails, and everything that could be lowered was stowed below. The mainmasts and larger sails were often left ashore if a conflict was expected.

The crew of the Attic trireme consisted of from 200 to 225 men in all. Of these some 170 were rowers. Besides the rowers there were 10 marines and 20 seamen. The chief officer was the trierarch and next to him the helmsman, who was the navigating officer of the trireme. The economy of space was such that, as Cicero remarks, there was not room for one man more.

The improvement made in the build of their vessels by the Corinthian and Syracusan shipwrights, by which the bows were so much strengthened that they were able to meet the Athenian attack stem on, caused a change of tactics, and gave an impetus to the building of larger vessels—quadriremes and quinqueremes —in which increased oar-power was available for the propulsion of the heavier weights.

Roman Ships.—The Romans, who developed their naval power during the First Punic War, though it is clear from the treaty with Carthage, 509 B.C., that they had had some maritime interests and adventurings before that great struggle began, were deficient in the art of naval construction. A Carthaginian quinquereme, which had drifted ashore, served them for a model, and with crews taught to row in a framework set up on dry land they manned a fleet which was launched in sixty days from the time that the trees were felled. Their first attempt was, as might have been expected, a failure. But they persevered, and the invention of the "corvus," by means of which boarding was opposed to ramming tactics, gave them under Duilius (260 B.C.) victory at Mylae, and eventually the command of the sea. From that time onwards they continued to build ships of many banks, and seem to have maintained their predilection for fighting at close quarters. The larger vessels with their "turres," or castles, fore and aft, deserved Horace's description as "alta navium propugnacula." The "corvus" and the "dolphin" were ready in action to fall on the enemy's decks.

But the fashion of building big ships received a severe setback at the battle of Actium (31 B.C.), when the light Liburnian "biremes," eluding the heavy missiles of the larger vessels, swept away their banks of oars, leaving them crippled and unable to move, till one by one they were burnt down to the water's edge and sank. (Merivale, *Hist. of Romans under the Empire,* c. 28.) After this experience the Romans adopted the Liburnians as their principal model, and though the building of vessels with many banks continued for some centuries, yet the Liburnian type was so far dominant that the name was used generically to signify a man-of-war.

The building of large merchant vessels followed with more peaceful times. These craft were propelled by sails and not by oars. The great corn ships, which brought supplies from Egypt to the capital, were, if we may take the vessel described by Lucian as a typical instance, 120 cubits long by 30 broad and 29 deep. The ship in which St. Paul and his companions were wrecked carried 276 souls besides cargo. Even larger vessels than these were constructed by the Romans for the transport of marbles and great obelisks to Italy. Many of these vessels are reputed to have carried three masts, although the number is doubted by modern authorities. They had square sails, and on the main mast a topsail.

Meanwhile special vessels continued to be constructed for fighting purposes. In the war with the Vandals (A.D. 440–470) we hear of ships of a single bank, with decks above the rowers. These, we are told, were of the type which at a later date were called Dromons in allusion to their speedy qualities, a name which gradually superseded the Liburnian as indicating a man-of-war. During the following centuries the Mediterranean was the scene of constant naval activity. The necessity of improving galleys as regards speed and armament became more and more pressing. Greek fire and other detonating and combustible mixtures, launched by siphons or in the form of bombs, led to various devices by way of protective armour, such as leather or felt casing, or woollen stuffs soaked in vinegar.

Meanwhile the northern seas were breeding a new terror. The ships of the Vikings, propelled by oar and sail, were seagoing vessels of an excellent type. They were of various sizes, ranging from the *skuta* of about 30 oars to *ask* or *skeid* with 64 oars and a crew of 240, and to the still larger *dreki* or dragon boats, and the famous *snekkjur* or serpents, said to be represented on the Bayeux tapestry. Of these vessels we have fortunately a typical instance, though one of the smaller class, in the well-known Viking ship discovered in 1880 in a tomb-mound at Gokstad near Christiania (Oslo), whose dimensions are: length 78 ft., beam 16 ft. 7 in., depth 5 ft. 9 in., with high stem and stern; clinker-built of oak throughout, with 16 oars on either side. Of this general type were the vessels large and small which had by the 9th century or before that found their way into the Mediterranean. If, as is probable, the Danes who invaded England used the same class of vessel, Alfred the Great must, according to the *Saxon Chronicle,* be credited with improvements in construction, which enabled him to defeat them at sea (897). He built, we are told, vessels twice as long as those of the Danes, swifter, steadier and higher, some of them for 60 oars, and after his own design, not following either the Danish or Frisian types.

MEDIAEVAL SHIPS

The mediaeval galley was a one, two or three banked vessel, but used longer oars or sweeps than the paddling oars of the ancient vessels. It was the increase in the length and weight of the oar, which led to the employment of more than one man to an oar. With the longer oar the necessity arose of placing the weight at a greater distance from the power applying the lever. This was gained by the re-introduction of the *apostis,* which was practically a framework standing out on each side of the hull and running parallel to it; a strong external timber, in which the thowls, against which the oars were rowed, were set. By this means it became possible not only to arrange the oars horizontally, in sets of three or more of different lengths, instead of in banks one above the other obliquely, but also to apply the strength of three or four men (or even up to seven with the larger galleys and galleasses) for the motive power of each blade. As time went on oars of from 30 to 50 ft. came into vogue, the inboard portion of which was about one-third of the

length, and furnished with handles attached to the loom, the men for each oar being placed in steps. As commerce increased and merchant vessels gained in size, the necessity of being able to defend themselves against piratical attacks became more and more cogent, a necessity which ultimately led the way to the supersession of the galley by the sailing vessel.

The period of the Crusades was one of great activity in shipbuilding, in which the Venetians and the Genoese were the leaders in the Mediterranean, but the enterprise of England under Richard Coeur de Lion (1189–1199) shows that in the northern seas great efforts were being made in the same direction. Richard's fleet which sailed from Dartmouth consisted of 110 vessels, and its total in the Mediterranean after reinforcement was 230 vessels.

The whole period of the Crusades was, as regards naval matters, one of mixed fleets, in which the sailing vessels were mostly merchant vessels armed for fighting purposes. About this time we see the steering oar on the side of the ship gradually disappear, and the rudder slung at the stern becoming the usual means of directing the vessel's course. The advantage of high freeboard for longer voyages was appreciated. It was in northern waters that the big merchantman was most rapidly developed, as the needs of the merchants outgrew the armed galleys that had been brought to a high pitch of perfection by the Venetians and Genoese, and chartered by them nearly all over Europe. In the Mediterranean many features of this type were combined with those of the galley and produced the carrack of Genoa and the galleasse. The merchant vessels when prepared for war had forecastles and stern-castles erected on them, of which the one survives in name, and the other is seen in the poop of later times.

The invention of gunpowder, and the consequent use of cannon on board ship, was the cause of many new departures in building and armaments. In the galleys we find guns mounted in the bows, and broadside on the upper deck, *en barbette,* firing over the bulwarks. Soon, however, the need of cover suggested portholes cut for the guns, just as in the ancient galleys they had been cut for the oars. The desire to carry many guns led to many alterations in build, such as the tumble-home of the sides, the longer voyages undertaken, coupled with the desire for speed, to many improvements in rig, as well as to an increase in the number of masts and consequently larger spread of sail. About 1370–1380 French, Venetians and Spaniards were using the new artillery in action, and the policy of maintaining a navy composed of sailing vessels built for war, and not merely of armed merchant ships impressed for the emergency, soon began to take effect. There exists at Nuremberg an engraving believed to have been taken from a model of a 15th-century Flemish carrack which is remarkable for its detail and technical accuracy, in spite of the fact that considerable license must be allowed the artist. Her short foremast and tall mainmast, both surmounted by a top, each carries a single square sail; her stump mizen a lateen. The mizen top mounts a small gun. Her hull, with long forecastle and shorter aftercastle, is very full-lined forward and aft and is greatly strengthened externally. A stump bowsprit at a sharp angle takes the forestay and the bowlines of the foresail, and the anchor is suspended from it. Obviously at that period the Flemings built for strength rather than speed.

THE DEVELOPMENT OF THE SAILING SHIP

In England, Henry V. (1413) built large vessels for his fleet, "great ships, cogs, carracks, ships, barges and ballingers," some of which were of nearly 1,000 tons, but the generality from 420 to 520 tons. In the list of his fleet no galleys seem to be included. Meanwhile in the south the type of vessel called "caravel" was being developed, in which Portuguese and Spaniards dared the Atlantic and made their great discoveries. "Santa Maria," the flagship of Columbus (1492) in his attempt to reach the Indies by the Western route, is generally quoted as typical of this class, but research has cast doubt on her generally accepted dimensions and design and modern discovery is revealing a ship very different from the "replica" built in Spain for exhibition in the United States in 1892. The vessels in which Vasco da Gama first doubled the Cape of Good Hope (1497) were probably of similar type but larger. The ship of John Cabot (1497) in which he discovered Newfoundland must have been much smaller, as he had a crew of only eighteen men.

In England during the Tudor times a great advance in shipbuilding is to be observed; but the French then, as well as at a later period, were providing the best models for naval architecture. These big ships were armed at first with "serpentines," and later with cannon and culverins. The representations of them show several tiers of guns, four or even five masts, and enormous structures by way of forecastles and deck-houses aft. In spite of the general improvement in hull design, however, these ships had many weak points, chief among which, from the fighting point of view, was a beak bow surmounted by a square bulkhead, a feature inherited from the galley. Notwithstanding many expensive lessons, this feature was not finally abandoned in big ships until the early 19th century. As regards merchant vessels, the Genoese and the Venetians during the 15th and 16th centuries carried out great improvements. The "carracks" of the 16th century often reached as much as 1,000 tons burthen. There is a record of a Portuguese carrack captured by the English, of which the dimensions reached 165 ft. in length and 47 ft. in beam. She carried 32 pieces of brass ordnance and between 600 and 700 passengers.

Armada Ships.—The Spanish Armada (1588) was composed of 132 vessels, of which the largest was about 1,300 tons and 30 under 100 tons. Four galleys and four galleasses accompanied the fleet. The opposing fleet consisted of 197 vessels of which only 34 belonged to the royal navy. Of these the largest was the "Triumph" of about 1,000 tons. The "Ark Royal" the flagship of the English admiral, was of 800 tons, carrying 55 guns. Among the armed merchant vessels employed with the fleet was the "Buonaventure," the first English vessel that made a successful voyage to the Cape and India. The result to England of the defeat of the Spaniards was a great increase of mercantile activity. Merchants, instead of hiring Genoese or Venetian carracks, began to prefer building and owning home-built ships, and though the foreign merchant vessels appear to have been on a larger scale, yet, as seagoing craft, the English-built ships certainly held their own. At a rather later date many of their best qualities were marred by mounting a very much heavier armament without the necessary increase in dimensions. We hear also during this period of many improvements in details, such as striking topmasts, the use of chain pumps, the introduction of studding, topgallant, sprit and topsails, also of the weighing of anchors by means of the capstan, and the use of long cables. In the men-of-war the lower tier of guns, which, as in the galleys, had been carried dangerously near the water-line, began to be raised. This improvement, however, does not seem to have been generally adopted in the English ships till after the Restoration. Meanwhile, in the Mediterranean the galley was still in vogue, being only partially superseded by the great galleasses, six of which are recorded to have taken part in the battle of Lepanto (1571), in which the Venetians and their allies employed no less than 208 galleys with single banks and long sweeping oars.

East India Company's Fleet.—During the 17th century the expansion of trade and the increase of mercantile enterprise were incessant. The East India Company organized its fleet of armed vessels up to 600 tons, and fought its way through Portuguese obstruction to the Indian coast. The Dutch were also competing for the trade of the East and the West, and formed similar companies with this object in view. Conflicts owing to commercial rivalry and international jealousies were inevitable. Hence in the British navy the construction of large vessels such as the "Prince Royal" and the "Sovereign of the Seas" (*see* RIGGING), which may be considered as among the earliest types of the modern wooden man-of-war. English oak afforded the best timber for shipbuilding, and skilful naval architects, such as Phineas Pett, succeeded in constructing the kind of seagoing war vessel which eventually gave England the superiority in its struggle with other naval powers in this and the following century. This, however, was by no means easily gained. The Dutch and the French were not slack in the building of merchant vessels and men-of-war.

The French navy especially, under the fostering care of Colbert, was greatly strengthened. During the 18th century it was constantly found that the dimensions of French ships exceeded those of British ships of the same date, and that French vessels were superior in speed. This led from time to time to an increase of the measurements of the various classes of vessels in the British navy. These were now rated according to the number of guns which they were constructed to carry.

Nelson's "Victory."—A 90-gun ship of the line at the beginning of the 18th century averaged 164 ft. in length of gun deck, 47 ft. beam, and about 1,570 tons, while the 40-gun ships now ran to 120 ft. with 34 ft. beam and from 600 to 700 tons. These dimensions, however, were not always maintained, and towards the middle of the century the Admiralty seem to have recognized the consequent inferiority of their ships. The famous and ill-fated "Royal George," launched in 1756, was the result of an effort to improve the line-of-battle ship of the period. She was 178 ft. in length, 52 ft. in beam, was of over 2,000 tons, and carried 100 guns and a crew of 750 men. The "Victory," Nelson's flagship, was built nearly ten years later. Her dimensions were 186 ft., 52 ft., 2,162 tons, and she carried 100 guns. During the same period frigates, which were cruisers carrying their armament on one deck, were built to carry 32 or 36 guns, but in this class also the French cruisers were superior in speed and of larger dimensions. The remainder of the 18th century and the beginning of the 19th witnessed a continuous rivalry in naval architecture, the French and Spanish models being constantly ahead of the British in dimensions and armament. In the American war (1812) the same disparity as regards dimensions became apparent, and the English frigates, and sloops used as cruisers, were generally outclassed, and in some instances captured, by American vessels of their own rate. This as usual led to the construction of larger vessels with greater speed, and though, after the conclusion of the long war, the activity of the royal dockyards slackened, yet the great three-deckers of the last period, before the adoption of steam power, had reached a length of over 200 ft., with more than 55 ft. beam, and over 3,000 tons. (For the further development of warship construction, *see* under the respective classes, *e.g.*, BATTLESHIP, CRUISER, DESTROYER, etc.)

The end of the Napoleonic Wars heralded a very great change in the construction of merchant ships and the conduct of the shipping business, so that the years 1815 and 1816 mark the beginning of a new epoch unusually clearly. The steamship was firmly established, but her uses were very limited and the sailing ship was still predominant.

NINETEENTH CENTURY SAILING SHIPS

The two changes in the design of the sailing ship at the beginning of this period which had most influence on trade and naval architecture were the suppression of the armed merchantman and the encouragement of speed. There was every prospect of a long peace, and its possibilities were much exaggerated in the hopes of the moment, but it was realised that the armed merchantman, which was primarily designed as such, inevitably lost a good deal of her efficiency as a cargo carrier and was a poor substitute for a fighting ship. Merchantmen had been armed from time immemorial, and for protection against both pirates and the enemy it was a very necessary precaution. The ordinary cargo carrier had a very light armament, the number and calibre of her guns being limited by regulation as a precaution against her turning pirate. Her security was very largely maintained by the convoy system, but a number of the finest merchant ships had a very much more powerful battery and carried letters of marque, not because they wished to engage in privateering but because it relieved them of the onerous convoy regulations.

The big East Indiamen were typical of these, carrying between twenty and thirty guns, occasionally on two decks. They were not efficient fighting ships, for their ports were small and their decks were usually too encumbered with merchandise and passenger fittings to permit the guns' crews proper room to work. But the space taken by this battery very seriously interfered with their commercial value.

The East India Company had already lost its monopoly in the Indian trade and it was obvious that its exclusive rights in Chinese waters must soon go as well. The armed Indiamen that it had been building for over two centuries could only exist under a strict monopoly and allied to a military force. When the monopoly went it became necessary to introduce efficiency, greater effort and greater speed at once.

Blackwall Frigates.—These considerations led to the Blackwall frigates which succeeded the company's East Indiamen. They were owned by such firms as Joseph Soames and Green and Money Wigram on the Thames, and T. and W. Smith of Newcastle, and although they were a considerable improvement from the mercantile point of view they inherited many of the features and most of the appearance of the old East Indiamen. Most of the firms which ran them, indeed, founded their fleets on tonnage purchased from the Company, but they were maintained and run on very different lines and quickly showed their influence on trade. They were, however, heavily built, full-lined ships and although they made tolerably good passages it was by their power and seamanship rather than their lines.

It was in the United States that fine lines were favoured for speed, and perhaps the greatest change of all was in their shipyards. Ever since Colonial days American shipbuilders had realised the value of speed and had been far more successful in obtaining it than any of their rivals in other countries. The Baltimore clippers—not to be confused with the later clipper ships—had made a name for themselves in the latter part of the eighteenth century and they represented the improvement which American designers had been able to effect on the lines of the French luggers which visited their ports during the War of Independence and which impressed them greatly by their seaworthiness, speed and other qualities.

These Baltimore clippers were originally used very largely as pilot boats, almost invariably rigged as brigs or schooners, but they became popular in the coasting trade when land communications were difficult and uncertain. The greatest benefit of their speed, however, was found in their ability to carry a reasonable cargo at very high rates to the West Indian Islands and other European Colonies whose trade was supposed to be strictly closed to them, but whose inhabitants were very willing to do business and whose warships found it quite impossible to catch them at sea. In time of war they made ideal letters of marque ships and during the war of 1812–1814 they proved of inestimable value to their country, both as privateers and blockade runners.

They had exceedingly fine lines and were constructed as lightly as possible, so that for general cargo carrying they worked at considerable disadvantage as compared with the full-bodied vessel of greater carrying capacity. But for the cargoes paying high freights or for the carriage of passengers they showed a great superiority.

Atlantic Packet Ships.—The first striking commercial use to which they were put, apart from their contraband trade, was the Western Ocean packet service which opened with the establishment of the Black Ball Line between New York and Liverpool in 1816. To begin with the ships were not extreme in their type, their sail area was moderate and the tonnage of most of them lay between 350 and 500 burthen. They were, however, sufficient to attract attention by the great improvement which they effected on the services that had preceded them, and their adaptation of the Baltimore clipper design was rapidly developed on more extreme lines to cope with the mail, passenger and emigrant business that was increasing by leaps and bounds. At the same time the trade to China and the East was being developed, demanding a slightly different vessel, but the American designers proved themselves quite capable of evolving it. Trade steadily improved and large fortunes were made by enterprising merchants. This Eastern trade employed some of the finest ships in the American Merchant Service just as it had in the British, but their vessels were very much faster.

Clipper Ships.—It is generally agreed, however, that the "Ann McKim" which was built at Baltimore in 1832 for Isaac McKim of that city was the first real clipper ship. She was fully rigged

as a ship, square rigged on all three masts and had a tall tapering sail plan instead of the square plan that was later more greatly favoured for speed. But with her yacht-like lines, low freeboard and raking masts, stem and stern-posts, she completely satisfied the popular conception of a clipper ship, although her registered tonnage was only 493 on dimensions 143 feet by 31 feet beam by 14 feet depth of hold, drawing 11 feet of water forward and 17 aft. She made a number of noteworthy passages on the China trade for which she was designed before being sold into the Pacific, but although she was fast and seaworthy she took on board a lot of water and was very uncomfortable, faults which were found with practically all clipper ships.

This policy of the American builders had an almost immediate influence on ship design in Britain. The virtues of speed were recognised, whereas formerly convoy regulations and the like had made it impossible to hope for a good passage and speed had only been considered to be at all necessary for the carriage of fruit and slaves—"perishable cargoes" as they were somewhat cynically described.

It was in the coasting trade that they first made their influence felt. For many years the various coasting services, particularly on the East coast of Great Britain, had been maintained by cutter-rigged sailing craft, the smacks for the longer distances and the hoys for the shorter routes. These smacks varied in size up to 75 feet in length by 23 in beam, their burthen going up to 160 tons and more. The hoys were generally smaller but neither craft offered any great comfort to its passengers. The coasting trade therefore gave the steamers a great opportunity, and they were not slow to take it. Numerous coasting services were opened in the 'twenties and the Aberdeen shipowners replied to this new competition by producing an adaptation of the American clipper, the first vessels of the type being almost invariably schooner rigged and employed on the coasting service. Later they became more ambitious and rivalled the Americans on the Western Ocean and eventually on the Eastern trades.

The American owners were ill-disposed to give the British this place in the rapidly growing emigrant trade on the Atlantic and improved both the size and design of their vessels in order to meet the competition. Their ships became more and more extreme in their fine clipper lines, and by carrying sail until the last moment they made some magnificent passages which were fully advertised and appreciated at the time. In those days the emigrant had to provide his own food and very few of them had sufficient knowledge to bring on board enough for a prolonged voyage, so that fast passages were the best possible advertisement and the fastest ships skimmed the cream of the trade.

Auxiliary Sailing Ships.—While the steamship was making rapid progress in Europe the Americans were for the most part content to develop it on distinctive lines for their own local and coasting purposes. As far as their ocean trade was concerned they had the reputation of building and possessing the finest clipper ships in the world and they were satisfied with that. They tried auxiliary machinery on the North Atlantic in what was essentially a sailing ship in the case of the "Massachusetts" of 1845, a 751-ton ship with an Ericsson screw propeller. She was not a success and was soon afterwards sold to the United States Navy. The auxiliary principle had already been tried in Britain in the case of Green's Blackwall frigates "Vernon," "Owen Glendower" and "Earl of Hardwicke," with lifting paddles. Their engines of 32 horse-power were intended to give a speed of five knots in a calm but they were very seldom satisfactory. In the 'fifties there had been a craze for them in the Australian trade and many prominent shipowners were ruined by them.

In 1849 the British Navigation laws were repealed and the American clipper ships were able to bring cargoes of China tea to British ports. Their appearance created a sensation, and one or two British builders, both at Aberdeen and on the Clyde, were tempted to copy them and produce fast sailing clipper ships of large tonnage. Until 1854, however, they were handicapped by the old rules of tonnage measurement which only took length and beam into consideration and left depth untaxed. The result was a short, deep ship not approaching the Americans in speed.

The first American clipper to load tea for the British market was the "Oriental," one of the extreme American ships of her day which brought a cargo of tea to London at £6 per forty cubic feet, while the best that the British ships could obtain was £3.10 per 50 cubic feet. She arrived in the West India Docks early in December 1850, 97 days out from Hong Kong, and created a sensation. The immediate result was that the British clippers "Stornoway" and "Chrysolite" were ordered at Aberdeen in spite of the tonnage laws, the first of their type. Although they were remarkably fast vessels in normal weather their lack of beam lost them speed in strong winds, but this fault was rectified in later designs.

In spite of their opportunities in this market, it was not long before the Americans deserted it, for the discovery of gold in California caused an unprecedented rush from the Eastern States and, as the passage by way of Cape Horn was technically a coasting run, it was reserved to American ships, their clipper owners having nothing to fear from cheaply-manned foreign competition. There was little enough cargo to be carried, but any number of gold seekers, so that in the early 'fifties a number of American clippers were built, growing more and more extreme in their fine lines, and made large profits.

The British clipper shipowners were developing the China and the Australian trade in the same way, although their ships never approached those of the Americans in their fineness. Freight and passage rates were both high and it was possible to earn an excellent dividend on a ship with very limited cargo capacity. Many British owners went to American yards for their tonnage, particularly to that owned by Donald McKay of Boston, but at the same time there were magnificent ships turned out by British establishments. As a general rule the hard wood British ship lasted longer than her American rival which was built of soft wood, but the first cost was considerably higher—some 25 per cent—and in any circumstances these clippers were driven so hard that few of them lasted many years on the first class services.

Large Sailing Ships.—It was the promise of the Australian trade that caused Donald McKay to build his masterpiece, the "Great Republic" of 1853. She was the biggest ship in the world and was one of the first vessels to be rigged as a four-masted barque. Failing to obtain backing among shipowners, McKay determined to run her himself between the United States and Australia. Her registered tonnage was 4,555 and in order to keep the crew within reasonable limits she was fitted with patent double topsails and a 15 horse-power steam engine on deck for handling the yards and working the pumps. Her hull was of oak and pine, iron strengthened, and she attracted great attention. Unfortunately she caught fire and had to be scuttled while loading for her maiden voyage, so never went to sea as McKay had originally designed her. He was forced to sell her and her purchaser cut down her rig considerably but even then she was too big to be run to satisfactory profit on commercial service. She did good work trooping in the Crimean and American Civil Wars before she finally foundered, as the "Denmark" of Liverpool, in the North Atlantic in 1872.

From the early 'sixties American shipping, which until then had been predominant, suffered an eclipse and this is frequently but erroneously ascribed to the effect of the American Civil War. It is true that a handful of Confederate cruisers captured a number of ships owned in the North, and that many American shipowners transferred their big sailing ships to foreign flags in consequence. The real explanation is that American enterprise was turning towards the West, where there were golden opportunities. The conservative element would not abandon the wooden sailing ship with which they had made their reputation, while Europe had seen the advantages of steam and iron so that the handicap was changed. In the late 'sixties composite construction, that is to say wooden planking on an iron framework, became popular and such famous ships as the "Cutty Sark" were built after this fashion.

For many years the sailing ships had one great advantage over the steamers in that the huge coal consumption of the latter's machinery made it very difficult to run them at a profit on routes

where coal was dear or where the bunkering stations were far apart. As steamers became more economical this handicap was gradually removed, and the opening of the Suez Canal in 1869 forced sailing ship owners to cut down their running expenses and increase their carrying capacity if they were to compete with the steamer. Clipper freights were no longer to be obtained, and without them the fine-lined clippers could not be run at a profit. Not only would they not stow sufficient cargo, but they made it necessary to maintain a large crew. The ship rig, that is to say the sailing vessel with yards on all her masts, had been introduced in the early days of convoys and fleet tactics in order that speed might be regulated by backing the squaresails on the mizzen. It was maintained by most of the fast ships after the convoy days had ended more or less as a matter of tradition, for under all plain sail it made very little difference to the actual speed of the ship, while the barque rig, in which the aftermost mast was fore and aft rigged and the others square, meant a very considerable economy in men. Thus, although the full-rigged ship did not disappear rapidly, many of the new ships laid down were barque rigged and many existing ships were converted, while owners no longer gave orders for extreme clippers but insisted on a fair carrying capacity. Some of these vessels with fuller lines made remarkably good passages, and they were invariably more comfortable than the clippers.

Iron sailing ships also became almost universal on account of the saving on their weight in their hull, and finally the steel ship came into existence for the same reason. In the early 'nineties there was a considerable revival in the construction of sailing ships in Great Britain, invariably designed to carry the maximum load at reasonable speed with the smallest possible crew. The British yards turned out a considerable number of ships at this time but still more, proportionately, were built for French owners who had the greatest assistance in running their ships by the navigation bounties offered by the Government, bounties that were so considerable that it paid a shipowner to take a sailing vessel round the world without a ton of cargo on board. The Germans also built a number of large sailing vessels, some with auxiliary machinery, principally for their trade with the nitrate ports on the West coast of South America.

The American sailing ship owners lost the greater part of their enthusiasm for square rigged ships when the trans-Continental Railways finished the Californian trade, although a few were built even into the present century. The "Atlas" of 1902 was their last big iron ship, but some owners favoured the wooden construction with which they had made their name right into the 'nineties, the "Aryan" of 1893 being the last. Until a very much later date, however, American owners took an interest in the multiple masted schooners which they made peculiarly their own. Although they were sent on ocean voyages these schooners were particularly adapted for the American coastal trade, where they carried large cargoes with very small crews; the wooden 6-masted "Wyoming" (3,730 tons built in 1909) and the steel 7-masted "Thomas W. Lawson" (5,218 tons built in 1902) were extreme specimens of this type.

Modern Sailing Ships.—The Germans have continued to build a number of big sailing vessels, both with and without auxiliary power, until the present day. One reason for this is that the German regulations insist on sail training before an officer can receive any of his certificates. The "Padua" built in 1926 of 3,064 tons gross is a fine example of these ships. More economical in men are the auxiliary schooners, with square topsails on alternate masts, built by the Vinnen Company after the war, of which the "Werner Vinnen" of 1,859 tons, built 1922, may be taken as typical. The Danish East Asiatic Company had a big auxiliary training ship rigged as a five-masted barque built at Leith in 1921, the "Köbenhavn," of 3,901 tons.

Apart from these, however, and a few sail training ships built for naval purposes, the large sailing vessels now at sea are principally old ships which have passed under the various Scandinavian and other flags to be run as cheaply as possible at the end of their days. The last surviving British square rigged ship at sea (1929) is the "Garthpool," a four-masted barque of 2,842 tons built as the "Juteopolis" in 1891.

During the World War a large number of wooden auxiliary schooners were built, as rapidly as possible, to replace losses caused by the German submarine blockade, but the great majority of these have been broken up since the Armistice.

INTRODUCTION OF STEAM AND IRON

A revolution in the history of the ship may be said to have occurred with the changes from sails to steam engines for propulsion and from wood to iron for construction. These proceeded together, but at first very slowly. Conservative tendencies in many quarters, notably at the British Admiralty, strongly resisted the introduction of the steam ship, while the marine engine itself was undoubtedly somewhat imperfect and extravagant in fuel in its early stages. As already stated, there was still much ignorance of the principle of flotation by displacement, and it was urged by the unenlightened that iron would not float and was therefore unsuitable for ship construction. Even amongst those who realised the fallacy of this argument it was asserted that an iron ship would be far more easily damaged in the event of her touching the ground than a wooden one, while there existed the very real difficulties of preserving the bottom from the action of the sea and fouling by weeds and barnacles, and of compensating the compass for the errors produced by local attraction. With regard to the strength of the ship, experience showed that iron construction was better able to withstand rough usage than wood, and examples were not lacking of iron and wooden ships being stranded together by the same gale and under similar circumstances and the iron ship getting off little the worse, while the wooden ship became a total wreck. A remarkable instance of the endurance of iron ships was that of the "Great Britain," which, in 1846, ran ashore in Dundrum Bay in Ireland and settled on two detached rocks; she remained aground for eleven months, was subsequently got off, and afterwards did good service. In due course a suitable composition was discovered for painting the underwater surface of iron ships, while trials carried out in the "Rainbow" at Deptford and the "Ironside" at Liverpool went far towards providing the solution for correcting the compass.

One of the earliest iron craft on record was a boat apparently intended for passenger service, built on the banks of the river Foss in Yorkshire in 1777. In 1787 a canal lighter was constructed with a shell of iron plates, and for many years iron and wood were used in conjunction for the construction of what were known as composite ships.

For warships iron was at first objected to because it was thought that the enemy's shot would cause more serious damage to them than it would to a wooden ship, but this again was proved to be a fallacy.

PADDLE WHEEL STEAMERS

In 1786, James Rumsey drove a boat on the Potomac four miles an hour by means of a power pump. About the same time John Fitch produced his oar-driven steamboats. A more practicable device was to be the paddle wheel. The "Charlotte Dundas," constructed by Symington in Scotland in 1801–2, was one of the earliest of these vessels. She proved her utility for towing work on the Forth and Clyde Canal. Fulton, having witnessed the success of this craft, in 1807 constructed the "Clermont" on the Hudson River in America. The engines for the vessel were made by Boulton and Watt in England. She proved very popular as a passenger boat between New York and Albany. The first steamer to make a regular sea voyage was the "Phoenix" which, in 1809, steamed from Hoboken in New Jersey to Philadelphia. In 1812 Bell produced his steamer "Comet," which carried passengers between Glasgow, Greenock and Helensburg. She was 42 feet long, 11 feet broad, 5½ feet deep, and was driven by a one-cylinder engine. The success of these early steamers soon produced others, and in 1814 there were five steamboats on the Thames, while the "Marjorie," built on the Clyde, was brought through the Forth and Clyde Canal and then down the East Coast to this river.

In the United States the monopoly that had been granted to

Robert Fulton to maintain steamships on the waters about New York tended to check progress for a time, although it is doubtful whether he would have been able to develop his steamers so rapidly had it not been granted. As other inventors and engineers found themselves able to construct steamers Fulton's monopoly forced them further afield, and resulted in the development of the steamship business on other American waterways and then along the Eastern coast of the United States.

Similarly in Great Britain the steamship was first only used as a passenger carrier and tug along rivers and canals, but gradually increased competition forced the steamer to seek other spheres and in doing so she found herself able to perform short coasting voyages. She then became a passenger carrier along the coast to the various holiday resorts, her novelty being her principal attraction. It was not long before it was realised by the owners that the steamship was capable of very much more than this and vessels were built to cross the North Sea, the Straits of Dover and the Irish Sea. They were all modelled on the sailing ships that they replaced and all carried auxiliary sail either on masts or on their funnel, while the low-pressure machinery was very wasteful and incapable of giving any considerable speed. The various methods of propulsion which had been experimented with in the eighteenth and earliest years of the nineteenth centuries, including a rudimentary screw propeller and jet propulsion, gave way to the side paddle wheel which remained in favour for many years.

Atlantic Crossing.—It was not long before steamship owners aspired to cross the Atlantic by steam. The sailing packet "Savannah," which had been designed to run on the service between New York and Havre, was given auxiliary steam machinery and crossed the Atlantic from Savannah in May and June 1818. She only used her engines for 80 hours of the voyage, but arrived in Cork with her coal consumed. Afterwards she visited the Baltic, where she aroused great interest. Although this is generally recorded as the first steam Atlantic crossing, the small use to which she put her machinery really robs her of that honour.

The ship to which it really belongs is very generally omitted in the histories, the Dutch steamer "Curaçao." She was built at Dover in 1826 for the cross Channel service and was then renamed "Calpé," a wooden paddler of 438 tons register whose paddles were driven by independent engines. As soon as she was completed she was purchased by the Dutch Government as a man-of-war but was employed on the mail service to their West Indian Colonies. She left Rotterdam on her first passage to the West Indies in April 1827 and took a month to do the voyage, after which she made the regular sailing each year, until she was required as a warship during the troubles in Belgium in 1830, after which she never returned to the mail service.

The next steamer to perform the feat was the "Royal William," whose performance was particularly remarkable on account of the fact that she was built in Quebec with the idea of running from that port to Halifax. Samuel Cunard, who afterwards founded the great Atlantic company, was one of her owners. Trade depression and an epidemic of cholera spoiled her chances on the trade for which she was designed and she did no better as a tug. Her owners, being forced to consider her sale and thinking that they would get a better price for her in Europe than in Canada, sent her across the Atlantic in 1833. She took 25 days to do the passage and burned 330 tons of coal. Afterwards she was sold for £10,000 and later served in the Portuguese Navy as a transport and in the Spanish Navy as a warship until she was finally condemned in 1847.

Regular Atlantic Passages.—These early steamship passages across the Atlantic were more or less haphazard, but it soon became the object of the owners to provide a regular service. Pending the construction of suitable tonnage the 703-ton steamer "Sirius," which had been built for the Irish Sea service, was chartered in 1838 by the British & American Steam Navigation Company. She was considered a big steamship in her day and was one of the first steamers to be fitted with a condenser instead of using salt water in her boilers, one of the milestones of steam engineering at sea. She sailed from London to New York by way of Cork with 100 passengers and although she was grossly overloaded to modern ideas she made the passage in safety. Within a few hours of her arrival in New York a very much bigger and finer steamer, the "Great Western," which had been constructed with the idea of continuing the Great Western Railway across the Atlantic, arrived after a crossing of 15 days from Bristol. She had a tonnage of 1,440 and was regarded as the finest steamship of her day.

After this several other Atlantic liners were built but all the services were irregular and maintained by a heterogeneous collection of ships, suitable and unsuitable. It was when Samuel Cunard founded the line which still bears his name in the year 1840 that a new policy in shipping produced a revolution in shipbuilding—the construction of sister ships. He started operations with four transatlantic ships and one small feeding steamer in Canadian waters.

The sister ships "Britannia," "Acadia," "Columbia" and "Caledonia" were wooden steamers built on the Clyde, their tonnage according to the rule then in use being about 1,150 on dimensions 207 feet by 34 ft. 2 in. by 22 ft. 2 in. depth of hold and their two-cylinder side-lever paddle engines of 740 I.H.P. being sufficient for an average speed of nine knots in favourable circumstances. The coal supply of these ships was the chief anxiety of their designers, and their passenger accommodation was not equal to the sailing packets which they rivalled, but the regularity of their passages compensated for the fact that they were frequently beaten by the sailing ships in a fair wind. They were barque rigged and had a considerable area of canvas which was set whenever circumstances were favourable.

Long Distance Steamers.—In the meantime, although the North Atlantic crossing had attracted popular attention to the exclusion of most other services, great progress was being made in the long distance routes. When the General Steam Navigation Company, the oldest British purely steamship company, was founded in 1824 its promoters had the intention of running steamship services all over the world as material improved, and had every confidence that this would come about.

In 1825 the steamship "Enterprise" had proved that it was possible for a steamer to reach India, although at the same time she proved that it was not a commercial proposition. It had been suggested in 1822 to establish a company for the purpose of maintaining a steam service to India and a naval officer was sent out to arouse popular enthusiasm. Within two years 80,000 rupees had been raised in Bengal by public subscription, to which the Government of India added 20,000 rupees and announced that the whole sum would be given as a prize to the first steamer that could contrive two round voyages between Great Britain and India before 1826, the stipulated time for each passage being 70 days.

This prize caused a syndicate to purchase the paddle steamer "Enterprise" of 479 tons when under construction on the Thames and to fit her out with a fore-and-aft rig to compete for the prize. Her dimensions were 122 feet by 27 and she had an engine of 120 nominal horse power which was designed for nine knots speed but which could be relied upon for six or seven only. She sailed from Falmouth on August 19, 1825 and reached Calcutta 113 days out, including ten days spent coaling at St. Thomas and the Cape of Good Hope. The Government of India awarded her half the promised prize and then purchased her as a warship.

The long route by way of the Cape having proved unprofitable for steamers, the East Indian Government surveyed the Suez route and had steamships built to maintain a more or less regular service from Bombay to Suez, whence the mails and passengers were conveyed across the Isthmus to the Mediterranean. In the early days of the service the European end was maintained by sailing vessels.

The improvement and finally the real practicability of the overland route was brought about by the Peninsular and Oriental Line, which started in 1834 to maintain a mail service between Great Britain and the Spanish and Portuguese ports in competition with the sailing mail packets maintained by the Government. It was then the Peninsular Line, but in 1839 the service was ex-

MODERN PASSENGER AND CARGO SHIPS

1. The four-funnel passenger liner "Mauretania," the fastest ship crossing the Atlantic in 1928. 2. "Duchess of Bedford," 20,000 ton cabin-class ship for the Canadian trade, the latest of her type. 3. A 14,500 ton intermediate liner, "Highland Monarch," used for the South American trade. 4. "Asturias," first-class 22,000 ton motor liner for South American trade. Shape of funnel obviates possibility of exhaust echo's confusing officer on watch. 5. "Minnekahda," a post-war liner devoted to the third-class tourist trade and the carrying of cargo. 6. "Beaverburn," modern transatlantic cargo liner, a type credited with remarkable speed and economy. 7. "Dramatist," a typical steam cargo liner. 8. "Suffolk," one of a fleet of frozen-meat carrying ships that serve the Australian trade. 9. "Selandia," a small 4,950 ton craft built in 1912. This ship was the first ocean going motor ship. 10. "Clan Macdonald," an up-to-date motor cargo liner. 11. "Naronic," passenger carrier of the type in common use on the Great Lakes. 12. "Livingstone," a modern Canadian grain carrier for the Great Lakes trade, designed to pass through Welland Canal and unload alongside ocean-going steamers

DIFFERENT TYPES OF STEAMSHIPS

1. "John Bowes," the first steam collier, as reconstructed and now running
2. "Felspar," modern British coasting collier
3. "Sheafarrow," modern ocean collier built on the arch principle
4. "Southern Wave," late type of whale catcher as used in the Antarctic
5. "Hibernia," typical of the standard type of turbine packet in British waters for many years
6. "Worthing," an up-to-date British packet with closed-in deck. The single funnel interferes as little as possible with passenger accommodations
7. "Leda," a medium-speed Norwegian packet, typical of the vessels crossing the North Sea
8. "Waialeale." This steamer shows the latest trend in American packet design
9. "Minto," a modern icebreaker
10. "Rescue," a tug of the type used for salvage work
11. "Dominia," modern, large-type cable ship
12. "El Oso," typical tank steamer of the post-war period

tended to Alexandria to connect with the East India Company's steamers and the company became the Peninsular and Oriental Line. It was not until 1854 that the East India Company abandoned its end of the service, although its irregularities and the poor steamships employed on it were the cause of constant complaint.

Steamships of a type practically identical with those of the Cunard Line, but of rather greater tonnage varying from 1,700 to 1,900, were built in 1839 for the West Indian mail service for which the Royal Mail Steam Packet Company had obtained a Royal Charter. At that period the British West Indian colonies were of much greater importance than in more modern times, and the service was heavily subsidised in order to overcome the very great difficulties of coal supply on the route. This service was afterwards extended to the Brazilian coast and the River Plate, causing a steady increase in the size of the ships, although they were for long built on the same principle.

This was very largely due to the fact that the Admiralty had a considerable influence on their design in return for the mail subsidy, and insisted on the ships approximating the wooden paddle frigates of their day whose vulnerability, although frequently pointed out by experts, had not yet been proved in action. The hulls therefore all followed approximately the same lines, the owners only being allowed a reasonably free hand in the matter of machinery, in which the economy which was so essential was steadily improving.

The Screw Propeller.—Private shipowners who were untrammelled by the conditions of their subsidy were anxious to improve on the paddle wheel and in 1836 both Francis Pettit Smith, an Englishman, and Captain John Ericsson, a Swede, patented practical screw propellers although the principle was not new. The year 1839 saw a ship built to each of these principles, the "Archimedes" to Smith's patent and the "Robert F. Stockton" to Ericsson's. They were neither of them large vessels, but they both proved the superior economy and power of the screw and led to more important ships being built.

The most important of these steamers was the "Great Britain," which was laid down in dry dock at Bristol in 1839 and floated out in 1844. She was not only noteworthy on account of her dimensions, which were 322 feet by 51 by 32 feet 6 inches depth of hold, which gave her a tonnage of 3,448 according to the old burthen measurement, but also because she was constructed of iron in spite of the great prejudice of the Navy against that material. She was designed by I. K. Brunel, whose intention was originally to make her a paddle steamer. But he was so greatly impressed by the performances of the "Archimedes" on a cruise round the British coast that he altered it and fitted screw machinery, reinforced by a big sail area on six masts.

Her machinery consisted of a simple engine with four cylinders each 88 inches in diameter, with a stroke of 72 and with indicated horse power of 2,000 at five lb. per square inch pressure, a speed of twelve knots being obtained on trial. Her stranding on the Irish coast in 1846, when she had to withstand the gales of a whole winter in an exposed position, finally convinced shipowners that iron construction was both strong and practical.

In 1847 the Americans brought out their first transatlantic steamers to their own ideas, the "Hermann" and "Washington," which were run by the Ocean Line between New York and Bremen by way of Southampton in return for a heavy subsidy. They were ships of 1,850 tons each with paddle engines of 1,400 tons, giving them a speed of eleven knots, their hulls being on the lines of the less extreme Atlantic sailing packets. They maintained their service with fair success until the reversal of the United States subsidy policy in 1857, when they were sent to end their days in the Pacific. In 1850 a second American transatlantic service between New York and Havre was started with the "Humboldt" and "Franklin."

American Atlantic Design.—The straight stem of these two ships made them differ greatly in appearance from their British rivals and was purely an American conception which was introduced by Mr. E. K. Collins when he started the Collins Line under the American flag in 1849. The first fleet consisted of the wooden paddle steamers "Atlantic," "Arctic," "Baltic" and "Pacific," practically sister ships of 2,860 tons, with beam engines of 2,000 I.H.P. They were a great improvement on the existing material and although they were so well built and extravagantly fitted that it was necessary to obtain an additional subsidy they were the most noteworthy ships on the Atlantic in their day. In 1856 they were joined by the "Adriatic," of 5,888 tons gross with engines of 4,000 I.H.P. designed for a speed of 13½ knots, which marked the high water mark of American paddle steamer construction on the Atlantic. When the subsidy on which the company relied was suddenly withdrawn after two disasters the service collapsed and although Commodore Vanderbilt constructed somewhat similar ships to maintain the Stars and Stripes on the Atlantic they were soon withdrawn and for over thirty years American steamship development was practically confined to the rivers and coasts of the country, and the Pacific trade.

While these big paddle steamers were being built the screw propeller was being introduced into European Atlantic companies, beginning seriously with the foundation of the Inman Line in 1850. This company, which was intended to improve the emigrant service, began with iron screw steamers—the first of under 2,000 tons—barque rigged and still maintaining a full spread of canvas. Its example was soon followed. The North German Lloyd and Hamburg American Companies in Germany, and the Compagnie Générale Transatlantique in France, saw the opportunities of the great Continental fields of emigration with up-to-date steam tonnage and were soon encroaching on the third class traffic which was the last stronghold of the sailing packet.

The Cunard Line was endeavouring to carry on in its traditional way, in spite of the fact that by then the naval conditions were considerably relaxed, but it was gradually being forced into line. For its mail ships it remained faithful to the paddle until the early 'sixties, the "Scotia" of 3,871 tons which was launched in 1862 being the last and finest of the type. It had, however, changed from wood to iron with the "Persia" of 1856 and had purchased the screw steamer "British Queen" of 773 tons in 1850. On the experience gained with her the company had the "Alps" and "Andes" built for the West Indian service in 1851 and were so satisfied with them that the screw steamer "China" of 2,529 tons was practically contemporary with the "Scotia" and in spite of her smaller size showed her advantages in competitive service trials.

The "Himalaya."—In 1853 the Peninsular and Oriental Line, although they were not destined to abandon the paddle for some years afterwards, built the iron screw steamer "Himalaya" which was the biggest vessel of her type in the world, having a gross tonnage of 3,438 on dimensions 340 by 46·2 by 34·9 feet depth of hold. Her trunk engines gave her a speed of 13·9 knots on trial, and yet were sufficiently economical to permit her to stow enough fuel to undertake long voyages under steam which showed a profit. After one or two voyages on her owners' service she was taken up as a transport for the Crimean War and so impressed the Admiralty that they bought her and employed her as a naval trooper until the 'nineties. She was then converted into a coal hulk and still (1928) performs that duty at Portland.

"Great Eastern."—The "Great Eastern" is perhaps the most discussed steamship that has ever been built, and the most historic failure. She was originally conceived by Mr. I. K. Brunel on the success of the "Great Britain," and in 1851 a company was floated for the purpose of building her and trading to the East. At that period steam navigation to the East and Australia was greatly handicapped by the lack of coaling facilities, and the "Great Eastern" was specially designed to ply between England and either Calcutta or Colombo, where smaller steamers and sailing vessels could pick up her cargo and passengers and distribute them to various destinations. Her dimensions of 692 feet on the upper deck by 82·5 feet beam and 30 feet draught gave her a gross tonnage of 18,914, and it became necessary to take particular precautions that her hull should have the requisite strength. She was therefore not only given a double bottom, but a tubular upper deck and was one of the strongest ships ever

built. The hull and the paddle engines were built by Messrs. Scott Russell and Co. on the Thames, while James Watt & Co. of Birmingham built the screw engines, for Brunel had decided to provide alternate methods of propulsion, the greatest fault in the original design. Mr. Scott Russell of the building firm designed the details of her hull and gave her the wave line principle in which he believed. The paddle engines indicated 3,411 horse power, while the screw engines which drove a four-bladed propeller indicated 4,886. Altogether 6,500 square yards of canvas were set on her six masts and she was fitted with ample bunker accommodation for a long voyage, in addition to large holds and passenger accommodation.

Fearing for the narrowness of the river, Brunel insisted that she should be launched broadside on and was so anxious to avoid the huge mass taking charge that he checked her too soon on the ways and she stuck fast for three months. This delay, and the subsequent work of launching her, drove the original company into liquidation and she was purchased for use on the North Atlantic, a service for which she was not designed and was most unsuitable. The result was that she was a most expensive failure except for the excellent work that she did in laying the Atlantic cable.

By this time the screw steamer was invading most of the trades of the world, including the coastal. The Americans were building up a fine coasting fleet to their own requirements, differing very materially from European ideas of design. Most of the European nations were following suit, while steam colliers were even invading the coal trade between the North East coast of England and the Thames, which was regarded as the stronghold of the sailing ship. The first was the 273-ton "Q.E.D." which was really an auxiliary, schooner rigged, with the smoke from her low-powered screw machinery carried up through her mizzen mast. This vessel made her appearance in 1844. Eight years later, however, the first real iron steam collier was put into service, the "John Bowes." This steamer had dimensions 151 ft. 9 in. by 26 ft. 3 in. and was one of the first ships to be fitted with tanks for water ballast. Rebuilt out of all recognition, she is still busy on the Spanish coasting trade as the "Valentin Fierro."

A far more important result of her success was that it caused the introduction of the steam tramp, a cargo vessel which was open to charter on any trade instead of running to a definite schedule. Before that time all steamers were built for definite services and chartering for bulk cargoes was unusual, this business being left almost entirely to the sailing ship.

The Expansion Engine.—Increased economy was still the aim of the engineer, and this led to the introduction of the expansion engine, in which the steam was used in a second cylinder at a lower pressure after it had done its work in the first. It was an invention of James P. Allaire, the American engineer, in the year 1824, but at that time it failed owing to the low pressure used. As steam pressure increased John Elder, the head of what is now the Fairfield Yard on the Clyde, brought out his compound engine which employed the steam in two stages, and which did much to overcome the disadvantages of the steamship on long routes on which coaling stations were rare.

The first vessel to be so fitted was the "Brandon" of 1854, a screw steamer designed for the trade between London and Limerick, and fitted with a vertical engine having the cranks diametrically opposite to one another. Her coal consumption on trial was returned as 3¼ lb. per I.H.P. per hour, as compared with the 4 to 4½ lb. which was the utmost economy to which the simple engine could aspire. Although built for a short distance service she was employed as a transport in the Crimean War and her success caused the compound engine to be very generally adopted, while the steam pressure steadily increased.

As this pressure increased it became possible to add a third stage to the engine and triple expansion machinery came into being. In France this system was sponsored by M. Benjamin Normand of the famous firm of Havre shipbuilders, who took out a patent in 1871 and installed his first set two years later. In England a patent was taken out by Dr. A. C. Kirk, a colleague of John Elder, who tried a triple expansion engine and machinery first in 1874 in the 2,083 ton steamer "Propontis."

Water Tube Boilers.—The original installation of the "Propontis" was fed by water tube boilers, in which the water passed in tubes through the flame instead of the flame passing in tubes through the water as in ordinary mercantile practice. These boilers, which are now generally adopted in all navies and in many merchant ships, had already been introduced in France but had given much trouble. Those installed in the "Propontis" were no more satisfactory than those of French men-of-war which had been so fitted in the 'forties and she is generally described as a failure, but when new boilers were installed with reduced pressure she continued to work satisfactorily for many years.

In 1881 the "Aberdeen" of 3,616 tons, designed to run on the Australian trade in which economy was more obviously necessary than in any other, was fitted with Kirk's triple expansion engines. On trial she reduced her coal consumption to 1·28 lb. per I.H.P. per hour and was a most satisfactory vessel on service, although this abnormally small consumption was naturally increased under working conditions. Her success caused a very large number of steamers of all kinds, which had originally carried compound engines, to be tripled by the addition of a third cylinder during the 'eighties and 'nineties.

At the end of the nineteenth Century steam expansion was taken one stage further and a few quadruple expansion engines were built for marine use, but their employment was strictly limited.

Twin Screws.—In 1862 the first full-powered twin screw steamer, apart from certain experiments in the very earliest days of steam, was built on the Thames. She was the 400-ton "Flora" and although her builders, Messrs. Dudgeon, made a speciality of twin screw steamers and built the far larger "Ruahine" in 1865 for the Panama, New Zealand and Australian Royal Mail Company, the idea did not attract the liner companies until the "Notting Hill" of 1881 proved the advantages of the system on the North Atlantic. Even so the single screw was not abandoned at once and as recently as 1896 first class liners were built with one shaft only, in spite of the uneasiness caused by several serious accidents.

As the power of ships increased the danger of broken shafts was multiplied, and triple and quadruple screw ships came into being at a later date, although serious disadvantages were involved.

Turbine Ships.—The experimental "Turbinia," built at Wallsend on the Tyne in 1894 and given turbine engines invented by the Hon. Charles Parsons, revived one of the earliest principles of employing power and proved that it was capable of being used at sea. Her dimensions were 100 feet by 9 feet beam by 3 feet draught, her displacement being 44½ tons. The original machinery installation consisted of three steam turbines, totalling 2,000 shaft horse power and each driving a shaft carrying three screws in order to overcome the disadvantages of high propeller speed. During the Diamond Jubilee Naval Review of 1897 she was taken down to Cowes secretly and suddenly dashed out among the assembled ships at what was then the astounding speed of 34½ knots. Naturally she caused a great sensation and the Admiralty built two turbine-engined destroyers which unluckily came to grief, the one by stranding and the other owing to her light construction. There was a tendency to blame the machinery, which had nothing to do with either mishap, and it was some time before Mr. Parsons could persuade commercial shipowners to take an interest in his invention.

The "King Edward" of 1901 was the first merchant steamer to be given turbine machinery, a Clyde passenger steamer which is still running after material alterations. She was followed by the cross Channel packet "The Queen" of 1903 which proved herself greatly superior in speed and far more economical than the paddlers which had preceded her on the service between Dover and Calais. The next important ships to be built on this system were the Allan Liners "Virginian" and "Victorian" of 1904, ships of about 10,750 tons gross each with a trial speed of nearly 20 knots. With all these ships there was a certain amount of trouble in the early days, but the turbine made steady

progress and proved its reliability in the Cunard Liner "Carmania" (19,566 tons) of 1905, which is still running with her original machinery and whose success resulted in the turbine being adopted by the Cunard steamers "Mauretania" and "Lusitania," which were the biggest and fastest liners in the world when they were built in 1907. In 1928 the "Mauretania" still held the Atlantic record which she lowered in 1910.

The 22-foot steam launch "Charmian" was the first vessel in which intermediate gearing between the turbine and the propeller was tried, the experiments taking place on the Tyne as early as 1897 and being practically contemporary with similiar experiments carried out on the Continent. It had long been realised that the efficient speed of the turbine was far too great for the propeller, which was the reason why multiple screws were fitted to the shafts of the early passenger steamers. In 1909 these experiments had produced sufficient promise to warrant the cargo steamer "Vespasian" having her old triple expansion engines taken out and turbine machinery with single reduction mechanical gearing substituted. The great increase in speed and economy which was immediately obtained drew attention to the possibilities of the turbine for cargo as well as fast passenger vessels, and from this it became evident that the gearing, whether it was single or double reduction, was of the greatest advantage even at the maximum speed so that the direct coupled turbine is now regarded as obsolete at sea. Other experiments have been made with hydraulic gearing of the Foettinger and other principles to obtain the same result, while many regard the electric drive, which is described below, as being little more than another form of gearing.

In the "Otaki," a triple screw cargo steamer built for the New Zealand Shipping Company in 1908, Messrs. Denny of Dumbarton the shipbuilders, co-operating with the Parsons Steam Turbine Company, made a successful effort to combine the advantages of the turbine and reciprocating engines. This ship was given a triple expansion engine on each of the two wing shafts, the steam exhausting from them into a low pressure turbine on the centre one. In competitive trials with two ships of similar hull design but more normal engines she averaged a knot greater speed with eleven per cent less coal consumption, although for a cargo vessel the interruption of the after holds by the three shafts was recognised as a serious disadvantage.

For passenger steamers the system promised even greater economy and was later fitted into several large liners, notably the White Star steamer "Olympic" (built 1911, 46,439 tons gross) with conspicuous success.

After the war the same idea was put forward by German engineers in the Bauer-Wach system, in which the disadvantages of the three shafts are avoided by placing the turbine directly abaft the reciprocating engines on the same shaft, with a clutch which disconnects it automatically when it is desired to manoeuvre. An economy of 15 per cent and more has been proved possible with this system, which is particularly well suited for cargo ships and which is being installed in a number of existing vessels just as compound engines were converted into triple expansion in the 'eighties and 'nineties.

HULL IMPROVEMENTS—INTRODUCTION OF STEEL

Improvements in the hulls of steamers were introduced steadily while machinery was being improved, principally with the idea of increasing the strength and carrying capacity and reducing the weight of hull necessary. Iron had shown itself to be superior to wood in these respects, and the next step forward was the introduction of steel for shipbuilding. In 1876 a small steel paddler was built for river service in Burma and in the following year the British Navy built two fast dispatch vessels, the "Iris" and "Mercury." The first sizeable merchant ship to be so built was the "Rotomahana," a ship of 1,777 tons built by Denny on the Clyde for the Union Steamship Company of New Zealand in 1879. Within a few months she was followed by a very much bigger and more important ship, the Allan Liner "Buenos Ayrean" of 4,005 tons for the Canadian mail service. Although it was recognised that steel offered advantages in every direction except, possibly, durability, to begin with its general adoption was checked by the difficulty of obtaining supplies, but in the early eighties this was overcome and many steel ships were laid down. The form of the hull was also the subject of numerous experiments in the constant effort to increase the carrying capacity on the same or smaller tonnage, and for this reason several revolutionary designs were brought forward. One of the most striking and permanent of these was the turret deck steamer which was evolved and built by the Doxford Shipyard of Sunderland. In this type a curve in the side above the water line gave a narrow deck with a broad extreme beam, and for some time it permitted a great economy in dues.

The "Turret" of 1892 was the first ship of this type and was laid down by Messrs. Doxford on speculation but bought by Messrs. Peterson Tate & Co. for the Canadian trade. Other steamship lines took up the turret deck steamer enthusiastically, particularly the Clan Line, but many of its advantages were negatived by the amendment of port and canal regulations and although these steamers were capable of carrying a very large cargo and were excellent seaboats if properly treated, in inexperienced hands they were apt to give trouble and they gradually fell out of favour.

DIESEL SHIPS

The Caspian steamer "Wandal," which was built by Messrs. Nobels in 1903, was the first sizeable ship to be given an internal combustion engine, but in her case it was used to generate electricity for the main drive.

Engines in which the charge was exploded by a hot bulb or an electric spark were found suitable for small craft soon after they had become general in automobiles on land, but their size was strictly limited. In the year 1892 Dr. Rudolf Diesel took out his patent for an engine in which the charge was exploded by raising its temperature by compression while it was still inside the cylinder, and ships propelled by such units, which have been built up to very large sizes and which many consider to be preferable to steam plants, are invariably termed "diesel-engined."

The "Wandal" was followed in 1906 by the "Venoge," a motor barge on Lake Geneva, and in 1910 the motor tanker "Vulcanus" of 1,179 tons marked a great improvement in size. Two years later the motor ship "Selandia" was commissioned by the Danish East Asiatic Company, which is still one of the principal advocates of the diesel engine, and is running successfully to this day. Her dimensions were 370 feet by 53·2 by 27·1 depth of hold, her gross tonnage being 4,950. She was a twin screw ship, each shaft being driven by an 8-cylinder four-stroke cycle engine with cylinders $20\frac{7}{8}$ inches in diameter by $28\frac{3}{4}$ inches stroke, totalling a brake horse power of 2,450 at 140 revolutions per minute and driving her at a speed of twelve knots. She was rigged as a three-masted schooner and the absence of funnel attracted general attention. Its suppression is now quite usual with some owners, while others prefer to run the exhaust from the engines up through funnels and make their motor ships practically indistinguishable from steamers.

After the success of the "Selandia," for although all the early diesel-engined ships had a certain amount of difficulty with their machinery she was a distinct success and very economical, a series of ships was built steadily improving in size, efficiency and economy. War practically held up experimental work in that connection as far as merchant ships were concerned, but the diesel improved rapidly in submarines and the Germans brought it to a very high pitch of perfection. In Great Britain the result of Admiralty experiments were also placed at the disposal of the mercantile engineers at the end of the war. Several submarine diesels were fitted into German cargo ships after the war, their speed being geared down to the efficient speed of the propeller as in the case of the turbine, with satisfactory results.

To begin with the diesel engine was more or less confined to the cargo vessel, but after the war it was realised that its adoption in large passenger vessels would mean a very considerable saving in space and running costs, although the first costs were considerably higher than in the case of the steamer. After several trials in comparatively small ships, in 1924 the "Aorangi" of 17,491 tons was built at the Fairfield Yard on the Clyde for the

Union Steamship Company of New Zealand and has proved most successful on the service between Vancouver and Australia. She was followed in 1925 by the "Gripsholm" of the Swedish American Line, a ship of 17,716 tons designed for service between Sweden and the United States. There was considerable doubt as to the wisdom of building this ship, for the diesel shows to its best advantage on long runs, but she has proved an unqualified success. In the same year a great advance in tonnage was made with the 22,000-ton "Asturias," built at Belfast for the Royal Mail Steam Packet Company, and the diesel-engined passenger liner is now firmly established. Messrs. Harland and Wolff, the builders of the "Asturias," have specialised in a big double-acting Diesel built on the lines of Messrs. Burmeister and Wain of Copenhagen, one of the earliest diesel builders, and have developed high powers.

The "Augustus" of 32,650 tons, built for the Navigazione Generale Italiana in 1927, was the largest motor liner in the world in 1928. In deference to public opinion all these large passenger motor ships have been given funnels, the majority of them two, but the builders have evolved a typical Diesel funnel, short and very stout, which does much to obviate the echo which can prove exceedingly troublesome when the exhaust is carried through a funnel of ordinary design, particularly in fog.

The relative advantages of steamships and motor ships are still the subjects of infinite discussion and argument, each type possessing very real advantages for certain work.

The Still Engine.—In the Scott-Still engine, first fitted in the Blue Funnel Liner "Dolius" of 5,994 tons in 1924, an effort is made to combine the steam and diesel systems, but although a remarkable economy has been obtained this is still in the experimental stage.

ELECTRIC DRIVE

Electric propulsion at sea, the power in that case being generated by the internal combustion engine, was first tried by Nobels in the "Wandal" on the Caspian in 1903, a vessel that has already been mentioned as the first motor ship. The German Navy adopted it in the case of the submarine salvage vessel "Vulcan" in 1907 and it was also tried in 1913 in a Canadian Lake vessel, the "Tynemount," where the current was generated by two Diesel engines of 250 B.H.P. apiece. She was followed by the Swedish "Mjolner," in which the current was generated by two turbines of 450 S. H. P. each. The American Navy, which has since brought the system up to its highest pitch of perfection, first tried it in their steam collier "Jupiter" of 20,000 tons displacement, in which the turbine generator was of the Curtiss type and where the results were so successful that the system has been adopted in their latest and biggest battleships. The "Jupiter" is now the aircraft carrier "Langley." For cruisers and destroyers, however, the United States Naval authorities have found that mechanical gearing is better.

Since the war there has been a growing tendency to favour electric propulsion for merchant ships, particularly in America, and with the benefit of the experience gained in the American Navy it has been possible to install large powers with perfect success. The most striking case is the Panama-Pacific Liner "California," employed on the intercoastal trade between New York and California. She is a ship of 20,325 tons built in 1928, her electric machinery generated by turbines giving her a speed of 18 knots. She is being followed by two sister ships. A similar installation has been chosen for the Peninsular and Oriental Liner "Viceroy of India," launched on the Clyde in 1928, and apparently for the new 1,000-foot White Star Liner under construction at Belfast.

SPECIAL TYPES OF POWER SHIPS

As the steamship improved and as the shipping business became more complicated and exacting, special types came into existence in considerable numbers.

Train Ferries.—The 417-ton steam train ferry "Leviathan," built in 1849 for the North British Railway Company to run across the Firth of Forth from Granton to Burntisland, was the first of a type which has now become quite general and which has been built to large size on several services. Almost at the same time another was built to cross the Tay at Dundee, but both these ferries were later replaced by bridges. In 1878 the Philadelphia and Reading Railroad built their first ferry steamer to run across New York Bay and in the early 'eighties the Danes started a train ferry from Korsor to Nyborg. The idea of a similar service to run across the Straits of Dover has constantly been suggested without success and an ambitious scheme for a train ferry between Sweden and England is now being discussed, but numerous difficulties have arisen in each case and the only train ferry on a large scale in Great Britain is that running from Harwich to Zeebrugge and employed very largely for the carriage of French and Italian fruit to England. The biggest ship of the train ferry type in which the trains run straight on to the rails on the deck of the ship is the "Contra Costa" in California, a wooden vessel with a gross tonnage of 4,483, built in 1914, but big vessels are now building and projected in which the rolling stock is lowered on to the rails by cranes.

Steam Trawlers.—In the early 'seventies several attempts were made to introduce steam trawlers in the South of England, but they were not successful. Some years later a shipping slump caused numerous steam tugs to be laid up and the experiment was tried of using some of these for trawling. Most of these were paddlers, the first being the "Messenger" which made her first trip to the fishing grounds in 1877, but the experience gained in her and other converted ships showed that the paddle was unsuitable for the purpose. Experiments with screw boats were tried in the early 'eighties and were an immediate success, the design developing rapidly and producing some of the finest sea boats afloat. At the present time practically every maritime country has its big fleet of power trawlers and drifters. The internal combustion engine has made great strides in vessels of this type recently and electric machinery has also been tried on occasions.

Icebreakers.—"Eisbrecher I.," launched in 1871, was the first specially designed icebreaker to be built. She was planned on the experience gained a few years previously by a Russian shipowner named Britneff, who reconstructed the bow of the steamer "Pilot" in such a way that she could be driven on to the ice in the hope that she would break it by her own weight. In practice she was too small and light for this purpose, but the idea was appreciated and is embodied in all modern icebreakers, some of which run to a large size.

Tankers.—The increased consumption of oil for various purposes made it necessary to evolve some means of carrying it in bulk instead of in barrels as it had been carried from the earliest days of whaling. The first suggestion was in 1863, when the sailing vessel "Ramsey" had a few tanks built into her hold to carry oil in bulk in addition to stowing barrels in the ordinary way in her 'tween decks. From 1869 to 1872 the sailing vessel "Charles," of 794 tons, was carrying oil in 59 iron tanks which were built into her holds and which completely filled them. The problem of keeping ironwork oil-tight was not then fully understood and these tanks were far too weak, with the result that in the working of the ship under sail constant leaks developed and eventually she was burned at sea. Several other ships were converted in similar fashion, mostly for the trade across the Atlantic to Havre and Antwerp, but they were all failures.

In 1872 the Red Star Line of Philadelphia started a new system by having the steamship "Vaderland" of 2,748 tons built by Palmers on the Tyne with the idea of carrying a large cargo of oil in bulk in addition to her passengers. All the authorities were against this scheme on grounds of safety, and she was used for passenger and cargo only, as were also the "Nederland" of 1873 and "Switzerland" of 1874 which were designed on similar lines. This prohibition of the carriage of oil in passenger vessels exists to-day.

In 1879 Nobels, who have already been noted for their work in building the pioneer motor and electrically driven ship, built a number of tank steamers to carry oil on the River Volga and attained considerable success with them. These steamers attracted some attention at the time, but the idea that oil would be safer in a sailing vessel than a steamer was still generally held and in 1886 the sailing ships "Andromeda" and "Crusader" were fitted

1. Looking along the upper deck of the S.S. "Île de France." Passengers promenading; life-boats seen on both sides of ship
2. Café terrace, comfortably furnished on one of the lower decks of the "Île de France"
3. Large stateroom in the "Berengaria"; every convenience possible has been installed
4. Smoking room, first class, in the "Virginia," Panama Pacific Line steamer, early American period design
5. Spacious dining saloon embodying all features of the modern up-to-date restaurant, "Île de France"
6. Swimming pool for the passengers on board the "Berengaria"

with cylindrical tanks on an improved system for the purpose. Their designers attained a considerable measure of success in making their tanks oiltight, but in the same year the firm which is now Messrs. Armstrong Whitworth and Company and which still makes a speciality of tanker construction, designed and built the first real tank steamer on modern lines.

The "Gluckauf" had a deadweight capacity of 3,000 tons and a speed of 10½ knots, her engines being placed right aft for safety as is still almost invariably done in tankers. Her hull was subdivided into tanks and arrangements were made for pumping them on a principle which is still used.

Since the war a large number of tank steamers have been built, although it is one of the most difficult trades to cater for and to maintain. In spite of numerous experiments it remains almost invariably a one-way cargo, so that the ship has to be exceedingly economical on account of the return journey in ballast. A large cargo is desirable for the ocean route and 13,000 tons deadweight and more is now quite a usual size, while the speed seldom exceeds eleven knots. On account of their tremendous length and unequal strain, the design of these tankers involves very careful considerations of strength and the majority of modern types are built on the longitudinal system, with great attention paid to fore and aft stresses.

Packet Steamers.—When the screw superseded the paddle for overseas work, the older fashion survived in the excursion steamers round the British coast, where shallow draught was generally necessary to get alongside the piers, and in the cross Channel services. The growing Continental trade and the limitations in draught imposed by the French and Belgian harbours brought the paddle packet steamer to a high pitch of perfection in the last days of the 19th century, ships of well over 2,000 tons gross with a speed of 22 knots and excellent seaworthiness being built in considerable numbers, mostly on the Clyde. No more of these big cross Channel paddlers were built after the turbine had proved its possibilities, but many other steamers propelled in this way, much smaller and rather slower, were built for the various excursion routes in the summer. Most of these again were excellent sea boats and were able to perform valuable minesweeping service during the war.

In the United States, however, where the huge inland waterways favour the side wheel, the paddle steamer has been brought up to its highest state of development. The biggest ships of this type in the world are the "Greater Buffalo" and "Greater Detroit," built in 1923 for service on the Great Lakes, each having a gross tonnage of 7,793 and being driven by three cylinder compound engines.

Standardised Ships.—In the early days of the World War mercantile construction was almost completely suspended in Great Britain, Germany and France in favour of warships, but it received a great impetus in the United States. When the German submarine campaign caused an acute shortage of tonnage it had to be resumed in an intensified form in Britain, while from 1917 the Americans launched a shipbuilding campaign unprecedented in the history of the industry. In order to save time and money wherever possible, standardised shipbuilding came into vogue. It had existed within certain establishments for many years, the German yards particularly specialising in certain types and turning out large numbers of sister ships for various owners. During the World War, however, it was carried right through the various countries and in some cases the inland steel works, usually employed on bridge construction and the like, were utilised for fabricated ships with lines as straight as possible which were only put together and launched in the shipyards. Owing to the difficulties of supply many of these standardised ships were given machinery unsuited for their type and the construction of the hull was frequently hasty, so that they have found themselves severely handicapped in competitive trading since the Armistice.

In the United States wood was very largely used, both for full-powered ships and auxiliaries, but there was no time to permit the timber to season and they were built of "green" timber. Similarly a number of vessels of various types—lighters, tugs, tankers, etc.—were built of ferro-concrete, the rapidity with which they could be turned out compensating for their excessive weight in wartime, although only one or two of them survived more than a few months of peaceful trading.

In criticising these war built standard ships there has been a very general tendency to forget the peculiar circumstances in which they were built and the necessity of getting something that would float into the water as quickly as possible. Their utility in competitive trading in peaceful circumstances was a secondary consideration. The United States Shipping Board, a State department formed to run the tonnage so built in America, was left with a large number of ships on its hands for which no purchasers or managers could be found, but many of them have since the peace been converted to Diesel or electric power and their running expenses greatly reduced.

The Cabin Liner.—From the very early days of regular services, the older and smaller units of the various companies were put on intermediate services at reduced prices, and these ships gradually came to be known as cabin class ships. Very few ships were specially built for the class until 1914, when the Canadian Pacific Line commenced a long series with the "Metagama" and the "Missanabie," ships with a gross tonnage of about 12,500 and speed of 16 knots, having accommodation for 520 passengers in the cabin class, paying a fare approximating to the second class fare in the bigger ships, and 1,200 in the third class. Since then the type has been taken up enthusiastically by various companies, particularly on the North Atlantic, until the present development is the "Duchess of Atholl" and her sisters, also owned by the Canadian Pacific Line, having a gross tonnage of roughly 20,000, a sea speed of 17 knots and single reduction geared turbines supplied by oil fired high-pressure boilers which give the remarkable economy of 0·64 lb. of oil fuel per s.h.p. per hour for all purposes.

Fast Cargo Liners.—There has been a noteworthy tendency to build fast cargo liners since the war, ships with a sea speed of 14, 15 and 16 knots, but carrying cargo only to regular schedule. Both steamers and motor-ships have been built for these services and have found great favour with shippers. Great economy in running has been obtained with the result that they have secured a considerable proportion of the trade which was formerly carried by tramp steamers.

High Pressure Steam.—In steamers this remarkable economy has been made possible very largely by the employment of high pressure steam. The Clyde passenger steamer "King George V.," built by Messrs. Denny in 1926 in conjunction with Messrs. Yarrow, the boilermakers, and the Parsons Steam Turbine Company, had the first noteworthy installation apart from unsuccessful experiments made half a century ago. She was a steamer of 791 tons gross, burning coal under water-tube boilers working at a pressure of 550 lb. to the square inch with the steam temperature raised to a maximum of 750 degrees Fahrenheit. This ship considerably exceeded her contract speed of 20 knots on trial and has proved a success in many ways, particularly with regard to economy. But numerous adjustments and alterations have had to be made since her launch.

In modified form high pressure steam has resulted in very considerable economies, both in fuel consumption and weight. Although no steamer has yet been built with anything approaching the 550 lb. of the "King George V.," the general tendency is to increase the pressure both for naval and for mercantile work and 400 lb. is becoming quite usual.

Express Luxury Liners.—The White Star Liner "Oceanic" of 1871 was the first of the modern type of express luxury liner, which attracts more attention than any other type, but which can exist economically only on the direct service between Europe and the United States. The White Star Line had then just been founded for the purpose of engaging in the Australian trade, and for that purpose had bought the name and houseflag of one of the most famous of the clipper ship companies. Events had caused the directors to change their intentions and the first ships were put on service between Liverpool and New York, the "Oceanic" being the pioneer. These ships differed very materially

from the accepted type of screw steamer, having over ten beams to their length and being designed on the somewhat revolutionary lines advocated by the late Sir Edward Harland of Messrs. Harland and Wolff, the Belfast shipbuilders. The tonnage of the "Oceanic" was 3,707 and while she was fully rigged as a 4-masted barque her single screw engines gave her a sea speed of 14·75 knots, and she proved herself an unqualified success after being generally condemned on theoretical grounds by the experts. Three years later the "Germanic" and "Britannic," the latter still afloat as a Turkish Government ship, were built with a gross tonnage of 5,000 and speed of 16 knots.

The Guion Line, which until then had been engaged principally in the emigrant trade, then entered the race for the Atlantic Blue Riband with the "Arizona" of 1879, a ship of 5,147 tons with a sea speed of 16·25 knots. An improved edition of the same design was the same company's "Alaska" of 1881, her gross tonnage being 7,142 and her speed 17·75 knots. In the "Oregon," which was built just before the company got into serious financial difficulties and which eventually sank in collision with a small schooner, the gross tonnage went up to 7,375 and the speed to 19 knots.

The reply of the Cunard Line was the construction of the "Umbria" and "Etruria" at the same establishment which had turned out the big Guion ships, Elder's Fairfield Yard. They were ships of 8,120 tons with a speed of 19·5 knots and they marked the final development of the single screw express liner on the Atlantic. Although they were specially designed to compete with the "Oregon," that ship had passed to the Cunard Line before they were completed.

The next great improvement was the design of the "City of New York" and "City of Paris," when the twin screw system was adopted for express ships. They were built for the Inman Line in 1889 but were better known under the flag of the American Line to which they were transferred in 1893. These ships secured the Atlantic Blue Riband and were the last big Atlantic liners to be built with the old-fashioned clipper stem. When it was desired to transfer them to the American Line Congress only permitted them to hoist the Stars and Stripes on condition that two ships of at least equal tonnage were built in American yards, which resulted in the "St. Louis" and "St. Paul," of 11,630 tons and 21 knots speed, being built in 1895, the first big Atlantic liners to be built in the United States since the 'sixties.

The White Star Line replied to these ships with the "Teutonic" and "Majestic" in 1889, ships which had a great struggle with the "New York" and "Paris" for the Atlantic record. In 1893 the Cunard Line secured the Blue Riband without doubt with the "Campania" and "Lucania" of just under 13,000 tons with a sea speed of 22 knots.

In 1897 the German companies, which had built up a big business in comparative obscurity beside the companies racing for the Blue Riband, came out with the "Kaiser Wilhelm der Grosse" of the North German Lloyd, which lowered the record very considerably. She had a gross tonnage of 14,350 and a speed of 23 knots. Their rivals, the Hamburg American Line, built the 14,500-ton "Deutschland" to compete for the record, but on their experience with her they decided to follow the policy of comfort and good cargo capacity on more moderate speed, a policy which was also followed by the White Star Line after the "Teutonic." The North German Lloyd on the other hand steadily lowered their own record with the three ships which followed in the same series and to the same general design—the "Kronprinz Wilhelm" of 1901, the "Kaiser Wilhelm II." of 1902, and the "Kronprincessin Cecilie" of 1906. Each of these ships marked a further advance in size and speed.

Before the last named could be tried at her best the Cunard Line had built the "Lusitania" and "Mauretania" with the financial assistance of the British Government, which wanted the Cunard Company to remain a purely British concern at a time when the International Mercantile Marine, under the guidance of Mr. Pierpont Morgan, was absorbing company after company. The former was built on the Clyde, the latter on the Tyne, and they differed slightly in minor details. The "Mauretania's" dimensions are 762·2×88×57·1 feet depth of hold, giving her a gross tonnage of 31,938, while her quadruple screw direct coupled turbine engines have a designed shaft horse power of 68,000, intended for a speed of 25 knots. The "Lusitania" was sunk by a German submarine during the war; the "Mauretania" has the unique distinction of holding the Atlantic Blue Riband for 22 years and when 20 years old proving herself capable of steaming at 29 knots to the rescue of a disabled cargo ship.

When these two ships were built their use as auxiliary cruisers by the Navy had a very considerable influence on their design, but experience in the early days of the war showed that they were far too extravagant with fuel for this purpose, although the "Mauretania" and other big and fast ships later proved themselves to be extraordinarily useful both as transports and hospital ships. The Germans had precisely the same experience with their express liners which had been heavily subsidised as auxiliary cruisers.

Maintaining their policy of avoiding excessive speed, the Hamburg American Line answered these Cunarders with the biggest steamers in the world. The first of the series was the "Imperator," now the Cunard "Berengaria." She was launched in 1912, her dimensions being 886·3×98·3×57·1 feet depth of hold and her original gross tonnage 51,969. The second of the series was the "Vaterland" which is now the "Leviathan" of the United States Lines. Her dimensions were increased to 907·6×100·3×58·2 depth of hold, and her gross tonnage was 54,282. It is now 59,957. The third ship was the "Bismarck," now the White Star "Majestic," similar to the "Vaterland" but slightly longer.

Post-war Policy.—Immediately after the war nearly all the lines had to engage immediately in a shipbuilding programme to replace casualties, although shipbuilding prices were at their highest level. The general tendency was to build a moderate-sized ship with good cargo capacity and comfortable passenger accommodation at reasonable rates. The Cunard Line brought out the "Franconia" type of five ships of just under 20,000 tons gross with a speed of 17 knots, while the Hamburg American Line built four ships of the "Deutschland" type, having a sea speed of 16 knots and a tonnage of rather less than 21,000.

This tendency was broken by the Compagnie Générale Transatlantique, which in 1926 built the "Ile de France," a ship of 43,548 tons gross with direct acting turbines of 52,000 s.h.p. and a trial speed of 24 knots. The North German Lloyd, which had built up its fleet steadily since the Armistice, responded by laying down the "Bremen" and "Europa," ships of 46,000 tons each, with a legend speed of 26½ knots on service. They have geared turbines and considerable weight is saved by a boiler pressure of 375 lb. to the square inch, while their design is revolutionary in many features, particularly in the bulb bow under the waterline from which most satisfactory results were hoped. The "Bremen," launched in 1929, beat all Atlantic records, but was outstripped by the "Europa" on her first voyage to New York in March, 1930. Both the White Star and Cunard Lines have planned ships of over 1,000 feet in length in answer to this Continental competition but construction is slow and many of their details have been kept secret. It has, however, been announced that the White Star liner will be given turbo-electric propulsion.

The express Atlantic liner tends to become more and more luxurious to cope with the demands of the first class passengers, but many travellers elect to be carried by the cabin ships at a lower charge. No first class ship can find favour on the Atlantic without all the qualities of a floating hotel—private bathrooms to the majority of the cabins, gymnasia, swimming baths, a long range of public rooms, and such luxuries as a Ritz Carlton restaurant for those who do not care for the ample menu provided in the first class dining saloon. Naturally the prices in such ships are high and their appeal is limited, but there appears to be sufficient patronage for all the ships of the type which the premier lines can afford to build. The cost of each of the 1,000-foot liners which are being built by the Cunard and White Star Lines is estimated at between five and six million pounds.

SHIPBUILDING. Ships have existed from the earliest ages; but it is only in comparatively recent days that the design and building of ships has become a science, more or less exact. Ships have now to perform a great variety of duties; and experience has shown the necessity of a corresponding variety of types and the great progress made in recent years in steel manufacture and shipbuilding and engineering practice has enabled great advances to be made in the size and capabilities of the several types of ships. The duties which a ship is required to perform, the conditions of employment and the general progress in shipbuilding and marine engineering practice, determine her leading features; but whatever the type of ship the fundamental theoretical principles underlying the design are the same.

THEORETICAL SHIPBUILDING

Stability.—A ship floating at rest in still water is in the same condition as any other floating body and the rules of elementary hydrostatics must be satisfied. These are that (1) the weight of the ship must equal the weight of water displaced known as the *displacement*: and (2) the centre of gravity of the ship and the centre of gravity of the water displaced—known as the centre of buoyancy—must be in the same vertical line. It is further necessary that the ship upon being slightly disturbed from its position of equilibrium, should tend to return to that position, when the equilibrium is described as stable. Should the ship on receiving such a disturbance tend to move still farther the equilibrium is unstable: and the intermediate case where she tends to remain in the new position is described as a condition of neutral equilibrium.

Of the various modes of disturbance to which a ship may be subjected it is sufficient for practical purposes only to consider that caused by rotation about a horizontal axis, the displacement remaining unaltered. Such a rotation can in general be resolved by the ordinary statical rules into two rotations about perpendicular axes and it is convenient to consider the question with reference to (1) an axis parallel to the fore and aft M.L. plane of the ship and (2) an axis at right angles to this plane; these rotations result in stability conditions known as transverse stability and longitudinal stability respectively.

Transverse Stability.—In fig. 1 W L is the water-line when upright, and W′ L′ is the waterline when ship is inclined through a small angle θ. The displacement is assumed constant. G is the centre of gravity: B the centre of buoyancy in upright and B′ the centre of buoyancy in the inclined position. The forces acting on the ship are as shown and constitute a couple $W\times GZ=W\times GM\ \sin\theta$. $GZ=GM\sin\theta$ is termed the *righting lever.*

As drawn, the couple tends to restore the ship to the upright and consequently the equilibrium is stable. If G were above M the couple would tend to capsize the ship and the equilibrium would be unstable.

Hence for stability of equilibrium the centre of gravity must be below the point M, and the moment of stability is proportional to GM. When θ is indefinitely small the point M tends to a fixed limit and is then termed the *metacentre,* the distance GM being known as the *metacentric height.* It is found that in ships of ordinary form for inclinations up to approximately 15° the point of intersection of the vertical is through the points B and B′ coincides very nearly with the metacentre, so that within these limits the moment of stability is approximately $W\times GM\sin\theta$.

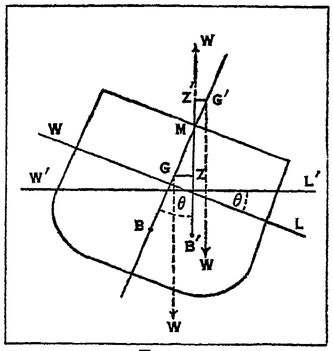

FIG. 1

The position of the centre of gravity can be calculated when the weights and positions of the several parts are known. The position of the metacentre depends entirely on the geometry of the immersed portion of the ship. A simple analytical investigation shows that the axis of rotation must pass through the centre of gravity of the water plane—which point is known as the *centre of flotation*—and that the height of the metacentre above the centre of buoyancy is equal to the moment of inertia of the water plane about the axis of rotation divided by the volume of displacement; with the usual notation, i.e., $BM=\frac{I}{V}$. These quantities, together with the position of the centre of buoyancy are found by the ordinary methods adopted for ship calculations and the position of M in the ship found. Thus by selecting the underwater form any desired value of GM can be obtained; such value differs in various types of ship, experience determining the desirable figure for each type.

Typical values of metacentric height for various classes of ships are as follows:—

Class of ship	Approximate GM in feet
Battleship	5 or more
Cruiser	3 or more
Torpedo boat destroyer	$1\frac{1}{2}$–2
Liner	1 –2
Cargo steamer	2
Tug	$1\frac{1}{2}$–2
Sailing vessel	3 –4
Shallow draught vessel	very large: 12 or more

Changes in metacentric height are caused by alteration in displacement or in the position of the centre of gravity, and it is necessary to investigate the stability in several conditions. The position of the centre of buoyancy and metacentre are readily calculated for several W.L.'s which correspond to calculable displacements; and the position of G for any given condition can be calculated. The results are conveniently shown on a *metacentric diagram* in which the curves of height of metacentres and vertical positions of the centres of buoyancy are set up from a line intersecting the W.L.'s at 45°.

Inclining Experiment.—The calculation of the position of G is a lengthy and laborious process and is inevitably of a more or less approximate nature. When the ship is nearly complete a check is obtained on the position of G by use of the properties of metacentric stability. This is termed an inclining experiment and is carried out by moving a known weight (w) through a known transverse distance (d), thereby producing a couple tending to incline the ship. This couple is resisted by the stability couple of the ship and a position of equilibrium is reached at some angle θ which is directly measured by pendulums. We then have

$$w\times d=W\cdot GM\ \sin\theta.$$

The GM in the inclining condition is thus known at once: the position of M is known from the metacentric diagram and consequently the vertical position of G for this condition determined.

The position of G in any other condition is readily obtained by a simple process of algebraic additions.

Large Inclinations.—The intersection of the two verticals through the centres of buoyancy in the upright and the inclined condition is the fixed point M only when the inclination is small. For larger inclinations it becomes necessary to investigate the matter further. For all practical purposes it is sufficient to assume that the centre of buoyancy remains in the same transverse plane, when the ship is inclined. The conditions are as indicated in fig. 2 and the righting lever is $GZ=GM' \sin\theta$. The point M′ is known as the *pro-metacentre* and it is important to note that in general its position alters with the angle of inclination. The problem now is to determine the value of BM', for which there is no simple formula.

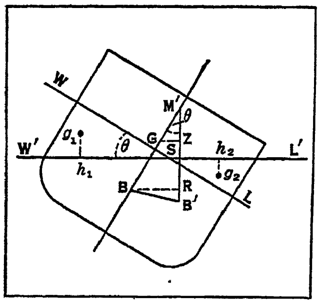

FIG. 2

If v be the volume of either wedge and g_1, g_2 their respective centres of gravity:

Then $V\times BR=v\times h_1h_2$.

Also $GZ=BR-BG \sin\theta$

whence the righting moment

$$W\times GZ=W\left[\frac{v\times h_1h_2}{V}-BG\sin\theta\right].$$

This is known as *Atwood's* formula. Thus the value of the righting moment at any angle resolves itself into evaluating the expression $v\times h_1h_2$. Several methods can be adopted, one of the most convenient being that introduced by Barnes and published in Trans. Institute of Naval Architects 1861.

A different method of approaching the problem has generally been adopted in France; the investigation being due to Reech and first published in his memoir "Construction of Metacentric Evolutes for a Vessel under different Conditions of Lading" (1864). These methods enable GZ to be obtained for a fixed displacement for any angle and the curve obtained by plotting these values as ordinates on a base of angles furnishes a *curve of stability* and a similar curve can be obtained for any desired displacement.

All such methods are cumbersome, and the method now universally adopted for obtaining GZ at large angles of inclination is that described in papers by Merrifield and Amsler in Trans. Institute of Naval Architects (1880 and 1884). With this method in which the work can be expeditiously carried out by the use of the integrator, the value of GZ is obtained for a number of constant angles at varying displacements. The curve obtained for a fixed angle by plotting GZ as ordinates on a base of displacement is known as a *cross curve of stability*: and a similar curve can be obtained for any desired angle. It is obvious that either set of curves can be readily constructed when the other is available. In carrying out these calculations it is necessary to make certain assumptions, the principal of which are that all openings in weather deck and in ship's side up to the weather deck are covered in and made watertight and that all weights in the ship are fixed.

The slope of the curve of stability for small angles, the maximum value of GZ and the angle at which it occurs, and the angle at which GZ vanishes and upon reaching which the ship is about to capsize, determine the character of the curve. Other important factors influence the curve, viz., the freeboard, an increase in which tends to lengthen-out the curve and thus make the vanishing angle larger; and the position of C.G. which affects both the initial stability and the range. To sum up, initial stability is dependent essentially on beam and position of C.G. while range is dependent essentially on freeboard and position of C.G.

A very interesting and instructive theoretical exercise is to plot the curves of centres of buoyancy and of pro-metacentres as the ship turns through 360°. The matter was first fully investigated by Dupin in 1822. Dupin also investigated the properties of the *curve of flotation,* which is the envelop of all possible waterlines for the ship when inclined transversely at constant displacement.

Dynamical Stability.—The dynamical stability of a ship at any angle is defined as the work done in inclining the ship from the upright. Its value is conveniently obtained by integrating the curve of stability, *i.e.,* dynamical stability $=W\times\int_0^\theta GZ\cdot d\theta$, and a curve of dynamical stability on a base of angles is readily obtained.

Sailing Ships.—A ship with sails is subjected to the wind-pressures on the sails and upper works and to the water pressures on the hull. The wind pressure on the sails is dependent on the wind velocity and on the form and area of the sails; and the amount of sail that can safely be carried is contingent upon the existence of large statical stability at moderate angles of heel.

The stability of a sailing vessel is usually estimated by assuming all plain sail to be placed in a fore and aft direction and to be subject to a normal pressure of 1 lb. per sq.ft. corresponding to a wind of about 16 knots. The resultant pressure of the wind is taken as acting through the C.G. of the total sail area, this point being known as the *centre of effort.* The resultant pressure of the water on the hull is assumed to pass through the centre of gravity of the immersed M.L. plane: this point is known as the *centre of lateral resistance.* Then if h be the distance between these points in feet, A the sail area in sq. ft. and α the angle of heel, then the following equation is approximately true.

$$W\times GM\sin\alpha=\frac{Ah}{2240}$$

or

$$\sin\alpha=\frac{Ah}{2240\,W\times GM}.$$

The reciprocal of this expression, *i.e.,* $\frac{2240\,W\times GM}{Ah}$ is a measure of the capability of the ship under sail of resisting heel and is termed *power to carry sail.* Its value varies with the size and type of ship, the value for boats and yachts being 3–4 and in full-rigged sailing ships 15–20. For further information as to the desirable stability requirements for yachts, reference can be made to Dixon Kemp's "Yacht Architecture."

Dynamical stability is of the first importance in sailing ships in order to provide against the risk of capsizing when struck by a sudden gust of wind or a succession of such gusts. By equating the dynamical stability to the work done on the ship by a sudden gust of wind, the heeling effect caused by such a gust is readily found.

Longitudinal Stability.—The problem of longitudinal stability is in all respects similar to that for transverse stability. If L be the length of ship between draught marks it can be readily shown, that, defining the change of trim as the sum of the differences of draught forward and aft the moment to change the trim one inch is given by the expression $\frac{W\times GM_L}{12\times L}$. The effect in changing trim of any longitudinal disturbing moment is then at once obtained.

Stability when Damaged.—When a ship is damaged in the neighbourhood of the W.L. her initial stability conditions will, in general, be adversely affected. Underwater damage may adversely affect stability or may improve it. The resultant condition of the ship will depend upon the extent of the damage and the degree of her sub-division into W.T. compartments; and it is necessary to investigate stability under given conditions of damage to ensure that the ship will not capsize upon receiving damage to the extent decided upon as reasonably likely. For warships in particular it is desirable to know the effect of damage on the flotation of the ship and in the British service it is the practice to supply to ships what is known as a *flooding board* on which is indicated the sinkage, angle of heel, and the effect on trim caused by flooding each W.T. compartment below water in the ship.

Stability in General.—The consideration of the stability of a ship when inclined about a longitudinal and a transverse axis is generally all that is necessary for practical purposes; but the

general theory of the stability of ships abounds in interesting problems in applied mathematics. Of these may be mentioned investigations by Dupin, Guyou and Greenhill, of stability when ship is inclined in any direction; Greenhill's investigation of the stability of a ship carrying oil or molasses; and Froude's and White's investigations of stability amongst waves.

ROLLING OF SHIPS

A ship at sea is subjected to the action of waves which set up rolling, pitching and other oscillatory motions, of a more or less complex character. Of these, in general, rolling is the most important, and it is sufficient in considering rolling to neglect the influence of other oscillations.

Unresisted Rolling.—It is convenient first to consider the ship as rolling in still water and to neglect the influence of resistance; when it follows from a simple investigation that for small angles of inclination the period of roll—the *period* being defined as the time of a single complete oscillation, *i.e.,* out to out and back again—is given by the expression

$$T = 2\pi\sqrt{\frac{K^2}{m \cdot g}}.$$

where K is the mass radius of gyration of the ship about the axis of rotation and m is the metacentric height.

The theory now generally accepted for the unresisted rolling of ships amongst waves is due to Froude, and is based on the proposition that the forces acting on a ship among waves tend to place her normal to the wave sub-surface passing through the ship's centre of buoyancy. To simplify the investigation Froude also assumed that the wave profile was a curve of sines, instead of the trochoid which more nearly represents actual waves, and that the ship was rolling broadside on in a regular series of similar waves of given dimensions and given period. It was also assumed that the ship's rolling in still water was isochronous, and that the period of rolling was given by the theoretical expression already referred to, viz.:

$$T = 2\pi\sqrt{\frac{K^2}{m \cdot g}}.$$

For the reasons underlying the assumptions made and for the complete investigation of the equations of motion, etc., reference can be made to Froude's papers in Trans. I.N.A. (1861 and 1862). It may be stated broadly that the ship oscillates as in still water, but has superposed on these oscillations a series of oscillations governed by the wave-slope and the relation existing between the period of the ship and that of the wave. An interesting case arises when the ship's period is equal to the period of the wave, when at the passage of each successive wave crest and hollow the inclination of the ship is increased, so that but for the effect of resistances and the departure from synchronism at large angles of roll, she would inevitably capsize.

Resisted Rolling.—It remains to consider the practical case of actual rolling of ships in which resistance has important effects. In still water resistance causes a degradation of the amplitude of roll until the ship finally comes to rest. A similar degradation is caused when the ship rolls amongst waves. After the theoretical consideration of unresisted rolling already described, attention was given by Froude and others, first to resisted rolling in still water, and the method adopted was to roll an actual ship in still water to as large an amplitude as could be obtained and then observe the diminishing amplitude at each successive roll until she eventually came to rest.

A curve plotted with number of rolls as abscissae and amplitude of roll as ordinates gave a curve of *declining angles.* From this curve a second curve was made, called the *curve of extinction,* with angles of roll as abscissae and angle lost per swing as ordinates. Particulars of such curves obtained by experiment on H.M.S. "Revenge" can be seen in Sir W. White's I.N.A. paper of 1895. With these curves as data Froude proceeded to investigate the relation between the degradation of amplitude and the resistances causing such degradation. Making the assumption that the resistance to rolling varies as the angular velocity, it is readily shown that the period is slightly increased and the amplitude progressively diminished by the resistance. In actual cases although part of the resistance varies as the angular velocity, part also varies as the square of the angular velocity. This leads to an equation of motion not in general susceptible of analytical solution, but the solution can be obtained by a process of graphic integration. If it be assumed that the motion be simple harmonic then the equation of the curve of extinction can be approximately expressed by the empirical formula:

$$\text{Angle lost per swing} = -\frac{d\Theta}{dn} = a\Theta + b\Theta^2$$

where Θ = extreme angle in degrees reached at any particular oscillation, n the number of oscillations and a and b are coefficients which can be determined in a particular case.

Froude considered that the surface friction and the head resistance of keels and deadwood was responsible for the resistance varying as the second power of the angular velocity and that the creation of a small wave at each roll causing dissipation of energy was responsible for the resistance varying as the first power of the angular velocity. These views have been generally confirmed as the expression for the decrement, viz., $a\Theta + b\Theta^2$ fits the curve of extinction of practically any ship fairly well if the coefficients a and b are judiciously selected. The experiments on "Revenge" referred to above were carried out in the light and in the deep conditions and before and after bilge keels were fitted to the ship.

The outstanding result of these experiments was the unexpected large increase in the value of the "b" coefficient after bilge keels were fitted and other experiments confirmed the result. Mr. R. E. Froude, after experimenting with a deeply submerged plane oscillating in water, found that the head resistance of the bilge keels only accounted for about one-fourth of the energy lost in a single swing due to the increased value of the "b" coefficient; and some cause other than head resistance must be operating to account for the discrepancy. The matter has since been closely investigated in other directions and it is generally agreed that bilge keels become effective not only by virtue of the head resistance developed but by indirectly influencing the streamline motions which would exist if there were no bilge keels. At the same time during the early portion of the swing the bilge keels set in motion a considerable mass of water the energy from which is for the most part dissipated; motion of the ship ahead intensifies this loss and combined with the increase of other resistances at high speeds produces a more rapid extinction. For detailed consideration of this portion of the subject reference can be made to papers of the I.N.A. by Professor Bryan in 1900 and Mr. A. W. Johns in 1905 and 1909.

The problem of resisted rolling among waves was investigated by Froude, who after considering other methods developed and adopted the process of "graphic integration" which is an exact method of determining the motion of a ship, having given the elements of the ship's rolling in still water and the wave-series acting upon her. Reference should be made to Froude's paper in Trans. I.N.A. 1875.

Analytical consideration of the equation of motion shows that the ship has a free oscillation which in time dies out, leaving a forced oscillation in the period of the waves. Actual observation of rolling, however, shows that a ship seldom completely forsakes her own natural period of roll; this is due to departure from exact uniformity in the waves encountered. For consideration of special conditions reference can be made to papers by M. Bertin in Trans. I.N.A. for 1894 and 1895. In a paper read at I.N.A. 1896 Mr. R. E. Froude investigated the probable maximum amplitude of roll when the ship is under the influence of a non-synchronous and non-harmonic swell. Further papers read at the I.N.A. in 1896 and 1898 by Professor Kriloff dealt exhaustively with the whole motion of a ship including pitching and rolling.

Methods of Reducing Rolling.—Considerable attention has been given to the reduction of rolling: in warships to obtain

steadiness of gun platform and in liners to ensure the comfort of passengers. Of all such methods the fitting of bilge keels has been the most important and successful. Attention was drawn by Froude to the great value of bilge keels in diminishing rolling and demonstrated by him in 1892 by experiment with "Perseus" and "Greyhound." These two ships were alike in every essential particular except that bilge keels were fitted to "Greyhound," and it was found that the rolling of "Greyhound" was only about one-half that of "Perseus." Subsequent trials with other vessels substantiated the general conclusions as to the effectiveness of bilge keels.

Another method of reducing rolling in a seaway to which considerable attention has been given is by the use of water chambers. The action is mainly automatic and the motion of the water in the tank is not to be controlled to any extent except that the tank can be put out of action by throttling the motion or by emptying. The first ship fitted was "Inflexible" in which was provided an open rectangular tank extending across the ship. It was tried out at sea by Sir Philip Watts who also experimented on rolling models of "Edinburgh." In essence the method consists in fitting across the ship one or more tanks of such shape that when filled to a suitable height with water the motion of the water from side to side as the ship rolls is such as to retard the rolling. The water chamber reduces the angle of roll chiefly by modifying the righting couple acting upon the ship throughout her rolling; it increases the righting couple which opposes the motion as the ship heels over, thereby reducing the amount of heel and on the return roll it lessens the righting couple and causes the ship to move more slowly than she otherwise would; her angular momentum on reaching the upright is consequently less and she tends to roll less the other way. (*See* papers by Sir P. Watts, Trans. I.N.A. 1883 and 1885.) The tanks were of some use in reducing rolling but were excessively noisy, and extensive use has not been made of them.

In comparatively recent times the idea has been revived in a more elaborate form and the anti-rolling tank first projected by Frahm has been fitted in several ships. This tank is of U form extending from side to side of the ship athwartships and consists essentially of two vertical columns connected by a horizontal tube at the bottom; the water fills the latter completely and about one-half of the vertical tanks. The upper parts of the vertical tanks are connected by an air pipe which is fitted with a valve or throttle by means of which the motion can be controlled. To prevent eddying during motion fixed baffles are arranged at the sides. One set of tanks is fitted near each end of the ship. It can be shown that once the shape of the tank is fixed the period is also more or less fixed and is practically independent of the amount of water.

For further information reference should be made to the paper by Frahm in Trans. I.N.A. 1911 Pt. I: and for the complete mathematical investigation see Mr. Woollard's paper Trans. I.N.A. 1913 Part II.

The general conclusions reached may be summarized as follows:—(1.) The "powerfulness" of the tank, or its capacity for affecting rolling depends principally on the proportion of the ship's metacentric height lost by virtue of free water surface in the tanks. There is also a relatively small hydro-dynamical effect from the inertia of the water in motion from side to side. (2.) The period of the tank depends on its shape, particularly the area of the constricted channel at the bottom; it is almost independent of the amount of water contained and of the degree to which the flow is resisted. (3.) If a ship be likened to a pendulum, the ship and tank are equivalent to a double pendulum; to get the best results the period of the tank should be slightly less than that of the ship. (4.) The tank is effective in stopping heavy rolling but is useless or disadvantageous among very short waves and should then be put out of action. The U tank has been fitted in some liners and warships but as it does little to reduce moderate rolling it has not made much headway. More recently the adoption of an anti-rolling tank, open to the sea, has been projected. The use of anti-rolling tanks in general has not found much favour and they are open to practical objections.

The idea of using a weight moving from side to side to prevent or reduce rolling at sea was tried by Sir John Thornycroft in a yacht of about 230 tons displacement, the moving weight being 8 tons. The weight was worked automatically by apparatus controlled by two pendulums, one of which—a long period pendulum—remained vertical and the other—a short period pendulum—placed itself perpendicular to the effective wave slope. The apparatus is heavy and cumbrous, but is sound in principle, and effected a reduction in rolling of about one-half in the yacht in which it was fitted (*see* Trans. I.N.A. 1892).

Diminution of rolling by the use of the gyroscope was investigated by Dr. O. Schlick and an arrangement fitted in the S.S. "See-bär." The ship was of 56 tons displacement having a metacentric height of 1·64 ft. and a period of roll of 4·14 seconds. The flywheel of the gyroscope weighed 1,100 lb. and was 1 metre in external diameter, revolving at 1,600 revolutions per minute. The axis of the flywheel was initially vertical, and the casing containing the wheel was capable of revolving about a horizontal athwartship axis, the centre of gravity of the apparatus lying slightly below this axis. A brake was fitted to control the longitudinal oscillation of the casing. When the wheel was revolving and the axis held by the brake, no effect was produced on the motion of the ship; but when the axis was allowed to oscillate freely in the middle-line plane the period of roll was lengthened to 6 seconds, but no other extinctive effect was obtained. By suitably damping the longitudinal oscillations of the gyroscope, however, by means of the brake, a large extinctive effect resulted, and during the trials made, the apparatus practically stopped all rolling motion. (For detailed account of the principle of action, details of the gear, and description of trials, *see* Trans. I.N.A. 1904 and 1907.)

A further development of the gyroscopic method is the apparatus devised by Sperry. This consists essentially of two main gyroscopes rotating and precessing in opposite directions; the plane of precession being horizontal and the axes of rotation normally athwartships. The two gyroscopes thus combine against roll but they neutralize each other as far as yawing is concerned. An auxiliary gyroscope maintains true horizontal. The principle of action can be stated briefly as follows:—As soon as the ship has rolled through a very small arc, an electrical contact connected to the auxiliary gyroscope is established making a current which actuates the precession motors of the main gyroscopes and these continue working until the ship is again horizontal. The gear has been fitted in several ships, one being the U.S. Navy transport "Henderson" of 10,000 tons and it has been generally satisfactory. One of the later gyroscopic installations is that in the U.S. liner "Hawkeye State" of about 20,000 tons displacement. The total weight of the equipment is of the order of 200 tons.

Pitching and Heaving.—The laws governing pitching are identical with those for rolling but there are important numerical differences, the principal of which are due to the fact that the longitudinal stability is very large and period consequently short and that the resistance is relatively great. To keep decks dry it is important that the ship should pitch with the wave instead of remaining level and thus shipping water. In a large number of vessels the period for pitching is approximately one-half of that for rolling but the maximum angles are considerably less. An exhaustive series of experiments on mercantile ship models in waves has been carried out at the N.P.L., *see* Trans. I.N.A. 1922. Reference can be made to this paper for details.

When a ship is in still water her natural period of oscillation in a vertical direction known as *dipping* oscillation is given by the expression $2\pi\sqrt{\frac{12\,W}{gT''}}$ where W is the displacement in tons and T'' the tons per inch immersion. When the ship is amongst waves these dipping oscillations may synchronize with the waves and set up considerable vertical oscillations known as *heaving* and defined as the actual rise and fall produced in a seaway. Heaving motions are favourable to seaworthiness since waves are less likely to break on board.

Dipping oscillations are frequently caused by pitching or rolling giving rise to uneasy motion. This action may be of importance in ships whose sides near the waterline have a considerable slope to the vertical since any rolling motion is then accompanied by vertical oscillations of the centre of gravity. Uneasy rolling of a peculiar character also results from interference between the rolling and pitching movements of a ship. This takes place when the centres of gravity of the wedges of immersion and emersion for moderate angles of heel are separated by a considerable distance longitudinally.

RESISTANCE AND PROPULSION

A ship is propelled by the thrust on the propellers; and when the ship is in steady motion the thrust on the propellers must equal the resistance of the ship. It is convenient to consider first the resistance of the ship assuming the propeller to be removed and the ship to be towed at uniform speed through undisturbed water. The power thus expended in towing the ship is termed the *effective horse power.* This power is considerably less than the power exerted by the propelling machinery at the same speed; and the relation between the two—known as the *propulsive coefficient*—and the effect of the propellers on the resistance of the ship will be discussed below under *Propulsion.*

Resistance.—In an incompressible perfect fluid it can be shown that a body of "fair" form moving uniformly at a considerable depth below the surface does not experience any resistance to motion. For purposes of investigation it is convenient to impress upon the whole system a velocity equal and opposite to that of the body, which then becomes motionless in a uniform stream of the fluid. The motion is then termed steady. The particles of fluid move along paths termed "stream lines," and the surface formed by all the stream lines passing through a small closed contour is termed a "stream tube." The motion of the fluid in a stream tube is such that the flow along the tube is constant, and that Bernoulli's energy equation is satisfied. The other conditions affecting the flow and determining the forms of the stream lines are purely geometrical and depend on the form of the body. The motion in a perfect fluid flowing past bodies of a few simple mathematical forms can be investigated analytically but in the general case the forms of the stream lines can only be obtained by approximate methods.

Components of Resistance.—In actual practice the motion of a ship on the surface of the sea is subject to resistance through various causes. Frictional resistance results from the rubbing of the water past the surface of the hull and in the great majority of ships is responsible for a large proportion of the total resistance. Eddy resistances are caused by abrupt changes of shape and any local discontinuities such as shaft brackets. Resistance due to wind is experienced on the hull and upper works. Also, the stream line motion causes a diminution in the relative velocity of the water at the ends of the ship; this decrease of velocity is, in accordance with the energy equation, accompanied by an increase in pressure resulting in an elevation of the surface of the water at those places. Thus a wave is formed at the bow and stern, which requires an expenditure of energy for its maintenance and adds to the resistance. Eddying is caused by abrupt beginnings or endings, particularly the latter, in the water lines and underwater fittings. The resistance from this cause is usually small except with full forms when it may become relatively large.

Air resistance in itself is generally of little importance on a calm day; and the prejudicial effect of wind and rough weather on the speed of ships is largely due to the action of the waves and currents and the irregular motions of the ship. The combined effect on the ship's speed is frequently large but indeterminate. Valuable investigations on ships are being made under sea conditions to ascertain quantitative effects and some useful results have been recorded in Trans. I.N.A.

The difference between the total resistance and that due to skin friction is termed the residuary resistance, the principal component of which is the resistance due to wave-making. The action of the waves is such as to distort the stream lines near the hull, and the form of the waves is in turn affected by the frictional wake; it follows that the frictional and wave-making resistances of a ship are to some extent mutually dependent. It is convenient to neglect the interaction of these constituents and treat each independently; and practical justification for this assumption is furnished by the close agreement between the results of experiments on models and on ships, where the proportion of frictional to total resistance differs greatly.

Wake.—Since the action and the reaction of the water pressure on the hull of a ship are equal and opposite, forward momentum is generated in the water such that the increase of momentum per second is equal to the total resistance. The water participating in the forward movement is termed the *wake*; and the portion of the wake in the vicinity of the propellers has a considerable effect upon the propulsion of the ship. Experiments on a model were made by Mr. Calvert (Trans. I.N.A. 1893) to determine the wake velocity. The magnitude of the wake was measured at various positions in the length and its maximum velocity was found to be 0·67 times the speed of the model. Abreast the screw the mean velocity ratio over an area of the same breadth as the model and of depth equal to the draught was 0·19 ft. of which about 0·05 ft. was ascribed to frictional resistance. A theoretical investigation by Froude in Reports of the British Association 1874 suggests the approximate extent of the frictional wake and its velocity distribution based on the equality of the resistance to the momentum added per second. It is to be noted that when a ship is propelled in the ordinary way at uniform speed the momentum generated in the sternward race from the propeller is equal and opposite to that of the forward wake due to the hull; the motion of the water as a whole thus consists of a circulatory disturbance advancing with the ship but having no linear momentum.

Frictional Resistance.—Practically the whole of the resistance at low speeds and a considerable proportion of it at higher speeds is due to surface friction. Its magnitude is usually estimated from the results of experiments made by towing planks coated with various surfaces. The most important of such experiments were those made in 1871 by Froude in the experiment tank at Torquay, to obtain the laws of variation of resistance with the speed, the length and the nature of the surface. A dynamometric apparatus by which the planks were towed was used to register the resistance; the planks were given a fine edge at each end to avoid eddy-making and were fully immersed in order that no waves should be formed. For the complete results see Reports of the British Association 1872 and 1874; but the following extract gives a summary, n being the index of the speed at which the resistance varies, A the mean resistance per square foot of surface over the length stated, and B the resistance per square foot at the after end of the plank; both A and B refer to a velocity of 10 ft. per second in fresh water.

Length of Surface in Feet

	2 ft.			8 ft.			20 ft.			50 ft.		
	n	A	B	n	A	B	n	A	B	n	A	B
Tinfoil .	2·16	·30	·295	1·99	·278	·263	1·90	·262	·244	1·83	·246	·232
Paraffin .	1·95	·38	·370	1·94	·314	·260	1·93	·271	·237	..	..	..
Varnish .	2·00	·41	·390	1·85	·325	·264	1·85	·278	·240	1·83	·250	·226
Fine sand	2·00	·81	·690	2·00	·583	·450	2·00	·480	·384	2·06	·405	·337
Calico .	1·93	·87	·725	1·92	·626	·504	1·89	·531	·447	1·87	·474	·423
Medium sand .	2·00	·90	·730	2·00	·625	·488	2·00	·534	·465	2·00	·488	·456
Coarse sand	2·00	1·10	·880	2·00	·714	·520	2·00	·588	·490	..	..	..

These results are in accordance with the formula:—

$$R = fwS\frac{V^n}{2g},$$

R being the frictional resistance, S the area of surface, V the speed, w the density of the water, f a coefficient depending on the nature and length of the surface, and n the index of the speed; the values of f and n are obtained from the above table. The resistance then varies as the density of the water, but is independent of its pressure; it diminishes as the length of the surface increases on account of the frictional wake which reduces the relative velocity between

the water and surface towards the after end. The index n is 1·83 for a varnished surface equivalent to the freshly painted hull of a ship. When applying the data to ships of length greater than 50 ft. the coefficient B denoting the resistance 50 ft. from the bow, is assumed to remain unaltered at all greater distances astern. The velocity of rubbing is assumed equal to the speed of the ship, any variation due to stream-line action being neglected. The wetted surface S when not directly calculated can be estimated by approximate formulae.

Many other reliable experiments have been made on the resistance of smooth planks from time to time. The results obtained are all in reasonable agreement with Froude's, with the exception of those due to Gebers, in whose experiments particular care was taken to obtain an exceptionally smooth surface and to eliminate parasitic resistance. In general, coatings of varnish and many other compounds give about the same resistance if the surface is reasonably smooth and hard; and it is assumed that the coefficients for the varnished planks can be applied to the freshly painted ship's surface. Alternative extrapolation of the plank data has been proposed by Baker and also by Gebers. These give ship resistances somewhat less than Froude's, but so far Froude's results are almost universally used with practical success. The subject is continuously under investigation and experimenters are seeking to formulate, if possible, a more rigorous basis for assessing the skin friction resistance of ships. The plank results are intended for application to a ship with clean surface. After the ship has been some time out of dock the growth of weeds and barnacles causes a considerable increase in skin friction resistance.

Wave Resistance.—The resistance due to wave making, inconsiderable at low speeds, is of importance at moderate speeds and constitutes the greater portion of the total resistance at high speeds. As already stated it is convenient to regard the problem as one of steady motion in a stream flowing past a stationary ship. The stream tubes, originally of uniform width, become broader on approaching the bow of the ship and attain their greatest breadth close to the stem. Near amidships the tubes become smaller and enlarge again near the stern. The changes in size and velocity in the stream tubes lead to corresponding alterations of pressure in accordance with the energy equation, and these alterations appear as elevations and depressions of the surface forming the statical wave system. If this were a permanent system, no resistance to the motion of the ship would result. But the surface disturbance is subject to the dynamical laws underlying the propagation of waves; and consequently the wave formation differs from the statical wave, the crest lagging astern of the statical wave crest, and the ship is followed by a train of waves whose lengths are appropriate to the speed. The energy in the wave system travels backward relative to the ship at one-half its speed; and the resistance to the ship's motion is due to the sternward drain of the wave energy which has to be replaced by work done on the ship.

The form of the wave system is not susceptible of complete mathematical investigation; but the circumstances are approximately realized and the conditions considerably simplified when the actions of the bow and stern of the vessel are each replaced by the mathematical conception of a "pressure point." This consists of an infinitely large pressure applied over an indefinitely small region of the water surface; it is assumed to move forward in place of the ship through still water, or, equally, to be stationary in a uniform stream. The resulting wave system has been investigated by many investigators, including Lord Kelvin. Recently the theory has been still further developed; and it is possible to calculate the wave resistance of simple ship-shape forms by purely mathematical methods with a fair degree of accuracy. All the results are in agreement in many respects with those of actual observation for ships and models.

The figure, reproduced from Froude's, Trans. I.N.A. 1877, shows the bow-wave system obtained from a model; this is illustrative of that produced by ships of all types.

Two types of waves accompany a ship—(1) diverging waves having sharply defined crests placed in echelon, the foremost wave alone extending to the ship; (2) transverse waves limited in breadth by the diverging crests and reaching the sides of the vessel throughout its length. Since the bow diverging waves are not in contact with the ship, except at the bow, the energy spent in their maintenance travels away from the ship and is lost entirely. A diverging wave system of similar form but smaller dimensions attends the passage of the stern; and the resistance due to the diverging system of waves is the sum of its components at the bow and stern, increasing with the speed, and depending considerably on the shape of the bow and stern.

On the other hand the combined transverse bow and stern wave systems produce a stern wave in contact with the ship, and the resistance due to the resultant transverse wave system depends on the phase relation between the waves of the two systems. The effect of the combination on the wave resistance was investigated by Froude (Trans. I.N.A. 1877) by means of experiments on a series of models having the same ends, but in which the length of parallel middle body was varied. At constant speed, curves of residuary resistance on a length base consisted of humps and hollows, the spacing of which was constant for a given speed and approximately equal to the wave length appropriate to the speed; the amplitude of the fluctuation diminished as the length increased. For a given length the residuary resistance in general increased at a high power of the speed; but it was also subject to a series of fluctuations whose magnitude and spacing increased with the speed. A full analysis was made by R. E. Froude in 1881, and showed that a reduction in resistance occurred when the echo of the bow wave crest coincided with the trough of the stern wave; and conversely that the resistance was abnormally increased when the crests of the two systems coincided. The fluctuation in the resistance was smaller when the length of middle body was greater, owing to the greater degradations of the bow wave system at the stern through viscosity and lateral spreading. With very considerable lengths of middle body, the height of the bow wave system at the stern was insufficient to produce interference or to affect the resistance.

From these experiments certain deductions were made as to the dependence of the speed of a ship (V knots) on its length (L feet) and the slightly different length (L^1) between component bow and stern waves; these deductions are to a great extent confirmed by experience with ships of all classes, and may be stated thus:—for economic propulsion at a speed V the length L of the ship should be generally equal to or slightly less than V^2, corresponding to the "favourable" value of 1·2 of the ratio $\frac{V^2}{L^1}$. Vessels of extremely high speed such as torpedo-boat destroyers are an exception, the value of $\frac{V^2}{L}$ being then frequently as great as 4, which approximately coincides with the highest "favourable" value of $\frac{V^2}{L^1}$. These early experiments by Froude were especially valuable in directing attention to the important influence of length of ship on resistance; and his conclusions have been verified and amplified by Taylor, Baker and other experimenters in more recent times.

Law of Comparison.—The complex nature of wave resistance renders any simple estimate such as that for frictional resistance, impossible of general application. There is no simple law connecting wave resistance with size, form and speed. The effect of size alone can be eliminated by means of the "principle of similitude" enunciated by Newton, and the law of comparison is the application of this principle to the resistance of ships. To W. Froude is due the credit of making the application, which he did in the following terms:—

"If the linear dimensions of a ship be n times those of its model, and the resistances of the latter be R_1, R_2, R_3, · · · at speeds V_1, V_2, V_3, · · · , then the resistances of the ship at the corresponding speeds, $V_1\sqrt{n}$, $V_2\sqrt{n}$, $V_3\sqrt{n}$ · · · will be R_1n^3, R_2n^3, R_3n^3, · · · and, therefore the effective horsepowers at corresponding speeds are increased in the ratio $n^{7/2} : 1$."

This law is applicable to the residuary resistance but not to frictional resistance, the laws governing which so far as is known do not satisfy the conditions underlying the principle of similitude stated above. Consequently in applying the law of comparison to ships and models where the linear ratio is considerable, the residuary resistance alone should be compared by that means, the frictional resistance being independently calculated for ship and model. When the ships compared do not differ considerably in linear dimensions, the law may be extended to total resistance without appreciable error. Before the law of comparison could be accepted as applicable to ships it was necessary to test it practically and the first tests of this kind were made by W. Froude on H.M.S. "Greyhound" for the Admiralty, the results being recorded in Trans. I.N.A. 1874.

"Greyhound" was towed at a number of speeds, draughts and trims and the resistance, speed and other data carefully measured. Experiments were also made on the model under corresponding conditions. Similar, but much less exhaustive experiments were made by Yarrow on a torpedo boat (*see* Trans. I.N.A. 1883). In each case the measured resistance of the ship was greater than that deduced from the model experiments, particularly in "Greyhound"; but having regard to the deteriorated condition of the surface of the hull it was considered that the agreement was close enough to justify the method adopted for powering ships. This method or its equivalent with modifications in detail has been used ever since, and is practically justified by the results obtained by ships on speed trials. There are, however, certain unexplained inconsistencies in converting the results deduced from models to the ship scale which are allowed for by empirical factors based on experience. These require further experimental elucidation. The adoption in quite recent years of means of ascertaining the thrust exerted by the propellers of ships on trials may help in clearing this up. Other experiments have been made, notably some by Kempf at Hamburg on long cylinders, as a result of which in 1923 an alternative basis for assessing the skin friction of ships was proposed. Further experiments are in progress by Kempf, and the results of these and other efforts should afford valuable data for assessing the true skin friction of ships.

Model Experiments.—As a result of the "Greyhound" trials the accepted method of estimating the horse-power required for a new ship is by running a scale model under corresponding conditions in an experiment tank fitted and equipped for the purpose. The law of comparison is applied to the residuary resistance, or, if used for the total resistance, a "frictional correction" is made. In 1871, W. Froude constructed a tank and suitable apparatus at Torquay for the British Admiralty. In 1886 a new tank was inaugurated at Haslar from the designs and under the supervision of R. E. Froude, such improvements being introduced as experience at Torquay had shown to be desirable. Similar establishments have been instituted by several foreign governments and by some private firms. One of the more recent and up-to-date tanks is that at Teddington forming part of the National Physical Laboratory. This tank was opened in 1911: it is used for general research and is available for undertaking private work required by shipbuilding firms. A brief account of some of the earlier experiment tanks with their equipment is given by Dr. Glazebrook in a paper in Trans. I.N.A. 1909.

Experimental Results.—Some records of the experiments made at the various tanks have appeared from time to time; a few of those made at the Admiralty tanks have been published through the I.N.A. The "Greyhound" experiments have already been mentioned; other papers of fundamental importance to which reference can be made are those recording the "Merkara" results 1876; experiments on the effect produced on wave-making resistance by varying the length of parallel middle body, 1877; papers in 1888 and 1892 on the "constant" system of notation of results of model experiments used at the Admiralty Experimental Works; and some results of a systematic series of model experiments by R. E. Froude in 1904.

The rapid growth in numbers, size and speed of merchant ships in the present century led to the establishment of the Teddington Tank. Many valuable papers dealing with the resistance, form and other properties of merchant ship types are recorded by G. S. Baker and his staff in the Trans. I.N.A. and other societies. Other experimenters in this country and abroad have also published valuable results. The experiments made cover a wide field and include not only resistance and propulsion but such matters as manoeuvring, rolling and pitching; and in general give guidance on a number of special points in design, information regarding which could only be obtained on full scale with great expense and labour.

When the resistance has been obtained from a model experiment, or deduced by the law of comparison from data obtained with a vessel of similar type, the effective horse-power required is known; and by adopting a suitable value for the propulsive coefficient based on the model screw propeller efficiency and other factors the indicated or shaft horse-power is determined. If model experiments or data for exactly similar ships are not available, one approximate method of estimating the power which is commonly used is expressed by the formula—

$$\frac{(\text{Speed})^3 \times (\text{Displacement})^{\frac{2}{3}}}{\text{I.H.P.}} = C,$$

C being called the Admiralty coefficient. The value of C varies considerably and care must be taken that the values selected for comparison are appropriate to ships of similar type and of corresponding lengths and speeds and also type of machinery.

Another method of obtaining approximate estimates of the power required for ships of ordinary types is from curves of resistance drawn on a base of simple functions of the speed, length and displacement, the curves being passed through the spots obtained from a large number of results of model experiments with different classes of ships. Curves of this character have been constructed by Admiral D. W. Taylor, U.S.N. and A. W. Johns (*see* Trans. I.N.A. 1907). By the use of such curves the residuary resistance, or residuary horse power is obtained; the frictional resistance being calculated independently.

Apart from model experiments on the actual design under consideration the most serviceable method of estimating power, and one capable of very general application is to use the results of a methodical series of model experiments. These consist of a series of experiments on systematic variants of a parent form or forms. The first of such a series was carried out by R. E. Froude, and the results published in Trans. I.N.A. 1904. Subsequently Taylor in his book "Speed and Power of Ships," and G. S. Baker in papers in Trans. I.N.A. 1913 and later, greatly increased the range of type ship. The curves thus obtained, used with discretion, are most valuable to a designer of all types of ships. Reference can be made to the records referred to for very interesting details and particulars of various sizes and forms of ships. The value of such curves is greatly enhanced by the fact established experimentally that the resistance of a ship of given length and displacement depends primarily on the shape of the curve of transverse areas, the maximum beam and the shape of the waterline. If these features are maintained the shape of section, profile and other features can be varied over wide limits without appreciable change of resistance.

Shallow Water.—When ships are run at high speeds in comparatively shallow water a considerable change takes place in the resistance and power corresponding to a particular speed. As depth of water decreases the stream lines tend to two dimensional instead of three dimensional flow. This accentuates the stream line variation of speed and pressure and increases the frictional resistance and also the eddy making due to the discontinuous motion set up. The more rapid variation of pressure also increases the wave making if there is any. As the water becomes shallower there is an increase in the wave length appropriate to a given speed which entails considerable alteration in the wave pattern. In particular the speed at which conjunction of wave length takes place is diminished and the "hump" in the resistance curve occurs at a lower speed. Consequently at speeds above middle of "hump" resistance is diminished and at those below middle of "hump," increased by shallowness of water. There are other factors affecting the situation such as the increased local disturbance

immediately surrounding the ship, and the modification to the increase of frictional resistance referred to above caused by the large dimensions of the wave accompanying the ship.

In addition to the foregoing considerations, which relate to the shape of the ship, the restricted nature of the flow also affects the performance of the propeller, often prejudicing its efficiency; further the speed of rotation of the shaft and consequently the power exerted may be affected, resulting in an increase in the loss of speed. In general, shallowness of water causes a reduction in speed, but for high speed ships such as torpedo boat destroyers, there may be a reduction in resistance at top speeds due to the change in wave formation, and as a result on certain shallow water speed trial courses there is an appreciable increase in the obtainable speed. The phenomenon is so complex that recourse must be made to experiment data to estimate the quantitative effect in any specific case. Model experiments have proved most useful in this respect and results of experiments covering a large range of conditions are available. Some results of trials of actual ships in various depths of water have also been published and reference should be made to papers in Trans. I.N.A. and other shipbuilding societies for further information.

Similar, but generally less intensified effects are produced if a ship is proceeding along a channel of restricted breadth. In practice the matter is generally of small importance, as restrictions are laid down as to the speed at which ships are allowed to use such channels. An extreme case of the effect of shallowness of water sometimes occurs when towing boats or barges at speeds large enough to cause a solitary wave of translation. The resistance at larger speeds is then often less than at low. Scott Russell was the first to draw attention to this phenomenon and special canal boats have been built to take advantage of it.

Acceleration.—When the speed of the ship is not uniform the resistance is altered by an amount depending on the acceleration, the inertia of the ship and the motion of the surrounding water. The effect may be regarded as equivalent to a virtual increase in displacement; and in the "Greyhound" experiments Froude found this increase to be about 20% of the displacement. This value is probably approximately correct for all ships of ordinary form.

PROPULSION

The action of a marine propeller consists fundamentally of the sternward projection of a column of water termed the propeller race. The change of momentum per unit time of this water is equal to the propeller thrust which during steady motion is balanced by the resistance of the ship. If we assume that the passage of the ship does not affect, and is uninfluenced by, the working of the propeller, and neglect all losses of energy except that due to the astern motion of the race, it can be shown that the maximum efficiency is $\frac{2V}{V+v}$ where V is the speed of the ship and v the sternward speed of the propeller race relative to the ship. The quantity $v-V$ is termed the *slip* and $\frac{v-V}{v}$ *the slip ratio* S. It follows that the maximum theoretical efficiency is given by the expression $\frac{1-S}{1-\frac{1}{2}S}$.

In the ideal case then the best result is obtained when the sternward velocity imparted to the water is small; that is, when the propeller acts upon as large a body of water as possible. The efficiency will be small if the slip is large. These tendencies are broadly confirmed in practice but they are modified by the losses incidental to the particular form of propulsive agent adopted. These additional losses are caused by friction of the propelling surfaces, rotation or deflection of the propeller race, shock and turbulent flow. The foregoing considerations apply to propulsion by oars, paddle wheel, hydraulic jet and to the screw propeller. The use of oars and paddle wheels is now generally confined to small vessels in sheltered waterways and the hydraulic jet propeller owing to internal losses and other factors has up to the present not been employed except for rare and special purposes. Passing reference may be made to propulsion by sails, ships with aerial propellers and the experimental rotor ship. Such ships are relatively few in number and importance.

The screw propeller is by far the most extensively used especially for seagoing ships and the remaining remarks herein have reference to this form of propulsion. If v be the apparent speed of advance of the screw propeller, that is the product of the revolutions and pitch; and V the speed of the ship carrying the propeller, then the slip is $v-V$ and the apparent slip ratio is $\frac{v-V}{v}$. This notation corresponds to that previously used, $v-V$ being then defined as the absolute velocity of the race. The pitch of the propeller divided by its diameter is termed the *pitch ratio.*

The theory of the action of the screw propeller has been the subject of consideration by many investigators. Professor Rankine in Trans. I.N.A. 1865 assumed that the propeller impressed change of motion upon the water without change of pressure except such as is caused by the rotation of the race. Sir G. Greenhill, Trans. I.N.A. 1888 assumed conversely that the thrust is obtained by change of pressure, the only changes of motion being the necessary circumferential velocity due to the rotation of the screw, and a sufficient sternward momentum to equalize the radial and axial pressures. This idea was further developed by R. E. Froude in 1889 who concluded that the propeller probably obtained its thrust by momentarily impressing an increase of pressure on the water, which eventually results in an increase of velocity about one-half of which was obtained before and one-half abaft the screw. A lateral contraction of the race accompanies each process of acceleration. These general conclusions have been in some degree confirmed by experiments carried out by D. W. Taylor (Proceedings of the American Society of Naval Architects, etc., 1906) and by Professor Flamm, who obtained photographs of a screw race in a glass tank, air being drawn in to show the spiral path of the wake. Professor Burnside (Proceedings London Mathematical Society 1918) considered the problem mathematically and confirmed some of R. E. Froude's results; he also took into account in a general way the effect of the proximity of the stern of the ship.

The problem has also been attacked from an entirely different angle and a theory was propounded by W. Froude in which the action of each elementary portion of the blade surface is separately estimated from the forces on planes moved through water at various speeds and at different angles of obliquity (*see* Trans. I.N.A. 1878). The investigation is of importance though it does not completely represent the actual conditions; for the deductions from a small element moving through undisturbed water are applied to the whole blade; the disturbance of the water when a blade reaches it and the consequent effects of each element on adjoining elements and of one blade on another are not taken into account. The momentum theory of R. E. Froude has been strikingly confirmed by some exhaustive experiments in a wind channel; and it is found that when the velocity deduced from this theory combined with certain interference factors is applied to the blade element theory of W. Froude in the light of modern experiment data, good agreement is obtained with actual practical results in the case of narrow bladed screws such as air propellers.

In recent years the general application of the circulation theory to hydrodynamical problems has resulted in the conception of the vortex theory of the screw propeller. This theory when more fully developed promises not only to clarify the physical nature of propeller action but to assist the quantitative estimating of propeller performance. The large wide blades used in marine propellers and the confused nature of the water flow at the stern of a ship make the application of theory to all marine screw propeller problems extremely complicated.

Experiment Results.—The complicated nature of screw propeller problems was recognized early and recourse was made to model experiments for information on thrust and torque of propellers of various proportions at different speeds and revolutions. These experiments have necessarily been made on a small scale; but some which have been made on larger propellers have sug-

gested that the scale effect if any is not large; and it is generally assumed that the results of model experiments on propellers can be applied to ship propellers in accordance with the law of comparison, no correction being made for skin friction. The most important sets of experiments published covering the proportions of screw propeller met with in practice have been made by Froude, Taylor, Durand and Schaffran. A paper by Taylor in Transactions of the American Society of Naval Architects and Marine Engineers 1924 shows that these experiments made on different sizes of models in different parts of the world practically corroborate each other. The experiments of R. E. Froude cover a very complete range and the results can be used for most practical problems. (*See* Trans. I.N.A. 1908.) The thrust horsepower is given by Froude in the following formula:—

$$H = \cdot 003216 D^2 V^3 \times B \frac{p+21}{p} \times S \frac{(1-\cdot 08S)}{(1-S)^2}$$

where H is the thrust horsepower, V speed of advance in knots and D the diameter in feet; p is the *effective* pitch ratio calculated from the revolutions for zero thrust. For full sized screws Froude considers this is 1·02 times the face pitch ratio; for modern screws it is probable that the ratio should exceed 1·02. The "blade factor" B depends only on the type and number of blades; its value for various "disc area ratios," *i.e.*, ratio of total blade area (assuming the blade to extend to the centre of shaft) to the area of a circle of diameter D is given in the following table:—

Disc area ratio	·30	·40	·50	·60	·70	·80
B for 3 blades elliptical	·0978	·1050	·1085	·1112	·1135	·1157
B for 3 blades, wide tip	·1045	·1126	·1166	·1195	·1218	·1242
B for 4 blades, elliptical	·1040	·1159	·1227	·1268	·1294	·1318

Reference should be made to the paper for curves of efficiency obtained.

Interaction Between Ship and Screw.—In the foregoing theoretical and experimental consideration it has been assumed that the propeller is advanced into undisturbed water, which is very different from the conditions existing behind the ship. The vessel is followed by a body of water in complex motion called the "wake." It is assumed that this water has a uniform forward velocity V^1 over the propeller disc, V being the speed of the ship; the speed of advance of the propeller is then $V-V^1$; and the expression $\frac{V^1}{V-V^1}=w$ is termed the *wake value*. The propeller acts generally as a screw advancing into undisturbed water at speed $V-V^1$ and the real slip is $v-(V-V^1)=v-\frac{V}{1+w}$; w is in general a positive fraction so that the real slip is greater than the apparent slip $v-V$; and real slip must be taken into account in the design of propeller dimensions.

The influence of the screw also extends sufficiently far forward to cause a diminution of pressure on the after part of the ship, thereby causing an increase in resistance. The thrust T, exerted by the screw working behind the ship must be sufficient to balance the tow rope resistance R. This increase of resistance as well as this diminution of pressure is conveniently expressed as a fraction t of the thrust exerted by the screw, whence it follows that $T(1-t)=R$. The power exerted by the propeller or the thrust horsepower is proportional to $T\times(V-V^1)$; the effective horsepower is $R\times V$ and the ratio of these two,

$$\frac{RV}{T(V-V_1)}=(1-t)(1+w)$$

is termed the ***hull efficiency***. The hull efficiency value does not differ greatly from unity with different positions of the screw. An account of an interesting series of experiments to determine the values of w and t is given by W. J. Luke, Trans. I.N.A. 1910.

The total propelling efficiency or propulsive coefficient is the ratio of the effective horsepower (RV) to the indicated or—in turbine driven ships—the shaft horse power. Its value is generally of the order of 0·5. In some recent ships devices such as the contra-propeller have been fitted. In essence this consists of an addition to the hull in front of, or abaft, the propeller, of blades to guide the water to, or away from, the propeller; thus eliminating the rotary motion in the race. Some gain in efficiency is obtained in certain cases, particularly for single screw vessels. Such gain in efficiency is wholly or partially offset by the increased resistance due to the fixed blades themselves and the device is probably of greater value in the case of propellers of large slip and consequently low efficiency.

Cavitation.—The phenomenon of cavitation arises when there is interference with the natural flow of water to the screw. It is accompanied by excessive slip and reduction in thrust and consequently very much reduced efficiency. The diminution of pressure accompanying the acceleration of the water ahead of the screw may in certain circumstances be sufficient to bring about these conditions. Such circumstances arise when the depth of immersion is small and consequently the original pressure low, when tip speed is excessive and when the blade area is relatively small in relation to the thrust. Some experiments were carried out on T.B.D. "Daring" by S. W. Barnaby in 1894 for an account of which and the results obtained *see* Trans. I.N.A. 1897. Later experiments have shown that the circumstances referred to above all have their effect, the critical pressure causing cavitation varying to some extent with the type of ship and with the details of the propeller.

STRENGTH

A ship in a seaway is subjected to variable forces, which induce stresses in the pieces and their connections which make up the hull structure. Most of the forces depend on the action of the sea and cannot be predicted with precision; and at the same time the hull structure is so complex that a quantitative theoretical analysis of the stresses in the parts is in general of value only for comparative purposes. Such comparisons with the results of experience give the only real guide as to the adequacy of the strength of new ships and to the proper distribution of the minimum quantity of material necessary.

Longitudinal Bending.—The greatest straining actions to which vessels of ordinary proportions are subject, are due to inequalities in the longitudinal distribution of the weight and the buoyancy. In the standard calculations the ship is regarded as a beam—(1) on a trochoidal wave of length equal to that of the ship and height $\frac{1}{20}$ of the length, with the crest amidships this condition is known as "hogging." (2) On a similar wave with the trough amidships, the "sagging" condition. The ship is balanced on the wave to satisfy the necessary elementary conditions of equilibrium and curves of buoyancy and weight per foot run plotted on the base of length. The resulting curve obtained by plotting the differences of the several ordinates of buoyancy and weight gives the curve of loads. By integrating this curve a curve of shearing force is obtained, which integrated in its turn gives the curve of bending moment. The conditions of equilibrium ensure that the end ordinates of the shearing force and bending moment curves are zero. The maximum bending moment, frequently expressed as a ratio of the product of the ship's length and displacement, occurs near amidships.

The stresses at a transverse section due to bending are obtained from the usual beam formula $\frac{p}{y}=\frac{M}{I}$; M being the bending moment, I the moment of inertia about the neutral axis, y the distance from the neutral axis and p the intensity of stress. In calculating I, only the continuous longitudinal portions of the structure are assumed effective and a deduction from the area of material in tension is made for rivet holes. The stresses thus obtained vary considerably with the type and size of ship. It is clear that the actual straining actions on a ship necessarily vary with the type, and the stresses allowable calculated on a uniform basis of applied forces must vary accordingly. With regard to size, the larger the ship there is less likelihood of meeting waves

as long as herself, and the proportion of height to length of the largest waves is generally less than that assumed. (For particulars of waves actually observed reference may be made to a paper by Dr. Vaughan Cornish, Journal of Royal Society of Arts, 1912.) For these reasons greater calculated stresses are allowable in large ships than in small or moderate sized ships. For small ships a limiting stress of 6 tons per sq.in. is frequently adopted, with an increase to 8 tons per sq.in. for portions in tension where high tensile steel is used. For large ships the calculated stresses frequently exceed 8 tons per sq.in. compressive and 10 tons per sq.in. tensile.

The validity of the assumption made that the ordinary theory of bending is applicable to the case of a ship was tested and confirmed in 1903 by experiments made on H.M.S. "Wolf" by Sir John Biles. (*See* Trans. I.N.A. 1905.) The experiments were made both in still water and at sea, the extension or compression of the structure at various points being measured by strain indicators. As a result of these experiments it may be said in general that the stresses corresponding to any particular external conditions closely agree with those calculated on the usual theory of bending; but the waves encountered during the sea trials were such that the maximum stress then obtained was considerably less than that in the condition assumed in the standard calculations.

Several refinements for calculating stresses among waves have been suggested, none of which have come into general use. Some of these are the Smith correction (Trans. I.N.A. 1883), and the modifications due to heaving and pitching and rolling oscillations (*see* Trans. I.N.A. 1890, 1896, 1898). In addition to the direct stresses resulting from longitudinal bending, shearing stresses are experienced which in some cases are appreciable. Such stresses reach a maximum at or near a quarter of the length from either end, and at the height of the neutral axis. It is sometimes necessary to give special consideration to the thickness of plating and the connections in this neighbourhood.

Transverse Bending.—Stresses due to transverse bending may be of importance in certain cases; and some means of comparing the transverse strength of vessels is desirable. In a ship well subdivided by transverse bulkheads it is difficult to determine how far the stresses at intermediate sections are influenced by the neighbouring bulkheads, positions at which transverse stiffness is very great indeed. But by taking a section midway between two bulkheads assumed far enough apart to have no influence on the section considered, a method of comparison has been worked out. For further information reference can be made to papers by Dr. Bruhn in Trans. I.N.A. 1901, 1904 and 1905.

Local Stresses.—In addition to the stresses due to longitudinal and transverse bending, there are numerous local stresses for which provision must be made. These include stresses caused by water pressure, heavy blows from the sea on side, deck and upper works, reactions of moving parts of machinery, blast from gun fire, etc. The supports provided are determined by experience and by the requirements of the particular vessel.

It is important that discontinuities and abrupt changes in the distribution of material should be avoided so as to maintain as uniform a distribution of stress over any section as possible. Where large openings have necessarily to be cut, "compensation" is introduced by adding material near the edge of the opening.

Vibration.—A ship like any other elastic structure has a natural period of vibration; and when synchronizing vibrations from whatever cause are impressed on the ship very marked vibration may result. The principal causes of vibration in a steamship are:—(1) The reciprocating parts of the engines, if unbalanced cause vibrating forces and couples in a vertical plane. In twin screw ships torsional oscillations in transverse planes may also result when the engines are working in opposite phase. (2) The rotating parts of the engines cause vertical and horizontal oscillations; and variation in crank effort also tends to produce torsional oscillation particularly in single or two-cylinder engines. (3) Unbalanced propellers produce vibration principally at the stern. (4) The uneven resistance which a propeller experiences during its revolution gives rise to vibrations. This condition results when (1) the propeller blades pass too close to the hull; (2) when the propeller breaks the surface of the water; and (3) when the flow of water to the propeller is imperfect, due either to "cavitation" or the screening effects of shaft and propeller supports. (5) Various items of auxiliary machinery set up independent vibrations.

The adoption of the steam turbine has eliminated many of the causes of vibration referred to above. In general it can be said that vibration in a ship can only be avoided by removing its cause; it not infrequently happens that the addition of further stiffening results in increased vibration.

Reference can be made to papers in Trans. I.N.A. of Dr. O. Schlick (1884 to 1901), of Mallock (1895) and of Nicholls (1924).

Steering.—The information available on the steering and manoeuvring qualities of ships is largely due to the results of trials with British warships. These include observations of the paths when turning under different angles of helm, at various speeds, with and without assistance from the propellers, and with variation in certain features of the hull which influence steering. One of the first attempts at plotting the curve traversed by a ship under the action of her rudder, and the position of the ship at any instant with reference to that curve was made by Sir P. Watts in 1877 on H.M.S. "Thunderer." Similar experiments were carried out on "Yashima" (Trans. I.N.A. 1898).

When the path of the ship is plotted, the bow of the ship is nearer to the centre of the circle or curve in which she turns, than the stern. The ship may be regarded as going ahead and turning or pivoting about a point well forward in the middle line; this is termed the "pivoting point" and the middle line is, at this point, a tangent to the curve concentric with and similar to that described by the centre of gravity of the ship. The angle between the middle line and the tangent to the curve traced out by the centre of gravity is termed the "drift angle." The maximum distance that the ship's centre of gravity travels in her original direction after the helm is put over is termed the "advance"; and the perpendicular distance between the original line of advance and the ship's position after turning through 16 points is known as the "tactical diameter."

It is convenient to investigate the forces acting on the ship in three stages, (1) when the helm is put over, (2) when the ship has finally picked up her circular course, and (3) the intermediate stage when the ship is accelerating but yet has gained some of her rotational velocity. The character of the forces acting during (1) and (2) can be ascertained, and the type of motion under the complex conditions represented by (3) will consist of a gradual replacement of motion at (1) by that at (2).

As soon as the helm is put over the first effect is to alter the stream line motion at the stern. The stream lines against and in front of the rudder are expanded so that their velocity is reduced and pressure increased. This leads to a force on both rudder and deadwood; and the eddying behind the rudder causing a reduction of pressure accentuates the effect. The net result is that a considerable force acts at the stern, the lateral component of which tends to turn the ship, and the component in fore and aft direction adds resistance to the ahead motion of the ship. The proportion of this force due to the deadwood is unknown, but in many modern ships in which the deadwood is considerably cut away this force is small. The portion due to rudder pressure can be calculated from the results of experiments on plates moving obliquely through the water. This force varies with the shape of the rudder and approximately as its area, the angle of helm and the square of the speed; and can be expressed by the formula, $P=KAV^2$ where K depends on the angle of helm and the shape of the rudder. At the maximum helm angle (usually 35°) K is about 1·2; but when applying this a liberal allowance should be made for the reduction of V due to resistance under helm. In actual practice the old formula—

$$P=1\cdot 12AV^2\sin\theta$$

where P is the force in lbs., A the area of rudder in sq.ft., V the speed of the ship in feet per sec. increased by a percentage to allow for propeller race and θ the angle of helm, has been found to give good results at maximum helm angle. Both the lateral and angular

movements of the ship are accompanied by the motion of a mass of water which may be regarded as virtually increasing the mass and moment of inertia of the ship.

The handiness of a ship is mainly dependent on the relation between the moment of rudder pressure for a given angle, and the virtual moment of inertia. If the inertia is comparatively large, the ship will turn slowly under helm. Unhandiness is usually experienced at low speeds when rudder pressure is small, and in shallow water when the virtual inertia is increased by the reduction of the flow of water from one side of the ship to the other. Improvement in such cases has been obtained in certain ships with unbalanced rudders by filling in the after deadwood, the loss from the increased inertia being more than compensated by the greater turning moment due to the pressure on the deadwood.

When the ship is turning steadily in a circle the forces acting are the pressure on rudder and deadwood, the centrifugal force, the thrust of the propellers, and the pressures on the hull. The pressure on the rudder is now less than when the helm is first put over, both by virtue of the fact that the effective rudder angle is less, and that the speed of the ship has decreased.

Heel When Turning.—When the helm is first put over, the pressure on the rudder causes a small inward heel. As the rotational speed of the ship increases the small inward heel is succeeded by a steady outward heel, caused by the couple formed by the centrifugal force and the lateral resistance diminished by the (usually) small couple due to the rudder pressure. If when turning, the helm be put quickly amidships, the opposing couple due to rudder pressure is removed, and the outward heel is momentarily increased. Instances have occurred of ships with small stability and comparatively large "rudder couple" capsizing through this cause.

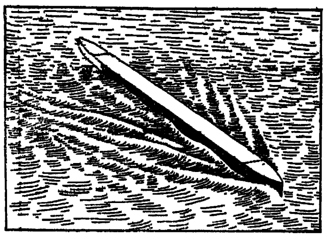

Fig. 3

Types of Rudders.—Rudders used in ships are of two general types (1) unbalanced, and (2) balanced.

The unbalanced rudder, supported at its forward edge, is in stable equilibrium when amidships; and for this reason and its simplicity of construction is preferred when the force required to put the rudder hard over is sufficiently moderate to enable steering to be performed by hand or by an engine and gear of moderate size. For high speeds and large manoeuvring powers the unbalanced rudder is generally unsuitable; and balanced rudders, in which about one quarter of the area is usually placed before the axis, are adopted in order to reduce the force required and the work done to obtain large angles of helm. A balanced rudder is unstable amidships, and if left free, comes to rest at a moderate angle on either side of the middle line. Unbalanced rudders, extending up to, or above the waterline and comparatively narrow longitudinally, are generally fitted in the merchant service (*see* figure 4). Somewhat greater efficiency when using small or moderate angles of helm is obtained with rudders of this type, as for a given pressure on the rudder, the turning moment on the rudder and consequently the power required in the steering gear is less. For fast liners a type of balanced rudder is sometimes adopted (*see* figure 5).

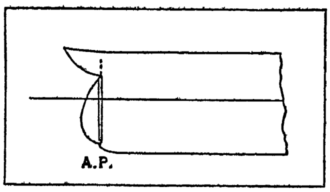

Fig. 4

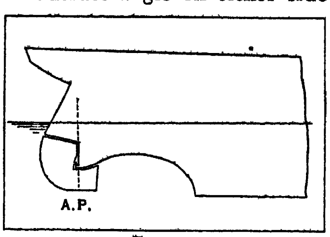

Fig. 5

For warships where the steering gear has to be kept below waterline for protection, broader and shallower rudders are adopted; and for the reason above stated balanced rudders are now practically universal in warships (*see* figure 6).

When a ship is going astern manoeuvring is performed with some uncertainty and additional rudders have sometimes been fitted at the bow; these are generally for use in confined waters where it may be necessary to go astern for a considerable period. Rudders of special form and characteristics such as the Kitchen rudder and the Flettner rudder, have been fitted to some modern vessels.

Experimental Results.—Experiments have been made to ascertain the effects of angle of helm, time of putting helm over, and draught and trim of the ship, on the turning properties of the vessel. In general it is found that the tactical diameter diminishes with increase of helm angle. In ships having unbalanced rudders and hand steering gear considerable time is required to put the helm over at full speed; consequently the tactical diameter and the advance are greater at high speeds than at low speeds. With power worked steering gear with which the helm can be put hard over in from 10–20 seconds at any speed, the speed is found to have little influence on the path described when turning. In the case of torpedo boat destroyers a marked increase in tactical diameter and in advance occurs at high speeds. A moderate variation in mean draught has little effect, but additional trim by the stern results in a greater space being required for turning.

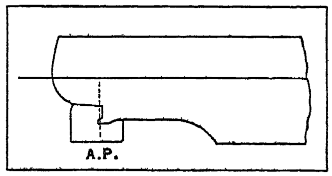

Fig. 6

By working one propeller ahead and the other astern the space required for turning may be shortened, but the time of turning is frequently increased. The path described is generally tortuous in character and depends on the relation between the revolutions of the propellers. In a single-screw ship, with the propeller well immersed, the upper blades experience greater resistance to rotation than the lower blades; hence a right-handed screw tends to turn the ship's head to starboard, and starboard helm is necessary. The reverse is occasionally experienced when the upper portion of the screw is incompletely immersed.

PRACTICAL SHIPBUILDING

Design.—In order that a naval architect may be in a position to prepare a design for a new ship he must first be informed as fully as possible of the requirements which he is to meet. These include the trade or service on which the ship will be engaged; the important features that it is desired to embody (*e.g.*, in a warship the armament and protection to be carried); the speed and endurance to be aimed at, and any limitations in dimensions or cost. In the case of a British warship design the requirements are laid down in the first place by the naval staff. The Director of Naval Construction then prepares outline or sketch designs complying as nearly as possible with these requirements; and after full discussion one of these designs is selected and approved. This design is then worked out in detail, and complete drawings and specifications prepared.

The problems of naval design differ in many respects from those occurring in connection with merchant ships (*q.v.*). Usually the most important consideration is that of weight; for it is necessary to obtain the greatest possible offensive power, defensive qualities and speed in as light and small a ship as practicable. This has led to many interesting developments in structural design; materials of high elastic strength are employed wherever possible, and scantlings are cut to the greatest possible extent consistent with safety. Many fittings and fixtures, and even minor portions of the hull, are made of aluminium alloy or other light materials; and great progress has been made in designing the arrangement of structure so that the material is disposed, as far as practicable, where it is most effective in contributing to the strength of the ship. The importance of this can be realized when it is remembered that in a high-speed ship every ton saved enables the ship as a whole to be lightened by about three tons. The designer's experience is also called upon to dispose the armament so as to be as effective as possible in all directions, and avoid mutual interference by gun blast, to ensure that such protection as is carried shall shield the vitals of the ship for a minimum expenditure of

weight, and to arrange the main and auxiliary machinery so that it encroaches as little as possible on other portions of the ship, particularly those devoted to the accommodation of the personnel and the stowage of ammunition. The form of the ship is largely determined by consideration of the minimum resistance at high speed; in addition adequate stability has to be provided under all conditions (including the cases when the ship has been damaged by gunfire or after attack by mine or torpedo) and the trim and seaworthiness of the ship rendered satisfactory.

The information prepared by the naval architect and supplied to the shipbuilders consists usually of a sheer drawing showing the form of the ship, a profile, various sections and a plan of each deck showing the general arrangement, and the structural sections. With these is a complete specification laying down the materials to be used and their scantlings, and containing a description of all internal arrangements, the fixtures, fittings and stores to be supplied, and the trials to be finally carried out.

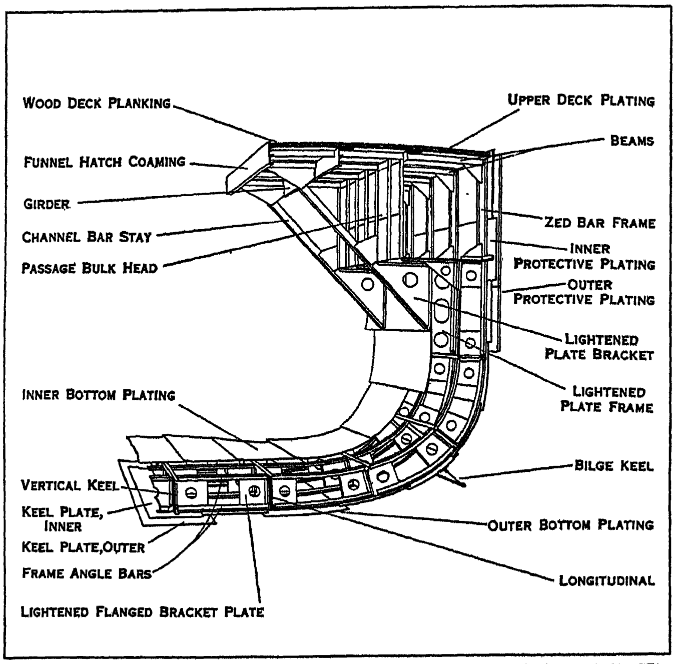
The method adopted for designing a ship cannot be described here at length. It may be observed, however, that the process is tentative, approximate dimensions, form and horse-power being first assumed and the design worked out sufficiently to ascertain whether it meets the requirements. If it fails to do so, or if any defects are revealed, the dimensions, etc., are altered and the process repeated until a design is obtained which satisfies the conditions imposed. The success of the final design depends on the skill and experience of the naval architect, who has to base his plans on his knowledge of existing ships, whilst introducing such improvements as he is able, having regard to progress in materials and machinery and more accurate knowledge of the conditions of service.

Materials.—Ships are in general built of mild steel, which is a ductile material, easily worked, differing entirely from the hard and brittle steels from which tools are made. Its ultimate strength is about 28 tons per square inch. High tensile steels are used largely for important parts of the structure of warships and liners; their strength varies from 33 to approximately 40 tons per square inch. The stem, stern frame, rudder frame, hawse pipes, etc., are generally made of cast steel (26 tons per square inch or less), cables, davits and similar fittings of wrought iron (22 tons), whilst naval brass, gunmetal or phosphor bronze are used for many internal fittings. All materials used are subjected to a variety of tests before being worked into the ship in order to ensure that the quality of material is up to the standard required.

Structural Arrangements.—The steel used in ship construction is worked in the form of plates or rolled sections which are generally angle bars or channels (⊏). They are connected together by rivets, hammered or pressed hot; and the joints are designed so that the strength of the connection is as nearly as practicable equal to that of the material it connects. In addition a large number of joints have to be made watertight or oiltight. This is ensured by closely spacing the rivets so as to draw the plates or bars well together, and by caulking the edges. The latter operation consists of splitting the material at or near the edge, and, using a tool like a cold chisel, hammering the split portion hard against the adjoining plate or bar. This effectively prevents the passage of oil or water between the two surfaces; but with thin plates it is sometimes supplemented by inserting between the bearing surfaces of the plates a "stopwater" consisting of tape steeped in composition.

Cruiser.—The structural arrangement of a typical warship is illustrated by the perspective drawing of a cruiser (fig. 7). The various portions of the structure are lettered and indicated on the diagram. The vessel has two distinct skins or bottoms, viz.: the outer bottom which forms the outside of the hull and transmits the water pressure to the general structure of the ship, and the inner bottom which is also watertight and whose function is to save the ship if the outer bottom is damaged or pierced. In this vessel the thickness of the outer bottom is one inch at or near the keels and behind the outer protective plating at the sides, and slightly less on the bilge. The inner bottom, though thinner, is also worked so as to assist the longitudinal strength of the structure. The space between the two bottoms, termed the double bottom, is utilized as far as possible for the stowage of oil fuel and reserve feed water.

The inner and outer bottom are connected together by two systems of frames (shown in the diagram)—longitudinal and transverse. The former are worked continuously throughout the central part of the ship in order to contribute as effectively as possible to the longitudinal strength; this system of framing, with the



FROM "MANUAL OF SEAMANSHIP" VOL. II BY PERMISSION OF THE CONTROLLER OF H.M. STATIONERY OFFICE

FIG. 7.—MIDSHIP SECTION OF SMALL CRUISER

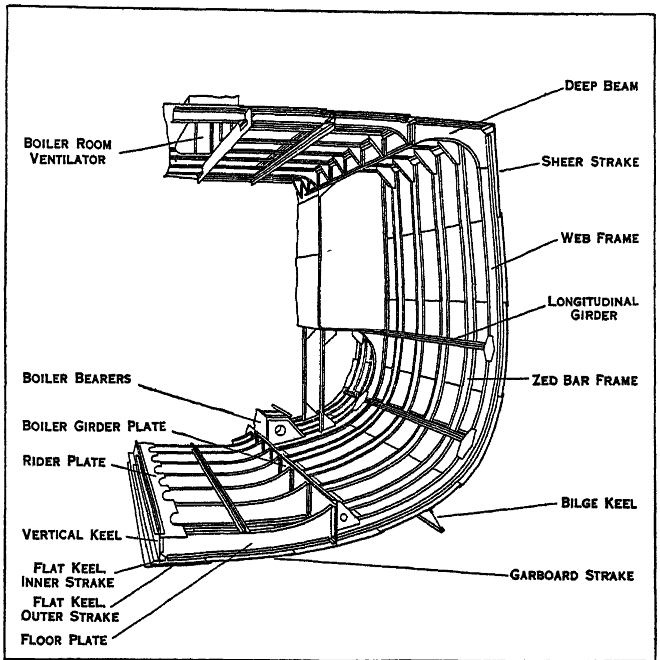
longitudinals predominant, is an important feature of the structure of all large warships. The frame at the middle line—termed the vertical keel, is specially strengthened in order to resist the stresses undergone when the vessel is in dock. The transverse frames (spaced about 4 feet apart) are of minor importance and are worked in short lengths between the longitudinals. Those shown in the figure consist of angle bars and bracket plates stiffened at the edges and lightened by holes; in another system of construction frequently adopted the two brackets are replaced by a single plate lightened by holes which are long enough to permit access through them. Certain of the longitudinal and transverse frames are made watertight or oiltight so as to subdivide the double bottom into a number of cells, which are useful for stowage purposes, and, moreover, limit the ingress of seawater in event of the outer bottom being damaged.

The upper deck is formed of steel plating sheathed with wood and supported by beams worked transversely and slotted through the longitudinal girders shown. These girders with the deck plating (which is thickened amidships) are of great importance in connection with the longitudinal strength; and in some ships they have been increased in number and the beams correspondingly reduced. An interesting feature shown on the diagram is the bilge keel which is fitted in order to reduce the ship's rolling in a seaway. At the ends of the vessel the system of construction is considerably modified, the principal framing being transverse and the double bottom being no longer worked. Adequate watertight subdivision is still provided by the watertight bulkheads and decks, of which the former are more closely spaced than amidships.

In larger warships—battleships and battlecruisers—the system of construction does not differ in principle from that described above for a cruiser. The thickness of plating is greater and the scantlings in general are heavier; and there are several decks which are supported by pillaring (or bulkheads), extending down from deck to deck to the inner bottom where the loads are finally balanced by the water pressure transmitted through the framing. The armour instead of forming a portion of the structure (as in the cruiser shown) consists of separate hard plates bolted to the

ship's side, which is recessed for the purpose; the framing beneath is frequently strengthened in order to support the heavy localized weight. In other respects the structure of a battleship and that of a cruiser are generally similar.

Destroyer.—The destroyer construction is different from that of a cruiser, for there is no double bottom and the important framing is worked transversely and closely spaced (about 21 inches). Owing to the disproportionate weight of machinery which these



FROM "MANUAL OF SEAMANSHIP" VOL II. BY PERMISSION OF THE CONTROLLER OF H.M. STATIONERY OFFICE

FIG. 8.—MIDSHIP SECTION OF A DESTROYER

vessels have to carry, the lower part of the framing is adapted to form supports to the boilers and engines; in the ship illustrated the ordinary frames are interrupted and replaced near the middle line by heavy floor plates. Deepened or "web" frames are worked at intervals in order to provide adequate transverse strength and stiffness. Each frame is connected to a beam supporting the deck above.

The longitudinal frames, which are generally slotted over the transverses, are few in number; but they render valuable assistance to the general as well as the local strength by stiffening the thin plating in their vicinity and preventing it from buckling under a compressive load. They are of particular importance under the deck where they form an integral and valuable portion of the structure which would otherwise be too severely stressed in a seaway. The thickness of the shell plating amidships is in places as small as 0·17 inch; together with the deck, vertical keel and all parts contributing to the longitudinal strength it is made of special quality steel capable of withstanding high stress without injury.

Sloop.—The structure of this well-known type of naval auxiliary craft generally resembles that of a light mercantile ship. The framing is transverse and closely spaced (21 inches). The thickness of the shell plating is about ¼ inch.

Submarine.—The structure of an "L" class submarine is designed primarily to resist the water pressure when submerged. Except for the vertical keel and the local supports to machinery, the framing is therefore wholly transverse and is fitted in the form of rings spaced about 21 inches apart. The thickness of the main hull plating is about ½ inch, and that of the ballast tanks ¼ inch. The transverse strength is supplemented by the bulkheads fitted at intervals.

Watertight Subdivision.—An efficient system of watertight subdivision is particularly important in all classes of warships; for without it any degree of damage below the waterline would lead to the withdrawal of a ship from action, if not to its ultimate loss. In arranging the subdivision it is necessary to localize the influx of water due to small damage, *e.g.*, perforation by fragments of bursting shell, as well as to provide against large damage due to running aground, or being struck by a torpedo or mine. For this reason fairly minute subdivision is required; the main transverse bulkheads (which in merchant ships constitute the whole, or nearly the whole, of the watertight partitions below the "freeboard deck") are supplemented in warships by minor transverse and longitudinal watertight bulkheads; moreover in general, every deck and flat is made watertight. By these means the buoyancy, as well as the stability of the ship is preserved; and if due care has been taken to maintain the watertightness of the various bulkheads, etc., a warship should be able to continue in action after being holed in a large number of places.

It may happen that the injury to the ship, although insufficient to sink her, may lead to a large heel or trim, which would prevent the ship being manoeuvred in action or her guns being fired. To remedy this, means are provided for correcting heel and trim by flooding compartments on the opposite side or end of the ship; suitable compartments are selected for this purpose, and large valves fitted so that the spaces may be quickly flooded when desired. Information is also supplied to the commanding officer on the effect of flooding each compartment, so as to enable a rapid decision to be made in emergency as to any flooding that may be desirable. An important feature of the subdivision of warships is that the main transverse bulkheads are made as far as practicable *intact*. They are not pierced by doors or any other fittings except the necessary electric leads and power pipes, which are placed as high as possible, and, whenever it can be arranged, above the waterline.

Ventilation.—The fittings of warships include those used in direct connection with the armament of the ship (*see* also ORDNANCE: *Naval*), the steering gear, the watertight hatches and doors, the arrangements for pumping, flooding, draining and fresh and salt water supply, the anchor and cable arrangements, the ventilation and many others. It is impossible in the space available to give even a brief description of these fittings or of the installations of which they form part, but the principles underlying the ventilation system of a modern warship will be outlined. In the living spaces of the ship, and in the ordinary storerooms, magazines, etc., it is of the greatest importance that a definite supply of fresh air should be available.

On the other hand, in compartments such as washplaces, latrines, stores where food is kept, and auxiliary machinery compartments—in short in any spaces where foul or overheated air is generated—the first consideration is to remove this air directly overboard and not allow it to penetrate into other parts of the ship. This is effected by fans which exhaust from the spaces in question and deliver the exhausted air into the open. The air required to replace that exhausted is allowed to enter as it will through hatches or doors; although not usually fresh it is sufficiently pure for supply to the spaces for which this "exhaust" system of ventilation is adopted.

In the main engine rooms a combination of both systems is employed; the heated air is removed by large exhaust fans and the fresh air supplied by smaller fans and also allowed to enter naturally through hatches. In the boiler rooms the supply of fresh air to the furnaces ventilates also the compartments themselves. In order to obviate the passage of air trunking as far as possible through watertight bulkheads a large number of small fans are required; in a modern cruiser about 70 fans are fitted for the ventilation of the ship (*i.e.*, in addition to those for the main machinery spaces), and they are capable in the aggregate of supplying and exhausting about 100,000 cubic feet of air per minute.

As regards the arrangements in the spaces themselves, experience has shown that the most successful method is to fit both supply and exhaust high up in the compartments. The fresh air, owing to its greater density, sinks soon after entry, flows over the floor of the space and finally drives out the lighter foul air which has risen. A vigorous movement of air is required under tropical conditions, whereas in cold climates the contrary is the case. This difficulty is overcome by controlling the speed of the fans, so as to vary the quantity of air they supply, and by providing means for

altering the direction and amount of the supply at any point. Steam heaters are also fitted near some of the fans, so that, when necessary, the air supplied may be warmed to a comfortable temperature before it is distributed in the ship. Natural ventilation by cowls, windsails, etc., although used extensively in mercantile vessels is only used in warships for small spaces situated near the open and when required under tropical conditions as an auxiliary to the ordinary ventilation. SHIPBUILDING: MERCANTILE. As a ship is a most complex engineering structure, the process of design requires considerable experience and skill, allied with sound judgment. When a shipowner orders a new vessel he must in the first instance have a clear idea as to the size and type and the other properties desired in order to suit the particular trade in which it will be engaged. These requirements will include the weight and space required for cargo, the number of passengers and type of accommodation for them, the speed to be attained, and the distance to be run without replenishing the fuel supply. One important factor which must not be omitted is the permissible draught of the ship, since the depth of water available in many harbours is limited. In addition it is desirable to decide in which Classification Society, if any, the vessel is to be classed, since this will determine the details of the scantlings to be employed. It is also necessary to decide whether the method of propulsion is to be by steam engines —either reciprocating or turbine or a combination of these—or by an oil engine. The choice of machinery depends upon many considerations, chiefly of an economic character, and it is by no means easy to decide which will be the most suitable to meet given conditions.

With this information at his disposal, the shipbuilder is in a position to prepare his preliminary designs and to determine the most suitable dimensions. The settling of the most suitable dimensions is a task calling for considerable care, since the whole success of the ship will depend upon the solution of this problem. With given dimensions the weight of the ship's structure including hull, equipment and machinery can be calculated, and this weight together with the weight of the cargo to be carried (known as the *deadweight*) must not exceed the displacement of the ship at the required draught.

In addition, the depth of the vessel must be such that the distance from the water line to the deck must not be less than that given in the Tables of Freeboard. This distance, known as the *freeboard*, varies with the size of the ship and the nature and extent of the erections above the deck, and has been determined as the result of many years observations and experience. When dimensions giving a suitable deadweight and freeboard have been determined, the capacities of the various holds are calculated in order to ensure that there will be a sufficient volume to enable the cargo to be carried—for example, it will be clear that very different capacities will be required to house the same total weight of iron ore or of light piece goods.

If the ship is intended to carry passengers, regard must also be paid to the requirements as to the effective subdivision of the ship into watertight compartments, the object being to obtain a vessel which will remain afloat if 1, 2 or sometimes even 3 compartments are laid open to the sea by damage through collision or otherwise. The present official British regulations on this subject were formulated on the recommendations of a Committee appointed by the Board of Trade immediately after the sinking of the "Titanic" in April 1912 with the loss of some 1,500 passengers and crew. (*See* SHIPPING: *Registration, Classification and State Regulation.*)

The determination of a suitable breadth in relation to the depth calls for some care, since upon this depends the stability of the vessel, a vital factor, since the stability must be sufficient for safety but must not be so excessive as to cause the ship to roll uncomfortably in a seaway.

Finally, regard must be paid to the various official regulations of the countries between which the ship is intended to trade.

The designer will usually have, to guide him, the details of some successful ship or ships previously built to fulfil the same or similar conditions, and he will probably know what measure of success or popularity the respective features of such vessels have earned in service. The dimensions can in this event be readily fixed to provide the necessary speed and deadweight, stability and seaworthiness, and the cost of the vessel determined. On the other hand, if the departures from previous vessels or from the usual practice be very great, much will depend upon the designer's skill and judgment.

Outline drawings must first be prepared, based on dimensions which are considered suitable, and the various calculations made for this assumed design. These calculations will include the various factors to which reference has been made, and, if it is not intended to class the vessel with one of the recognized Classification Societies, questions of strength will have to be considered. If, however, the vessel is to be so classed, it may be assumed that the scantlings required by the Rules of such Society will provide generally sufficient strength. If the calculations show that the dimensions assumed do not enable the required conditions to be fulfilled, the dimensions must be modified and the calculations repeated, the process being continued until a satisfactory result is obtained. As soon as the dimensions selected for the vessel are found to be appropriate, more complete drawings are put in hand and the final calculations pertaining to the displacement, weights of hull and equipment, deadweight and capacity, centre of gravity and trim, while metacentric diagrams and curves of stability are also made.

FIG. 1.—MIDSHIP SECTION OF AN IRON SAILING VESSEL, ABOUT 1860
FIG. 2.—MIDSHIP SECTION OF AN IRON SCREW STEAMER, ABOUT 1860

In the case of the construction of large passenger vessels, complete drawings and specifications are prepared by the shipowners or by naval architects employed by them. In other cases, shipbuilders work in close connection with the shipowning companies and the business relations are of a very simple character, the shipowner being content to send a note of the principal dimensions, deadweight, capacity and type of ship required and to stipulate that the ship shall receive the highest class of one of the recognised Classification Societies, leaving the determination of the details of the design in the hands of the builders.

In any case complete design drawings and detailed specifications are necessary for the shipyard operations, and if not supplied must be prepared by the shipyard staff. The principal plans required are the sheerdraught and the profile and deck plans which show the general arrangement. The sheerdraught consists of an elevation showing the vessel's longitudinal contour, the position of the decks, the water line or line at which she will float, and certain other lines parallel to this and equally spaced below it, which are also called water lines, and of a series of vertical lines equally spaced from stem to stern called square stations; of a body plan showing the sectional form of the ship at the square stations—supposing her to be cut by transverse planes at these stations; and of a half breadth plan showing the form of the ship at the several water lines, supposing her to be cut by horizontal planes at the level of these lines. The profile and deck plans show all the internal arrangements of the vessel, the holds and spaces set apart for cargo, the position of the engines and boilers, the accommodation provided for the passengers and crew, and all the principal fittings throughout the ship. The midship section shows the structural arrangements of the vessel and the dimensions—or scantlings—of the more important parts of the structure. The specification is a statement of all the particulars of the vessel, including what is shown on the drawings as well as what cannot be shown on them. The quality of the materials to be used is carefully defined, and it is clearly stated how items not manufactured by the shipbuilders are to be obtained.

Practical Shipbuilding.—Practical shipbuilding requires a knowledge of the properties of materials used in the construction of ships, and also an acquaintance with the methods, means, and machinery by which, after delivery in the shipyard, the materials are brought to the required shapes, erected in their proper relative positions, connected together and completed so as to form a structure which shall fulfil the intentions of the design. The varieties of ships are very great and are constantly changing, and thus new problems are continually presented to the shipbuilder. There is also an ever increasing demand for rapid production which necessitates a constant search for simplification of methods of work, for labour-saving and time-saving machinery, for improved means of handling material in the shipyard, and for workshops which will more completely prepare and finish their products before dispatch to the shipyard.

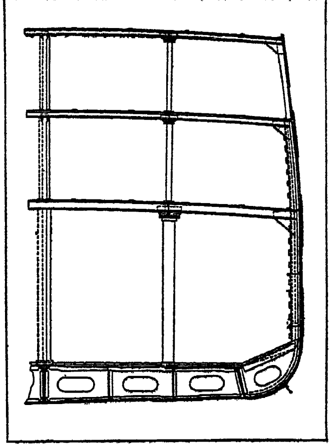
FIG. 3.—MIDSHIP SECTION OF A PASSENGER AND CARGO STEAMER, OF ABOUT 1860. FIG. 4.—MIDSHIP SECTION OF A TURRET DECK STEAMER, 1905

Whatever the size of the ship or the type to which she belongs, the general principles of construction remain very much the same in all cases. The exterior parts—the bottom, sides and decks—supply the strength required for the structure as a whole. The bottom and sides are spoken of as the *shell* or *outside plating* and are, with the decks, kept to the proper shape by means of frames running across the ship like the rafters in a roof or the ribs of a body. These are called *transverse frames* where attached to the shell or *beams* where they run under the decks. At the bottom of the ship where special strength must be provided to support the structure against grounding and in dry dock, the frames are considerably increased in depth and are known as *floors*. The tops of the floors are held upright in their correct relative positions by girders running lengthwise; one at the middle line being called the *centre keelson*, and others nearer the sides *side keelsons*.



BY COURTESY OF THE INSTITUTE OF NAVAL ARCHITECTS

FIG. 5.—MIDSHIP SECTION OF A CARGO STEAMER, ABOUT 1909

In all merchant vessels except those of small size an *inner bottom* is provided, the space between the inner and outer bottoms being utilised for carrying either water ballast or oil fuel. In such cases the centre keelson is called the *centre girder* and the side keelsons are called *side girders*. The centre girder is made continuous, and the deep transverse plates forming the floors extend from the centre girder to the ship's side. The side girders are fitted in pieces between the floors, and are said to be *intercostal*. Occasionally in large vessels one of the side girders is made continuous and the floors in that case are fitted *intercostally*. In modern vessels it is the practice to fit solid plate floors on every second or every third frame only, the remaining floors being built up of bulb angle bars inside the outer bottom and under the inner bottom with short bracket plates between them, the bracket plates being attached to the centre and other fore and after girders by short angle bars. Floors built up in this way are called *bracket floors*. Where, however, special local stresses have to be met, as in the machinery space or at the forward end of the ship, solid plate floors are fitted on every frame.

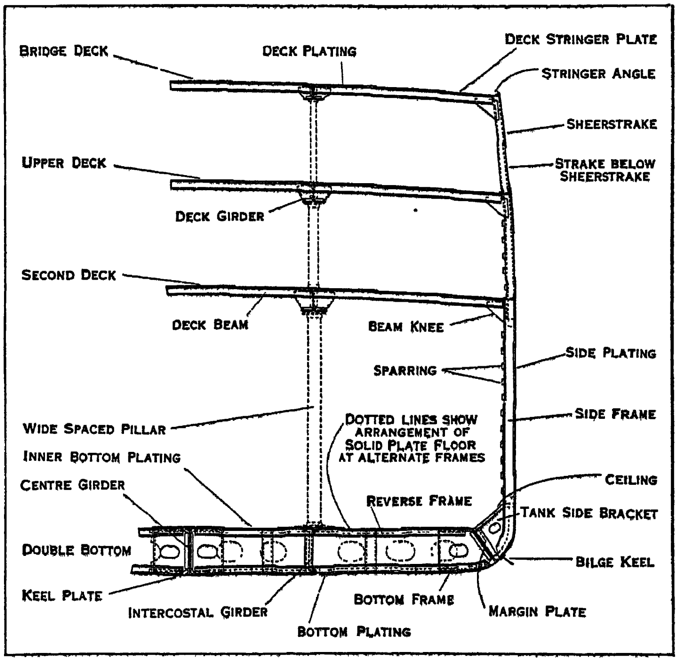


FIG. 6.—MIDSHIP SECTION OF A CARGO VESSEL, 1928

The inner bottom is generally stopped short at the side of the

ship and drops nearly vertically, thus forming a convenient pocket for drainage known as the *bilge,* the boundary plate of the double bottom being called the *margin plate.* The side frames outside the double bottom are attached to the margin plate by plate brackets called *tank margin brackets.*

Besides the ordinary framing, the transverse strength of the ship is much increased by the partitions fitted to divide up the internal spaces of the ship, which are called *bulkheads,* and which may be watertight or non-watertight as the circumstances of the case require. At the extreme ends of the ship the shell plating

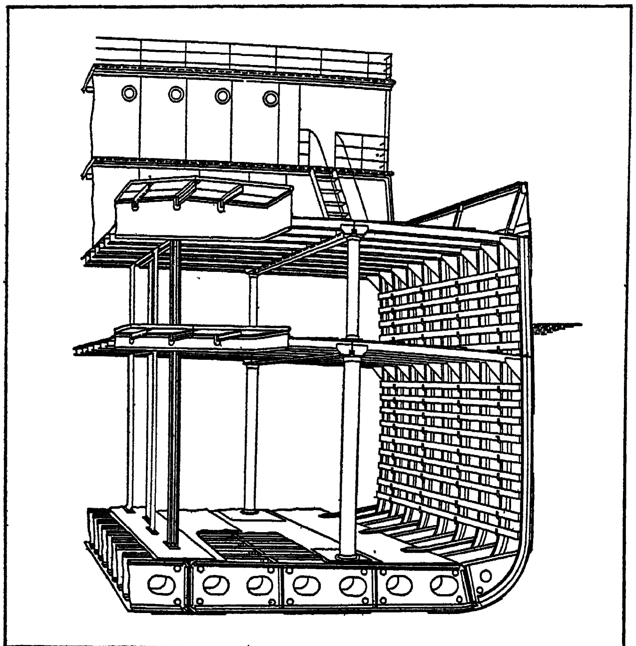

FIG. 7.—GENERAL PERSPECTIVE OF A CARGO VESSEL

on the two sides is attached to forgings or castings which are known as the *stem* at the fore end and the *sternframe* or *sternpost* at the after end. Towards the bow of the vessel particularly, additional supports are introduced to enable the ship to withstand the heavy blows of the sea in bad weather and are called *panting* stringers and *panting* beams, panting being the term applied to the movements which occur in the side plating if sufficient stiffness is not provided. At the stern a deep floor, called the *transom,* is attached to the upper part of the sternframe to form a base for the overhanging part of the stern which is known as the *counter.* To assist the beams in holding the decks in their correct position, vertical *pillars* are introduced in large numbers, but to avoid loss of space and inconvenience in handling cargo ordinary pillars are often dispensed with and a few strong pillars widely spaced with deep girders under the deck are fitted instead.

The general spacing of the frames varies from about 20 inches in small ships to 36 inches in large vessels; 36 inches is however common in ships of moderate size.

The whole tendency of modern shipbuilding is in the direction of simplifying the construction by redistributing the material, concentrating on the more important parts of the main structure, the remainder being treated largely on the basis of local considerations. The changes which have occurred over a period of years will be appreciated by a study of the construction of typical vessels from 1860 to 1928. (Figs. 1 to 7.)

The foregoing description may be regarded as covering mercantile vessels generally, with the exception of that large part of the mercantile marine devoted to the carriage of oil in bulk, a trade which has grown to such dimensions that in 1927 about 10% of the total world's tonnage consisted of oil-carrying vessels. These ships differ in many important particulars from ordinary cargo-carrying vessels. The oil carrying space, which usually extends for about half the total length of the ship, is divided by transverse bulkheads into tanks about 30 feet long. These tanks are subdivided bv a continuous *longitudinal centre line bulkhead* which extends from the keel to the weather deck. In order to provide for the expansion of the oil due to varying temperatures, an *expansion trunk* is provided usually by fitting a continuous fore and aft bulkhead between the upper deck and the deck below. The space between the expansion trunk and the ship's side is known as the *summer tank,* and is used as an additional space for oil cargo when light oils are carried. Vessels of this type are nearly

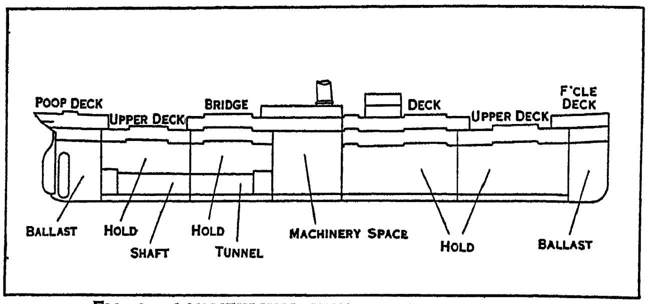

FIG. 8.—LONGITUDINAL SECTION OF A CARGO SHIP

all built on the *longitudinal system of framing.* In this system, designed by Sir Joseph Isherwood, instead of closely spaced transverse frames, deep frames formed of plates and angles known as *transverses* are fitted at intervals of about 10 feet. The shell and deck plating is supported by continuous longitudinal frames called *longitudinals,* which pass through slots in the transverses but are cut at the bulkheads, to which they are bracketed. The middle line and transverse bulkheads are stiffened in a similar manner, so that at each longitudinal there is a continuous horizontal girder right round the tank. The main features of this system will be clearly understood by reference to fig. 9, which shows the construction of a typical tanker.

The Isherwood system has also been applied to ordinary cargo vessels. The success which has attended this system has led to introduction of designs on which the framing at the bottom and deck is longitudinal, while ordinary vertical framing is retained at the ship's side. A number of ships have been built on this combination system and have proved satisfactory.

The most recent development in ship construction has been

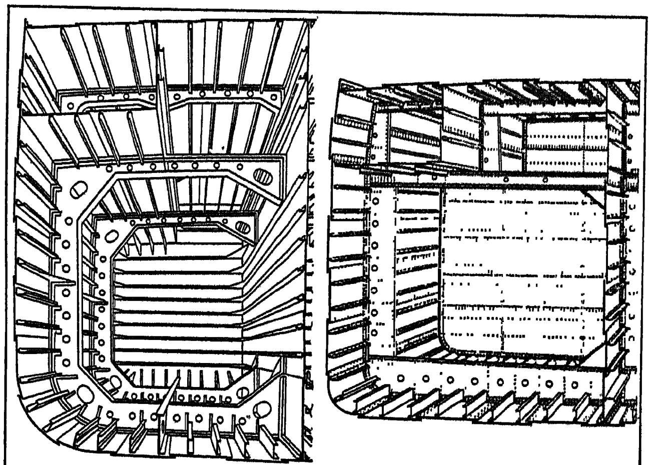

FIG. 9 FIG. 10

FIG. 9.—INTERNAL VIEW OF AN OIL TANK STEAMER BUILT ON THE ISHERWOOD PRINCIPLE. FIG. 10.—INTERNAL VIEW OF AN OIL TANK STEAMER BUILT ON THE BRACKETLESS SYSTEM

the introduction of the Isherwood *bracketless system,* which is a modification of the normal longitudinal framing in which the brackets attaching the longitudinals to the bulkheads are dispensed with. This has necessitated a rearrangement of the spacing of the transverses and the provision of special strengthening of the shell and deck plating in the neighbourhood of the bulkheads, and results in a great simplification of the structure and of the work of erection (see fig. 10).

Laying Off.—This is the name given to the process of drawing the lines of a ship to full size in plan and elevation in

order to determine the exact dimensions of the more important parts of the ship's structure, as the sizes of the various members must correspond with one another in order that, when assembled, there may be no irregularity or unfairness in the surface of the ship. The process is carried out on a specially planed and blackened wooden floor of such a size as to take in the full depth of the ship in its width. The room in which the floor is situated is called the *mould loft,* and is an important adjunct of the shipyard drawing office.

The principles of the methods of the projections of the various lines and planes are exactly to those followed in practical solid geometry, and do not call for any detailed explanation.

In different localities and in the construction of different types of ships, the extent to which the process of laying off to full size is employed varies considerably. In some yards laying off on a large scale on paper is relied on almost entirely, and very little full size work on the floor is considered necessary, particularly in the case of ships the lines of which have very little curvature over the greater part of their length.

The primary object in laying off a ship is to determine the exact shape of each of the frames, and these are drawn down on the *scrieve board,* which is an auxiliary mould loft floor constructed conveniently near the frame bending shop, which has copied on it all the information necessary for the correct shaping of the frames in the ship. All the frame lines are shown on the scrieve board, and the complete section of the frame surface for both sides of the ship is shown for each frame.

Special wood moulds are prepared giving the spacing of the rivet holes in the frames and floors, while wood battens are prepared on which are marked off the spacing of the rivet holes in the floors and keelsons.

Great progress has been made in recent years in the art of laying off, and wood moulds and battens can be prepared to suit the requirements of the different deck and shell plates, frames and beams so that it is possible to shape and punch the rivet holes in about 90% of the material before the vessel's keel is actually laid.

On account of the sharpness of form at the ends of the ship it is usual to make a wooden pattern of the exact shape of the plates at these parts from the structure after the frames have been erected, but in some instances even this has been unnecessary, and practically the whole of the material has been prepared in advance.

Materials.—Ships of the present day are almost invariably constructed of the material known as *mild steel,* which consists of iron with a small percentage of carbon, manganese, phosphorus and sulphur, a typical mild steel containing

	%
Carbon	·17
Manganese	·48
With not more than	
Phosphorus	·03
and Sulphur	·04

Mild steel is very tough and ductile, and differs from the hard steel out of which tools are made in that it will not take a *temper; i.e.,* if heated and plunged into oil or water the sudden cooling has very little effect upon it, whereas with tool steels a great change takes place—the steel becoming very hard and usually brittle. This quality of tempering depends chiefly on the amount of carbon in the steel, mild steel containing less than ·25%. Before being accepted for use in shipbuilding, steel is required to be submitted to a tensile and to a bend test. For the purpose of the tensile test, strips are cut from the plates or bars and are machined to give a parallel part about 2 inches in width of at least 8 inches in length. Two marks are made, 8 inches apart, and the strip is secured in a testing machine constructed so that the ends of the strip can be gripped by strong jaws beyond the parallel parts. The jaws are then gradually pulled apart, the amount of the pull required to break the strip being registered, and also the extent to which the strip stretches in the length of 8 inches before breaking. The tensile strength varies between 26 and 32 tons per square inch calculated on the original sectional area of the parallel part before breaking, and the elongation in the 8 inches is not less than about 20%. In addition to the tensile test, sample strips 2 inches in width are cut and are bent double by hammering or in a press until the bend is a semi-circle the diameter of which is 1½ times the thickness of the plate. As an additional test the strips are sometimes heated and plunged into water to cool them suddenly before bending.

The steel used for making rivets is similarly tested, and samples of the finished rivets are also taken and are hammered into various shapes (some hot and some cold) to ensure that the metal is soft and ductile and suitable for the work.

The testing of ship steel is practically always carried out under the supervision of one of the Classification Societies, and their principal requirements in this respect may be tabulated as follows:—

Ship steel	Lloyd's register	British corporation	Bureau veritas	Germanischer Lloyd
Plates	26–32	28–32	27–32	26–31
Bars	26–32	28–33	27–32	26–31
Rivets	25–30	25–30	24–29	21·5–30

(*Figures given represent stress in tons per sq. in.*)

The testing is carried out at the steel works, and if the material is passed each plate and bar is stamped with the brand of the Classification Society and with an identification mark which would enable it to be traced back to its origin should it prove unsatisfactory in course of being worked in the shipyard.

The stem and sternframe are generally made of forged iron, but are also made of cast steel. Castings are tested by being let fall on hard ground and are then slung in chains and hammered all over, flaws being detected by the sound produced. To test the quality of the steel in the casting, small pieces which are cast on for the purpose are removed and tested in the same manner as the samples cut from the plates and bars; these test pieces should have about the same tensile strength as those cut from plates, but a little less ductility may be permitted.

The last few years have witnessed the introduction of a new type of material known as *Special Quality Steel,* which possesses elastic properties superior to ordinary mild steel. This material can withstand a stress of about 15 tons per sq. in. without suffering any permanent deformation, as compared with a much lower figure—say 7 or 8 tons per sq. in. for mild steel. The superior properties of the new material are obtained chiefly by exercising great care to see that in the course of manufacture the temperature of the steel does not fall below a given critical temperature before the operation of rolling is completed. On account of its superior properties certain reductions in scantlings are allowed, which result in a saving of weight of steel in a moderate sized vessel of about 10%. Several ships have been constructed of this material, and have proved quite satisfactory, although the experience available does not yet permit of any definite conclusions.

The sections of the steel bars in common use are named as follows:

A Angle	*D* H-bar	*G* Half round
B Tee	*E* Bulb Plate	*H* Cope Iron
C Channel	*F* Bulb Angle	

The vertical portion of the *H, T,* channel and bulb sections is called the *web* and varies from about 3 inches to 12 or even 17 inches in depth; the horizontal parts are called the *flanges,* this term being applied to both branches of an angle. The flanges of channels and bulb angles vary from 2½ inches to 4 inches in breadth and in an angle bar from 2½ inches to 8 inches. The thickness varies from ¼ inch to ¾ inch. These dimensions taken together are known as the scantlings of the material. The thicknesses of the plates in common use generally lie between ¼ inch and 1 inch. Thinner or thicker plates or bars are obtainable, but are not often used. Plates are of varying sizes as required but in general vary from about 4 feet to 8 feet in breadth and from 20 to 30 feet in length, the actual size used depending upon the dimensions of the ship and the facilities for working in the shipyard. Bars are supplied in lengths of from 20 to 80 feet as re-

quired or as may be limited by the means of transport between the steel works and the shipyard. The various plates and bars in a ship are connected together by *rivets*. Types of rivets are distinguished by the names of the heads and points as follows:

A. Countersunk head
B. Snap head
C. Pan head
D. Pan head with conical or swelled neck
E. Countersunk point
F. Rough hammered point
G. Snap point hand work
H. Snap point machine work

The pan head rivet with swelled neck (*D*) is the most commonly used, as it is convenient to handle and gives sound work. The snap head (*B*) and the pan head (*C*), without cones under the heads, are used only for small work, while the countersunk head is only employed where a flush surface is desired. The countersunk point (*E*) is used on the outside of the shell and other places where a flush surface is required; elsewhere the rivet is finished off with a rough hammered point (*F*). Where riveting is done by hydraulic machinery, rivets having snap heads (*B*) and snap points (*H*) are used. Rivets vary in diameter from about $\frac{5}{8}$ inch to $1\frac{1}{4}$ inch, depending on the thickness of the plates to be connected, the diameter being usually about $\frac{1}{4}$ inch more than the thickness of the separate plates. The lengths of the rivets are as required to go through the total thicknesses of the plates and leave enough material properly to form the points. The distance from centre to centre of the rivets is spoken of as the pitch, and is usually expressed in diameters. For connecting plating to framing or beams the pitch is usually 7 diameters; for securing edges which must be watertight, the pitch is from $4\frac{1}{2}$ to 5, or if the edges are to be oiltight $3\frac{1}{2}$ diameters. In the butts and edges of shell plating the pitch varies from $3\frac{1}{2}$ to $4\frac{1}{2}$ diameters. In some positions rivets like the above cannot be drawn into place and properly hammered up; resort is then made to rivets which have screwed points, called *tap rivets*. The rivet is screwed up by means of the square head which is chipped off after the rivet is hove up tight.

Course of Construction.—On the receipt at the shipyard of the design drawings and specifications, steps are taken to put in hand the detailed drawings of the structural arrangements which will enable materials for the various parts to be ordered from the manufacturers and will provide information for the guidance of the workmen in the erection of the structure.

A wooden model of half the exterior surface of the ship, called the *half-block* model, is immediately prepared from the sheer drawing, generally to a scale of $\frac{1}{4}$ inch to the foot. On its surface are carefully drawn the main frames, the edges and butts of the shell plating, the positions of the decks, and other features which will influence the detailed arrangement of the framing and plating. The work on this model is carried out concurrently with the laying-off of the ship so as to be complete by the time the latter is sufficiently far advanced to enable full size measurements of the breadth of the plates to be obtained. The lengths of the plates are then measured from the model and the breadths from the mould loft floor (a small surplus on the net measurements being allowed to provide for inaccuracies), and the whole of the shell plating is ordered from the steel works.

For flat or nearly flat surfaces such as keel plate, bulkheads and decks, the detailed arrangements are made on drawings from which the dimensions are taken for ordering the material while the drawings themselves constitute working plans which are issued for general guidance in building the ship. In addition to these principal structural drawings a very large number of detailed plans showing the arrangement of passenger and crew accommodation, systems of piping and ventilation and numerous other details are necessary. Very much of the success achieved in actual building will depend upon the efficiency of the drawing office, which must supply accurate and detailed working plans, which must be ready as soon as required. Each firm has its own system of work in these departments but experience shows that the more thorough and systematic the work in the drawing office and its adjunct, the mould loft, the better the general result.

A very important record kept during the building of the ship is the cost of materials and labour, a very careful account being kept of the workmen's time whether employed on piece or by the day. Many different systems are in vogue but the aim in all cases is to record the cost of the labour in each trade and the detailed cost of the various parts of the ship.

The first stage in the actual erection of the vessel is the laying of the keel blocks, a task undertaken by the shipwrights assisted by labourers. The blocks consist of several pieces of rough, rectangular timber about 12 inches square and 4 to 6 feet in length, laid on top of each other to the height required. The top block is called the cap piece and is of oak. The spacing of the blocks depends to some extent on the size of the ship, but is usually about 4 feet. It is essential that the ground under the keel blocks should be firm and hard, otherwise the blocks may sink when weight becomes concentrated on them during building and the keel may consequently droop from a straight line. The upper surface of the blocks must be at such a height from the ground that men, especially riveters, can do their work with facility under the bottom of the vessel and that when launched the vessel may move down into the water without striking the ground. The last named is a very important consideration, and thus it happens that the first thing to be settled before the blocks are laid is how the vessel is to be launched. The tops of the blocks are securely adjusted to a slope of about $\frac{5}{8}$ inch per foot run from bow to stern. The shipwrights at the same time prepare the uprights for the staging and erect them in suitable positions round the building berth. The platers begin to prepare the keel, framing and bulkheads as soon as the material is delivered and the laying off and mould making are sufficiently advanced for the purpose.

Details of Structure: *Keels.*—The keels of small vessels usually consist of a stout flat bar placed vertically and attached to the garboard strakes by through rivets. In larger ships the keel usually consists of a wide horizontal plate running along the centre line of the bottom, the sides being turned up as necessary to follow the shape of the bottom.

Framing.—The framing varies considerably with the size and type of the ship. In small vessels a frame usually consists of an angle bar, called a *frame bar*, extending from the centre line to the gunwale. To the frame bar is riveted another angle called a *reversed bar*, in such a way as to form a built up Z bar, while at the bottom the frame and reversed frame are separated in order that both may be attached to the *floor plates* which form deep girders across the bottom to give the required strength when the vessel is resting either on the ground or on the keel blocks. The usual procedure in constructing a complete frame and floor is as follows: From the scrieve board the shape of the section of the frame is transferred to the bending slabs, the outline being drawn in with chalk; the frame bar is drawn from the furnace and while hot is bent to the required shape and given the necessary bevel. The reversed bar is prepared in the same way except that the inner edge of the frame and floor must be worked to. The floor plate requires to be cut to shape. The frame, reversed frame and floor all being prepared, are placed together in their respective positions over the outline of the frame on the scrieve board, the final adjustments made, and rivet holes marked and punched and the work secured and riveted up. In many instances the frame is formed of a bulb angle, in which case the reversed bar is fitted only on the upper edge of the floor plate and does not extend up the ship's side. In vessels fitted with double bottoms the frame bar extends from the tank side margin plate to the gunwale but the general process of marking and bending proceeds as described above.

Double Bottoms.—There are a considerable number of variations used in the construction and arrangement of double bottoms. At the centre line immediately over the flat keel plates there is a vertical girder the full depth of the double bottom, connected to the flat keel plate and to the centre plate of the inner bottom by continuous double angle bars. This centre girder may or may not be watertight, according to the desired tank arrangements.

The floor plates, which extend from the centre girder to the margin plate, are provided on their edges with angle bars for attaching them to the outer and inner bottoms, to the centre girder and to the margin plate. As will be seen, the margin plate cuts completely through the transverse frames, and special brackets are fitted to maintain the transverse strength. The chief advantages derived from cutting the frames at the margin plate are the ease with which watertight work is secured and the rapidity with which this part of the structure can be proceeded with. Except where it is desired that the floors should be watertight, manholes are punched for the purpose of providing ready access to all parts of the bottom. Between the centre girder and the margin plate one or more intercostal girders are fitted, these girders consisting of plates fitted in short lengths between the floors, to which and to the inner and outer bottoms they are attached by short pieces of angle bar.

With a view to rendering the bottom more easily accessible it is now customary to fit plate floors at every second or third frame only, the intermediate floors being built up of angles or bulb angles connected together by plate brackets. Such floors are known as bracket floors. Solid floors must be fitted on every frame under the machinery and at the forward end of the ship.

Decks.—The decks are very important parts of the structure from the point of view of both transverse and longitudinal strength, but their number and position necessarily vary considerably with the size and type of the vessel. In bulk cargo ships the number of decks is reduced to a minimum, and some ships having a depth of about 32 ft. have been built with one deck only, while in a similar passenger ship there might be three decks.

Decks are supported primarily by the *deck beams,* which are usually formed of bulb angles and are attached to the side frames by a number of plate knees. The beams may be fitted either to every frame or to alternate frames, and are in turn supported by *deck girders,* the latter being carried by pillars which may be closely spaced, say at every second frame, or may be spaced as much as 30 feet apart. The decks are generally completely plated over, the thickness of the plating being greatest on the top deck, and each deck being less in thickness than the one above. Thus in a ship with three decks the top deck might be ·50 inch in thickness and the two lower decks ·40 inch and ·30 inch respectively. The strake of deck plating next the ship's side is called the *stringer plate* and is attached to the shell plating by an angle bar known as the *stringer angle.* In passenger ships it is customary to sheathe the steel decks with wood, usually pitch pine 2½ inches in thickness, where exposed to the weather, and to lay a composition of which the principal ingredient is sawdust about 1½ inches thick inside the passenger accommodation. In cargo ships the steel deck is left bare except in the crew's accommodation.

Shell or Outside Plating.—The outside or shell plating forms the watertight skin of the ship and also contributes the major part of the structural strength. The plating is arranged lengthwise in a series of *strakes* about 60 inches in breadth, the overlaps of adjacent strakes being called *seams.* The plates are usually about 30 ft. in length and adjoining plates in the same strake are overlapped, these joints being known to shipworkers as *butts.* Thickness of the plating is governed by the necessity for providing sufficient structural strength, and this thickness is usually maintained for half the vessel's length, from whence it is tapered off to the ends where the thickness is about two-thirds of the midship thickness. The mould loft supplies templates and battens for the different plates in each strake, and it is not uncommon for a very large part of the shell plating to be shaped and punched before the framing is erected.

Watertight Bulkheads.—In regard to the general arrangement and method of stiffening a watertight bulkhead, bulkheads are assembled on some convenient flat surface and the rivet holes marked in the plating and stiffeners, after which they are transferred piece by piece and erected in their proper positions in the ship.

Erection.—The system and order of erection of the vessel varies in different districts, but the following general description may be considered as typical. After the keel blocks have been erected and faired, the flat plate keel is placed in position and the centre girder erected. The floors in the double bottom are then erected and the tank margin plate, the inner bottom plating and the outer bottom plating are attached to the floors. The side frames are then hoisted into position, and the deck beams, deck plating and side shell plating erected. The various parts of the ships are temporarily secured by bolts, great care in the meantime being taken to see that the correct form of the vessel is maintained.

As each part of the work is completed by the platers it is ready for the riveters and caulkers, and these trades follow on without delay. Platers usually work in squads composed of three or four platers, a marker boy and a number of labourers or helpers, the number depending on the size or weight of the plates and also on the facilities of the yard for handling such material. On the work of a large vessel many such squads may be employed. The riveters also work in squads, a squad consisting of two riveters, a holder-on (whose duty it is to hold a large hammer against the head of the rivet while the point is being hammered down on the opposite side of the plate by the riveters), and a heater boy. Hand riveting is being largely supplanted by riveting executed by pneumatic hammers, while for those parts which can be riveted before being erected in position hydraulic riveting is employed. After the riveting is completed all watertight work is caulked, this process consisting of forming a shallow ridge along the edge of the plate to force this edge into close contact with the surface of the adjacent plate. A very important part of a caulker's work is testing the various watertight double bottom compartments or oil bunkers by filling them with water. A pressure is applied by means of a stand pipe carried to an appreciable height above the surface of the tank.

When the work on the hull is completed, the vessel is ready to be launched after being painted. It is usual to defer painting as long as possible so that the black mill scale on the plating may be exposed to the atmosphere and thus more readily removed. Red and white lead, oxide of iron and oxide of zinc form the basis of most of the paints used on steel ships.

Vessels Carrying Oil in Bulk.—The vast expansion in the use of oil as a motive power in all branches of engineering has led to a corresponding increase in the amount of tonnage devoted to the transport of oil in bulk, and at the present time oil-carrying vessels form some 10% of the tonnage of the mercantile marine. In the early stages of the industry the oil was transported in barrels or in special tanks fitted in the holds, but this system was found to be very uneconomical and vessels were accordingly designed to carry the oil in bulk, the first ship of this kind being the "Gluckauf," built in 1886.

The design of oil-carrying ships has passed through various phases, but for a considerable number of years past the great majority have been constructed on the longitudinal system of framing, more generally known as the Isherwood system. The oil is carried in tanks which form the structure of the ship, the boundaries of the tanks being formed by the skin of the ship, by transverse bulkheads spaced about 30 feet apart and by a middle line fore and aft bulkhead, which extends from the keel plate to the top deck. The second deck extends inwards from the ship's side for about one-quarter the breadth of the vessel and is united to the upper deck by a continuous longitudinal bulkhead, the space between this bulkhead and the middle line bulkhead being known as the expansion trunk, which permits of the expansion of the oil due to variations in temperature and also restricts the amount of movement of the oil when the ship rolls. The spaces between the expansion trunk and the ship's side, called summer tanks, are also used for cargo when oil of light density is carried. The form of the vessel between the transverse bulkheads is maintained by a continuous deep girder right round the ship called a transverse, the transverses being usually spaced about 10 feet apart. The shell and deck plating is supported by channels and bulb angles called longitudinals, spaced about 30 inches apart and extending continuously between the transverse bulkheads, to which they are attached by plate brackets. The middle line and transverse bulkheads are stiffened in a similar

manner by strong vertical webs in association with bulb angle horizontal stiffeners. Several hundred vessels have been built on this system and have proved very successful, the only trouble experienced having been in the rivets attaching the longitudinals to the bulkheads. To overcome this difficulty a new design, known as the bracketless system, has recently been introduced. The outstanding feature of this system is the entire elimination of the brackets attaching the longitudinals to the bulkheads, the discontinuity at the transverse bulkheads being compensated for by the fitting of local doublings on the shell plating.

Motorships.—A revolutionary change in the mercantile marine was foreshadowed by the appearance in 1910 of the first ocean-going vessel to be driven by internal combustion engines. Progress in this direction was naturally retarded by the World War, and it was only about 1921 that the construction of motorships was commenced on a large scale. Since then the development has been very rapid, and at the present time about 50% of new ships are of this type.

Viewed from an economic standpoint, a comparison between motor-engined and steam driven vessels, the ship being the same in each case, indicates that—

(a) there is an increased first cost;

(b) the wage cost per ship tends to be less, while the cost of handling oil on the ship is much below that required for coal;

(c) there is a greatly reduced consumption of fuel—which fuel, though costly, yet costs less in the aggregate than coal.

(d) there is an increase in the deadweight available for cargo, due principally to the reduction in the weight of the fuel carried;

(e) there is also an increase in the capacity of the space available for cargo.

The actual differences must necessarily vary with the size and type of ship, but for a steamer carrying about 8,000 tons deadweight the coal consumption per day would probably be about 30 tons, whereas for a motorship oil would only be consumed at the rate of about 8 tons. Allowing an average weight of coal of 1,000 tons, which has to be deducted from the available deadweight of 8,000 tons, the coal-burning ship can only carry 7,000 tons, whereas the motorship carries about 7,750 tons, or about 10% more. The increase in the space available for cargo would amount to about the same percentage.

In the early days of motorships trouble was necessarily experienced from mechanical defects in the machinery, due primarily to the high temperature of combustion of the gases in the engine cylinders. Much patient research work has overcome these troubles, and the fact that many of the largest modern liners have been fitted with motor machinery, and perform their voyages to schedule without any question of breakdown, indicates that the motorship now occupies an established position and that these ships will in all probability form an increasing percentage of the world's tonnage.

Launching.—When the steel work of the hull has been practically completed the vessel is ready for launching. It will be appreciated that the operation of transferring to the water a ship whose weight in the case of the largest vessels might amount to as much as 17,000 tons requires considerable forethought and is not unattended with some risk. The launching ways are erected at about one-third of the breadth of the ship on each side and consist of two sets of ways, the fixed or ground ways and the sliding ways. The fixed ways commence near the bow and extend for the full length of the ship, being carried out as near low water mark as possible in order to ensure that there shall be ample depth of water—say from 3 to 6 feet—over the ends of the ways, to ensure a successful launch. These fixed ways consist of solid baulks of timber varying from 15 to 60 inches in breadth, according to the size of the ship to be launched, and are laid on closely-spaced supporting blocks. The sliding ways, known as the cradle, are laid on top of the ground ways, the space between the ways and the hull being filled up with timber neatly fitted to the vessel's shell plating. The ways are laid with an inclination of about ⅝ inch per foot in order that the ship may slide easily into the water. Two or three days before the launch, the cradle which has been fitted in place temporarily is taken adrift and the surfaces of both the fixed and sliding ways are thickly covered with melted tallow; when this has hardened it is smeared with soft soap, after which the sliding ways and the various making up pieces of the cradle are replaced. Until the moment of launching, the sliding ways are locked to the ground ways by means of a dagger, one either side at the forward end. To launch the vessel the two daggers are released simultaneously, and the vessel usually commences to move of its own accord. When launched in open water the vessel is brought up when clear of the ways by dropping an anchor. When launched in a narrow river the vessel must be stopped quickly before the stern strikes the opposite bank, and this is done by leading strong steel wires from the bow and attaching them to heavy piles of chain, the friction of the chain as it is dragged over the ground gradually bringing the vessel to rest. (W. S. A.)

SHIPBUILDING: WORLD'S STATISTICS. The shipbuilding of the world during the last generation has undergone considerable changes. Statistics are not available in detail for more than some 30 years, dating back to the time when steam was definitely replacing sail. About 1880 there was as much sailing ship tonnage in existence as steam, but by the beginning of the present century the sailing ships were less than a quarter of the world's total tonnage, and to-day they are a very rapidly decreasing quantity, being only about 3%.

Tonnage statistics are generally given in gross tons, and for vessels which are of 100 gross tons and upwards. There are of course a large number of smaller vessels mainly engaged in the coasting trades which are below that size. Table I. gives the annual shipbuilding output of the principal maritime countries since 1894, and Table II. gives the amount of motor ships built since the war.

The motor ship began its practical existence in 1911, and in 1919 there were about ¾ of a million tons in existence, whereas in 1928 the figure was probably about 4½ million tons. It will be

The figures given (all from Lloyd's Register Book) are in 1000's of gross tons (000's omitted), and exclude vessels built on the Great Lakes. The particulars for Germany where shown blank were not available. The shipbuilding output for Italy now includes Trieste.

TABLE II. *The Gross Tonnage of Motor Ships (Included in Table I.) which was Launched in the Years Shown*

Year	World	U.K.	U.S.A.	Germany	France	Holland	Japan	Italy
1920	170	87	20	..	..	18	..	6
1921	293	102	32	33	..	14	..	14
1922	202	78	2	47	..	5	1	10
1923	222	87	13	47	9	6	1	7
1924	499	237	21	96	..	15	16	27
1925	842	267	24	279	24	32	16	101
1926	702	202	16	70	34	55	28	153
1927	864	356	39	116	17	86	18	50
1928	1180	428	25	177	55	85	59	36

seen from Table II. that although the motor ship is comparatively a recent introduction, the production, which was 170,000 gross tons in 1920 was no less than 862,000 in 1927.

Motor ships are now being built by all the principal maritime countries, more particularly by Germany and Italy, Germany having launched more than the United Kingdom in 1925, and Italy having built 75% of that built in the United Kingdom in 1926. In 1927, however, the United Kingdom had about its proportionate share of motor shipbuilding. Although not included in the table, mention must be made of the specialization in Sweden and Denmark of the building of motor ships, Denmark having launched 64,000 tons, and Sweden 62,000 tons in 1927.

Table I. which gives the total shipbuilding, shows a very great fluctuation in the tonnage launched from year to year. For example, the tonnage launched in 1897 was 1,277,000, whereas that launched in 1901 was 2,441,000. If another period be taken, the output in 1909 was 1,472,000, whereas the amount in 1913 was 3,263,000. The same kind of variation is observable with the United Kingdom, where the tonnage output for 1908 was 930,000, whereas that in 1913 was 1,932,000.

It would thus appear that there is a great fluctuation in the demand for new ships, and it may roughly be stated that the maximum production of new ships is about twice the minimum production. It also appears that this variation from the maximum to the minimum and back again occurs more or less regularly every 6–7 years.

The war period 1914–18 was, of course, very abnormal, and the statistics show that the special endeavours made to build merchant ships during the war were continued until about 1920–21, particularly in the United States. It will also be seen that, as a result of the war, the shipbuilding facilities of the world were doubled, whereas the actual demand for new ships in the world after the war period had not in 1928 reached pre-war requirements.

The United Kingdom is the greatest shipbuilding country in the world. Whereas in 1894 the great majority of ships were built in the United Kingdom, yet other countries, particularly Germany, rapidly developed. For the 9 years 1905–13, the United Kingdom built nearly two-thirds of the world's ships. In the 6 years ending 1927, which may very fairly be taken as the post-war period, the share of Great Britain had fallen to approximately 50%. This is due to the greater development of motor shipbuilding on the continent of Europe, and to high costs. (W. S. A.)

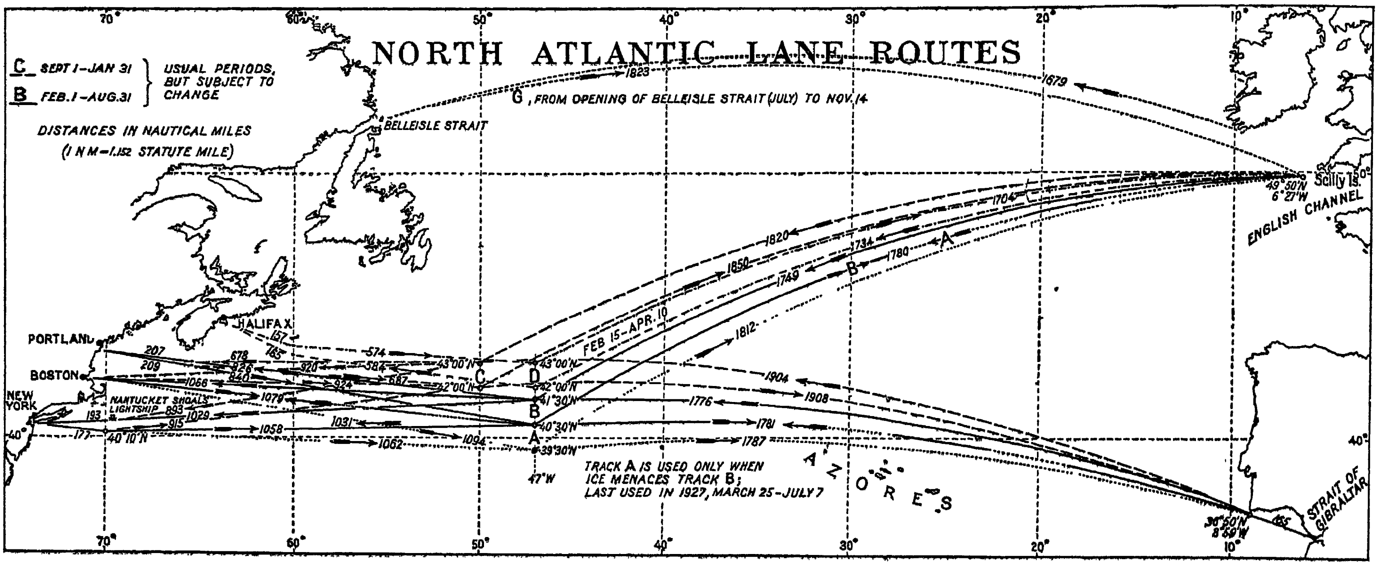
SHIPKA PASS, in Bulgaria, a pass in the Balkans, celebrated as the scene of fierce fighting in the Russo-Turkish War of 1877–78. The main road from Rumelia to Bulgaria, leading from Sistova by Tirnova and Eski Zagra to Adrianople, crosses the Balkans near the village of Shipka, and this passage was of necessity an important point in the Russian plan of operations. The road does not pass between high peaks, but crosses the main ridge at the highest point; it is therefore not a pass in the ordinary sense of the word. Near the summit, running parallel, and close to the road is a series of three ridges, some 200 ft. high, and about 2 m. from north to south, which formed the position for a force holding the pass. It was originally held by a Turkish force of about 4,000 men with 12 guns, prepared to resist the Russian advance. On July 17 they repelled a feeble attack from the north, and the following day faced round and drove back an attack by Gourko from the south. These attacks were to have been simultaneous, but Gourko, having met with unexpected resistance, was a day late. Though so far successful, the Turks evacuated their strong position, and it was occupied by the Russians on July 19.

Suleiman Pasha, having concentrated with Reouf Pasha and driven Gourko across the Balkans at the end of July, moved to the Shipka on Aug. 21 and attacked. The Russian force there, including five battalions of Bulgarians, then numbered 5,000, but that day a regiment from Selvi brought their numbers to 7,500, and this force held the position against 30,000 Turks for three days, when heavy reinforcements arrived. The fighting continued till the morning of the 26th, when Suleiman, his troops being exhausted, and having lost 10,000 men, entrenched himself in the position he then occupied in a semi-circle round the southern end of the Russian position. Having called up more battalions from Yeni Zagra, after a four days' artillery bombardment, he attacked on September 17 and was repelled with a loss of approximately 3,000 men.

There was no more fighting on the Shipka till the general advance of the Russians after the fall of Plevna. Radetzky's command of about 60,000 men advanced from Gabrova on Jan. 5, in three columns. Radetzky, with the central column, moved by the main road and attacked the Turks, who still faced the position on the summit, while Skobelev and Mirski, crossing by trails some 3 m. to the west and east of the Turkish position, attacked their reserves on the far side, about Shipka and Shenova, where Vessil Pasha (who had succeeded Suleiman in command) had formed an entrenched camp. These flank columns made their way over the mountains, deep in snow. Mirski attacked alone on Jan. 8, as Skobelev's advance had been delayed, but the following day both columns attacked, and after fierce fighting the Turks surrendered. The force on the summit had that day repulsed, with heavy loss, a frontal attack by Radetzky, but they were included in the surrender. Their numbers were 36,000, including 6,000 sick and wounded, and 93 guns. The Russian losses were 5,500.

Not only were the Turkish attacks on the Shipka unsuccessful, but they were made without object. At the end of July, when Suleiman forced Gourko back over the Balkans, the moral equilibrium and the plan of operations of the Russians had been upset by the second battle of Plevna, and the Shipka ceased to have any strategical importance for the time being. Had Suleiman at that time followed up Gourko and joined Mehemet Ali, or moving round acted with Osman against the Russian flank, the evacuation of the Shipka would have been compulsory. Suleiman, knowing nothing of strategy, preferred to act independently, and his action was supported by the still more ignorant ministers at Constantinople. The Shipka was merely a geographical point until the Russians were prepared to advance, but, fortunately for them, the Turks chose to waste an army in fighting for it throughout the critical period of the operations. Suleiman divided his forces and used up his troops in costly frontal attacks on Mt. St. Nicholas, the southern and strongest point of the position, whereas a well-supported flank attack would probably have met with success. The manner in which he sacrificed his men earned for him the name of the "Shipka butcher." (J. H. V. C.)

SHIP LANES OF THE NORTH ATLANTIC. The sinking of the U.S. mail steamer "Arctic" in October 1854, by collision with the French steamer "Vesta," in a thick fog while on passage from Liverpool to New York, resulted in a loss of about 300 lives. This disaster inspired Lieutenant M. F. Maury, U.S. Navy, then superintendent of the "Depot and Observatory," Navy Department, to include in his *Sailing Directions* published in 1855 a section on "Steam Lanes Across the Atlantic." Therein he graphically depicted and recommended the establishment of a lane or strip of ocean for the steamers to go out and another for them to come in so that not only would the liability to danger from collision between steamers, as well as between steamers and sailing vessels, be lessened, but a new resource upon the high seas would, in many cases of wreck and disaster, be afforded to those in distress. The lane to Europe crossed the 50th meridian of west longitude in latitude 42°, and was from 15 to 20 m. wide; the lane from Europe crossed the 50th meridian of west longitude 200 m. to the northward and was from 20 to 25 m. wide, the lat-



ter being made wider on account of the large percentage of fogs, the greatest width in both lanes being given where most fog was expected.

The U.S. Hydrographic Office, Navy Department, established in June 1866, first called attention in 1872 to the necessity of lanes across the North Atlantic ocean between U.S. ports and the region south of Ireland and England. This was followed by successive endeavours principally presented to the maritime world through the monthly *Pilot Chart of the North Atlantic Ocean.* One of these charts, issued in Dec. 1887, carried in addition to amended Maury's lanes the admonition that the dangers most in mind were fog, ice and the fishing fleet off the Grand Banks, and the Hydrographic Office strongly recommended for adoption the lanes shown.

The International Marine Conference, held in Washington in 1889, attended by delegates from 26 maritime countries, provided: "Steamer lanes for trans-Atlantic navigation are not adopted, although the various steamship companies are urged to adopt regular routes for vessels of their own line." In 1891 at a conference between representatives of five of the principal trans-Atlantic steamship companies, the Cunard, White Star, Inman, National and Guion lines, certain routes were formally adopted, to be followed by all vessels of those lines.

The adoption of these safe and well-defined routes between Sandy Hook (and Boston) and the Fastnet could but be regarded as most important in its bearing upon the safety of navigation in the North Atlantic ocean, and especially gratifying to the Hydrographic Office, as the most essential features of the tracks were exactly what had been recommended on the pilot charts for years.

At the International Convention for Safety of Life at Sea, London, 1913–14, at which representatives of 14 maritime nations were represented, convened subsequent to the "Titanic" disaster, the following was adopted: "The selection of the routes across the North Atlantic in both directions is left to the responsibility of the steamship companies, nevertheless the High Contracting Parties undertake to impose on these companies the obligation to give public notice of the regular routes which they propose their vessels should follow, and of any changes which they make in them. The High Contracting Parties undertake, further, to use their influence to induce owners of all vessels crossing the Atlantic to follow as far as possible the routes adopted by the principal companies."

With but minor changes the routes used by the principal steamship companies before the London convention were continued to be used until 1924, when the companies working for a North Atlantic track agreement adopted with but minor changes the North Atlantic lane routes A, B, C, D and G, are shown on the accompanying chart, which routes are seasonal and provide for safety from danger of ice, fog and collision with fishing vessels on the Grand Banks. (C. S. K.)

SHIP-MONEY, a tax, the levy of which by Charles I. of England without the consent of parliament was one of the causes of the Great Rebellion. The Plantagenet Kings of England had exercised the right of requiring the maritime towns and counties to furnish ships in time of war; and the liability was sometimes commuted for a money payment. Notwithstanding that several statutes of Edward I. and Edward III. had made it illegal for the crown to exact any taxes without the consent of parliament, the prerogative of levying ship-money in time of war had never fallen wholly into abeyance, and in 1619 James I. aroused no popular opposition by levying £40,000 of ship-money on London and £8,550 on other seaport towns. On Feb. 11 1628, Charles I. issued writs requiring £173,000 for the provision of a fleet to secure the country against French invasion and for the protection of commerce, and every county in England was assessed for payment. This was the first occasion when the demand for ship-money aroused serious opposition. Lord Northampton, lord-lieutenant of Warwickshire, and the Earl of Banbury in Berkshire, refused to assist in collecting the money; and Charles withdrew the writs.

A further writ was issued in Oct. 1634 and directed to the justices of London and other seaports, requiring them to provide a certain number of ships of war of a prescribed tonnage and equipment, or their equivalent in money, and empowering them to assess the inhabitants for payment of the tax according to their substance. The distinctive feature of the writ of 1634 was that it was issued, contrary to all precedent, in time of peace. The citizens of London immediately claimed exemption under their charter, while other towns, demurred to the amount of their assessment; but no resistance on constitutional grounds appears to have been offered to the validity of the writ, and a sum of £104,000 was collected. On Aug. 4 1635, a second writ of ship-money was issued, directed on this occasion, as in the revoked writ of 1628, to the sheriffs and justices of inland as well as of maritime counties and towns, demanding the sum of £208,000, which was to be obtained by assessment on personal as well as real property, payment to be enforced by distress. This demand excited growing popular discontent, which now began to see in it a determination on the part of the king to dispense altogether with parliamentary government. Charles, therefore, obtained a written opinion, signed by ten out of 12 judges consulted, to the effect that in time of national danger, of which the Crown was the sole judge, ship-money might legally be levied on all parts of the country by writ under the great seal. The issue of a third writ of ship-money on Oct. 9 1636, made it evident that the ancient restrictions, which limited the levying of the impost to the maritime parts of the kingdom and to times of war or imminent national danger, had been finally swept away, and that the King intended to convert it into a permanent and general form of taxation without parliamentary sanction. Payment was,

refused by Lord Saye and by John Hampden (q.v.), a wealthy Buckinghamshire landowner. The case against the latter (*Rex* v. *Hampden, 3 State Trials,* 825) was heard before all the judges in the Exchequer Chamber, Hampden being defended by Oliver St John (q.v.) and Robert Holborne, and lasted for six months. Seven of the 12 judges, headed by Finch, chief justice of the common pleas, gave judgment for the Crown, and five for Hampden. In 1639 Charles ventured again to issue a writ of ship-money, but for the comparatively small sum of £70,000. In 1641, by an Act of the Long Parliament, introduced by Selden, the illegality of ship-money was expressly declared.

SHIPPARD, SIR SIDNEY GODOLPHIN ALEXANDER (1838–1902), British colonial administrator, was educated at King's college school and Oxford, and was called to the bar in 1867. He was attorney-general of Griqualand West from 1873–7, when he was made acting recorder of the high court of Griqualand. From 1880–5 he sat as a judge of the supreme court of Cape Colony; and he was British commissioner on the Anglo-German commission in 1884–5 for settling the claims of British subjects at Angra Pequena and other parts of the south-west coast. Shippard, while at Oxford in 1878, had discussed with Cecil Rhodes the plan of the projected British advance in south central Africa. He saw in the German annexation of Damaraland and Namaqualand the first step in a design to secure for Germany territory stretching from ocean to ocean. Consequently when after the Warren expedition of 1885 he was chosen to organize the newly acquired British possessions in Bechuanaland he saw in his appointment an opportunity for forestalling the Germans, and also the Boer adventurers who likewise sought to be beforehand with Britain in the countries north of the Limpopo.

At the end of 1887 he went to Grahamstown to induce the high commissioner (Sir Hercules Robinson—afterwards Lord Rosmead) to sanction the conclusion of a treaty with the Matabele King Lobengula binding that ruler not to cede any territory to any other power than England. He failed, and then telegraphed to Cecil Rhodes at Kimberley to come and try the effect of his eloquence. Rhodes came, and by taking upon himself all pecuniary responsibility succeeded in obtaining the requisite sanction. The treaty was signed and British interests secured. Shippard thenceforth governed Bechuanaland with conspicuous success. He was administrator, chief magistrate and president of the Land Commission for British Bechuanaland, and resident commissioner for the Bechuanaland Protectorate and the Kalahari. He was created K.C.M.G. in 1887. In 1896 he played an unofficial part in the negotiations between Robinson and the Johannesburg reformers after the Jameson Raid. He then returned to England, where he died on March 29, 1902.

SHIPPING, HISTORY OF. From the dawn of history all that is adventurous and inventive in man has responded to the challenge of the sea. It was, no doubt, on inland waters that the art of navigation had its birth, in the discovery that a fallen tree would bear a man's weight down stream, and that, by the use of a pole or a rough paddle, he could check, accelerate and direct its course; but once equipped with the knowledge that what would float could also be propelled and steered, man was led irresistibly, by the quest for food and the instinct for discovery, to venture out upon the great waters.

The transition from the dug-out or the Egyptian reed-raft to the ship proper, from the river ferry service to the trading voyage, was achieved in prehistoric times. Recorded history rings up the curtain on sea-going ships equipped with oars or sails as alternative means of propulsion and with some rudimentary form of steering gear; capable of repeated voyages, with cargo as well as with passengers, between port and port. Shipping, as an industry, is as old as civilization itself. Without shipping, indeed, civilization must have been still-born. Seas and straits, mountains, marshes and deserts, set definite limits to the range and volume of migration and intercourse by land. Even to-day, water transport is easier and cheaper than land transport for the carriage of heavy or bulky commodities over long distances, and in ancient times the advantages were still more decisively in its favour. So the earliest civilizations grew up on the sea coasts or on the banks of navigable rivers, and the development of shipping, as a means for exchanging the products of distant countries, and establishing contact between races of varied cultures, has been a prime factor in all subsequent progress.

The Phoenicians.—Some scholars have believed that maritime intercourse between India and Chaldaea can be traced back so far as 3,000 B.C., and there is no doubt as to the great antiquity of Egyptian, Malay and Arabian navigation. The greatest seafarers of the ancient world, however, were the Phoenicians. Long before Solomon chartered ships from Hiram of Tyre to bring him gold from Ophir, ivory, and apes and peacocks, they had begun to plant trading depôts and colonies round the shores of the Mediterranean, and to distribute from their great emporiums, Tyre and Sidon, the products of Asia, collected by overland or coastal routes. The Phoenicians, indeed, although manufacturers as well as traders, were the first people whose greatness depended primarily on their shipping. Ezekiel's lament for Tyre presents a graphic picture of a State deriving its prosperity, like 17th century Holland, from a highly developed carrying and entrepôt trade.

The rise of Tyre and Sidon was due to their position at the meeting point between East and West. By the 6th or 7th century B.C., the overland route to the East had been supplemented by the development of a regular sea trade following the coastal routes from India to Egypt, Chaldaea and up the Tigris to Babylon. For many centuries the Levant remained the great focal centre of world commerce. The trade of the Mediterranean itself, in classical times, was shared by the Greeks with the great Phoenician colonies, such as Carthage and Utica in Africa and Gades (Cadiz) in Spain; but it was not till the *pax Romana* removed the impediments presented by perpetual wars and the scourge of piracy, that the Mediterranean era in the history of shipping could reach its full height.

The Roman Empire.—For shipping, as for other branches of industry and commerce, the earlier empire was a golden age. The Roman legions, the Roman laws, and the Roman roads made possible the manufacture and exchange of goods on a greatly increased scale, and the Roman fleets were strong enough to suppress or at least to curb, the activities of pirates. Imperial Rome itself depended, like Great Britain to-day, on oversea supplies of food-stuffs, and the annual import of 20,000,000 bushels of corn from Egypt, later supplemented by supplies from Africa, stimulated the activities of shipbuilders and shipowners.

Ships were now capable of considerable voyages. So early as the 5th century B.C., the Carthaginian Hanno had explored the west coast of Africa, and in Roman times the fleets of Juba of Numidia brought hunting dogs from the Canaries. The Phoenicians of Gades pushed up to Cornwall and the Scillies, and traded for tin with the inhabitants of Britain. Most important of all, Hippalus, in the 1st century A.D., observed the periodicity of the monsoons, and opened up the direct sea route from Egypt to India, with the result of a great increase in the traffic with the East. The Romans, indeed, deliberately encouraged the sea trade with India, in order to avoid the payment of tolls to the Parthians on the overland route, and the *Periplus of the Erythraean Sea*—a combination of "sailing directions" and commercial guide-book—bears witness to the magnitude of the traffic.

Shipping in classical times was already a well organized trade. The rights of owners, shippers, and passengers were clearly defined by law. While the ship-owner was often also the owner of the cargo, it was equally common for merchants to charter a ship, or space for the carriage of their goods. Syndicates were formed to finance particular voyages. The laws relating to bottomry (money borrowed for necessaries on the security of the ship) and to general average (the contribution made by each interest to a sacrifice, such as jettison, incurred for the common safety) were

already taking shape. Demosthenes pleaded in shipping causes. The laws of the Rhodians as to average and contracts of affreightment were quoted by jurists in comparatively modern times. Under the empire, Carthaginian ship-owners had a regular agent at Ostia; port development was systematically undertaken.

The carrying capacity of the larger ships frequently went up to 250 tons, and was much greater in some vessels employed for special purposes, such as the carriage of the Vatican obelisk to Rome. They were, however, bad sea-boats. Classical shipbuilding had developed along two lines. The galley, a long, narrow, oared craft, with great tactical mobility, was the man of war. The merchant ship was a broad, deep, sailing vessel, using sweeps only as auxiliaries, built for carrying capacity, but slow, clumsy, and incapable, owing to her very simple rig, of sailing near the wind. Winter voyages were almost unknown, and even in summer, ships seldom ventured far from land. The record passage from Rome to Egypt was nine days; the corn convoys probably took about 25 days on the direct voyage from Alexandria to Ostia; but about mid-July the Etesians, a strong north-westerly wind, stopped the direct traffic, and drove the corn ships to follow the inshore tracks along the coasts of Syria and Asia Minor. The voyages of St. Paul, with their frequent stoppages and search for a safe harbour in which to winter, were typical of all early navigation. The direct sea-route to India was an exception due to the influence of the monsoon. It was by hugging the coasts that the Phoenicians came to Britain. Even if the ships had possessed greater sea-keeping capacity, the rudimentary state of navigational science, necessitating frequent landfalls, would have made long ocean passages impracticable.

Mediaeval Shipping.—Between classical times and the beginning of modern history, there was little real progress. So long as the galley held her own as the ship of war and the merchantman was incapable of ocean voyages, the Mediterranean remained the natural centre of sea-power and commerce. After the decline of Byzantium, the Italian city States, Genoa, Pisa, and above all, Venice, dominated the trade routes with their galley fleets, and exploited them mainly with bluff apple-bowed sailing-vessels that showed little improvement on the classical models. In the north, the Norsemen appear to have used the long-ship, or an adaptation thereof, for trading as well as for fighting, but the English, French and German merchantmen of the early middle ages were sailing vessels of the old type.

The great stimulus to the development of northern shipping came from the fisheries. The importance of salt fish in mediaeval times can hardly be over-estimated. It was indispensable to inland centres during the long Lenten fast; it was indispensable as a winter provision, and for the supply of armies. The Channel and North sea fisheries were the first school of English seamanship, and the rise of the federation of Hansa towns, during the 13th and 14th centuries, was largely due to their control of the great Scania herring fishery at the entrance to the Baltic. The Hanseatics did not themselves engage in the fishery; but they purchased and distributed the bulk of the catch.

English shipping was confined, at first, to the fisheries and the short sea trades. The first impetus to longer voyages came with the third crusade, which introduced English seamen to the more advanced Mediterranean designs, and led to the promulgation of the Laws of Oléron, a codification of the existing customary law governing maritime affairs. Progress was hampered, however, by the fiscal policy of the Plantagenet kings which, aiming at revenue rather than protection, involved the grant of large concessions to foreigners. The export of wool fell mainly into the hands of the Hansa; direct sea trade with the Mediterranean was mostly controlled by the Italians; and those who controlled the trade carried the goods. The demands on shipping for war service also impeded the development of trade. The galley never became really acclimatized in England, the king's ships were few, and the bulk of the fleets were merchantmen serving on obligation of tenure, like the ships of the Cinque ports, or on requisition. With no strong standing navy, piracy was rampant, and private war, as between the fleets of Yarmouth and the Cinque ports, not uncommon. Moreover, the hire of requisitioned ships was often paid irregularly or not at all. Thus the prolonged wars of Edward III. were ruinous to ship-owners, and their complaints led, in the reign of Richard II., to the first abortive attempt at navigation laws, for the encouragement of English shipping. On the other hand, the French connection led to a brisk traffic with the English possessions, and the Bordeaux trade in Gascony wines and Toulouse woad was an invaluable nursery of seamen for the ocean trades. The pilgrim traffic to the shrine of Santiago de Compostela in Spain also encouraged the building of larger ships.

The Ocean Routes.—In the 14th and 15th centuries the art of shipbuilding made great strides. The carrying and sea-keeping capacity of the carrack, the speed and handiness of the caravel, gave an impetus to maritime enterprise, which was further stimulated by a great advance in the science of navigation. The compass had been introduced in the 12th century; the cross-staff and astrolabe enabled the latitude to be calculated. The discovery of Greenland by the Norsemen in the 10th century was the chance result of an Icelandic voyager being blown out of his course; but the exploring voyages of the Portuguese caravels down the west African coast were the product of the scientific school for navigation established by Henry the Navigator at Chagres.

There is real significance in the fact that the mother of Henry the Navigator was an Englishwoman, the daughter of John of Gaunt, for his activities foreshadowed the decline of the Mediterranean and the rise of the oceanic Powers. Yet down to the last decade of the 15th century England was of small consequence at sea. The Italians, who had already developed marine insurance on modern lines as an aid to oversea commerce, dominated both the internal and the external trade of the Mediterranean. Through their grip on the Levant, they controlled the commerce with India and the Far East. Genoese carracks and Venetian merchant galliasses carried the trade with England and Flanders. In the north the Hansa had a strangle-hold on the Baltic trade, and carried its fish, grain, and timber as far west as Portugal. Hanseatic and Flemish merchants shared with the Merchant Adventurers the export of half-made cloth from England to Flanders. Oil and wine came to England from Spain mainly in Spanish bottoms. Portugal monopolized the traffic with Guinea and the Atlantic islands. To English ship-owners remained the Gascony trade, and a share in the North sea fisheries and the voyage to Iceland for stock fish.

Before the century was over the new era had begun. The greatness of Venice and Genoa rested on their control of the rich trade with the East. As shipping and navigation improved, the oceanic Powers turned their attention to the discovery of a sea route to India and Cathay. This was the real object of the Portuguese expeditions, and in 1498 Vasco da Gama arrived at Calicut, after doubling the Cape of Good Hope. Six years earlier, Columbus, seeking a new route to Asia, discovered the West Indies. In 1497 John Cabot, with an English commission, landed in North America.

These discoveries, it must be remembered, represented voyages into uncharted seas, peopled, in the imagination of the time, with devils and monsters. The science of navigation was still in its infancy, and an error of 600 miles in reckoning the longitude was nothing uncommon. Hygiene was yet more rudimentary, and crews died like flies from scurvy and fever. Yet the spirit of adventure and the lure of trade triumphed over every obstacle. The early discoveries were followed up. In 1519–22 Magellan circumnavigated the globe. Colonization and regular trade followed hard on the heels of discovery.

The opening of a direct sea route to India, and the discovery of gold and silver in America had momentous consequences. Venice, hampered by continental wars and the advance of the Turks, steadily declined. The silks and spices of the East, the treasure of Mexico and Peru, poured into Spanish and Portuguese ports. The long Indian voyage, the colonial trade, and the slave traffic from Guinea to the colonies stimulated the building of large ships, and after the union of the two crowns in 1581, Spain stood out as incomparably the greatest of maritime Powers.

The Rise of England.—Meanwhile Henry VII. and Henry VIII. were nursing the development of English shipping by navi-

gation laws, strictly enforced in the vital Bordeaux trade, by wise commercial treaties, by laws for the encouragement of the fisheries, by the incorporation of the Trinity House in 1513, and by a bounty on the construction of large merchantmen. Henry VIII. created the first permanent navy of sailing warships.

Under Elizabeth the pent up national energies burst forth. Already Englishmen had traded, on sufferance and at peril, with Guinea and Brazil. The Spanish and Portuguese monopoly was now boldly challenged. Drake, at Cadiz, shattered the prestige of the galley. The Armada campaign revealed England as the predominant naval power. While English squadrons and privateers harried the Spanish trade, English merchantmen pushed into the Levant and along the Guinea coast. Drake's voyage of circumnavigation (1577–80), and his capture of a carrack in 1587, with the secret papers of the East India trade, opened the way to the East. Attempts to find a north-east or a north-west passage to Asia led to the opening up of trade with Russia, and to the first British settlements in North America. The grip of the Hansa was roughly thrown off. The adoption of the galleon as the English ship of war led to the development of merchantmen far superior to the clumsy Hanseatic and Flemish hulks, or the antiquated Portuguese carracks. A bounty of 5/– a ton, on the construction of ships over 100 tons, stimulated shipbuilding. Insurance of English ships and cargoes passed from Italian to English hands.

A return of 1560 (not quite complete) shows that England possessed 76 ships of 100 tons and up, 21 of them owned in London. In 1582 London had 62, and the whole country 177, and there is little doubt that this number had greatly increased by the end of the reign. Most of the larger ships belonged to the great chartered companies—the East India Company, the Levant Company, the Muscovy Company, the Guinea Company and others—by whom the bulk of the foreign trade was carried on, or to individual members of those companies; but it is clear, from documents relating to the bounty system, that many ships were built by private speculators to be chartered to merchants.

The age of Elizabeth was, nevertheless, something of a false dawn, so far as English shipping was concerned. Under the first two Stuart kings an inefficient fleet allowed Dunkirk and Barbary corsairs to swarm in the Channel, and a weak and corrupt administration hampered the development of the national energies.

The Dutch as Carriers.—Meanwhile the sturdy Dutchmen, assisted by cheap capital and business-like methods, were constituting themselves the general carriers of the world's trade. The Dutch herring fishery in the North sea had become prominent in the 15th century. At the beginning of the 17th, it employed from 1,500 to 2,000 sea-going busses every year. The import of salt for curing, and the export of the cured fish to the Baltic, and to the Catholic countries of southern Europe, employed many larger vessels, supplied Holland itself with grain, wine and shipbuilding materials, and laid the foundations of the carrying and entrepôt trade.

No nation, perhaps, has been so exclusively maritime and commercial in its interests as 17th century Holland. Its industries, apart from the fisheries, were relatively unimportant; but it had succeeded to the position of the Hanseatic League as the entrepôt for the Baltic trade, and the products of central Europe came to its ports down the Rhine. Much of the Mediterranean trade had fallen into Dutch hands, and during the Spanish war, the Dutch had ousted the Portuguese from the East Indies, and effected settlements in the West Indies and Guiana. Contemporary English authors admit that English shipowners were everywhere losing ground to competitors with better financial backing and lower working costs.

Until the strong government of the Commonwealth provided England with an efficient navy, Dutch predominance was never effectively challenged; but the East India Company, founded in 1599, still preserved a fair show of prosperity, and the political troubles in England had given a stimulus to oversea expansion. By the middle of the 17th century New England, Virginia, Maryland, the Carolinas, the Bermudas and several West Indian islands had been at least partially settled, and the demand for slave labour in the plantations foreshadowed a revival of the Guinea trade. A great new field for trade and shipping was being opened, and the one fear was that this too would fall into Dutch hands.

The British Navigation Acts.—Commercial rivalry, combined with political animosity, found its expression in the Cromwellian and Stuart navigation laws of 1651 and 1660, which confined the plantation trade exclusively to English vessels, and forbade the import of goods from European countries except in English ships, or ships belonging to the country of origin, "or to such port where the said goods can only be or most usually are first shipped for transportation." Three hard-fought wars left the British predominant at sea, and the restrictions of the navigation laws in full force. Their effect was an increase in the demand for English shipping, reflected in higher building costs and higher freights, with the result of increasing the severity of Dutch competition outside the reserved trades. At the end of the century, Sir William Petty estimated that nearly half the mercantile tonnage of Europe was under the Dutch flag, and so late as 1775, Adam Smith declared that the Dutch carrying trade was much greater than that of any other nation.

On the other hand, the growing demands of the reserved colonial trade proved a powerful stimulus to English shipping. British tonnage is said to have doubled between the Restoration and the Revolution of 1688, and all through the 18th century it continued to grow. In 1700 the total clearances of British shipping at ports in Great Britain amounted to 270,000 tons; by 1770 they had risen to 700,000. In 1771 the slave trade alone employed 190 vessels. By this time Dutch shipping was beginning to decline, owing mainly to the exhaustion consequent on continental wars. French shipping, carefully fostered by Colbert and later Ministers, is said to have employed, in 1730, about 600 vessels in the West Indian trade, and 900 in the traffic with Spain, Portugal and the Mediterranean, but it was always a somewhat artificial growth and suffered ruinous losses in the English wars. Spain, depending on treasure rather than on trade, had sunk into lethargy.

The 18th century was an era of colonization. Shipping created new markets for British goods, and the demands of those markets still further stimulated the activities of shipping. Some relaxations had to be made in the oppressive restrictions of the navigation laws, and the revolt of the United States made an irreparable breach in the whole colonial system; but British shipping continued to expand. The industry was becoming modernized. Except for the East India Company, the chartered companies had mostly faded out, leaving a clear field for the individual shipowner. The underwriters at Lloyd's Coffee House made London the greatest marine insurance market in the world and systematized the collection of shipping intelligence. The ships themselves showed no fundamental difference from those of the 17th century, but the invention of the sextant in 1731 and of the chronometer in 1735 made navigation more reliable. Great explorers, such as Captain James Cook, built up a mass of information relating to coasts, winds and currents. Charts and sailing directions became more numerous and more reliable. The compulsory registration of shipping (1786), and a number of laws regulating marine insurance and passenger traffic, brought shipping under some measure of control by the State.

Britain Becomes Predominant.—It was, however, the coincidence of the Revolutionary and Napoleonic Wars with the Industrial Revolution that gave British shipping a clear predominance over all rivals. While the inventions of Arkwright and Crompton gave an unprecedented stimulus to British commerce, the great manufacturing and trading centres of the Continent were paralysed by invasion; the French and Spanish flags were swept from the seas, and with her inclusion in the continental system, Holland finally lost her hold on the carrying trade. So great was the demand for British manufactures and colonial goods that, despite the loss of some 9,000 vessels by war risks alone, the tonnage on the register of the British empire increased from 1,540,000 tons in 1792 to 2,616,000 in 1814.

The biggest ships, ranging up to 1,000 tons or over, were the East Indiamen. Protected by their monopoly, the Company spared no expense in the production of strong, handsome, well armed ships, capable of beating off privateers, and even French

frigates, but too costly for any other trade. In the West Indies trade, competition was keen, and a faster, more economical ship was produced, averaging from 250 to 300 tons. The East Indiamen went out one year and came back the next. The West Indies traders, 700 or 800 of which often cleared in a single year, made an average of one round voyage in the year, or slightly better. Ships engaged in the trade with the Mediterranean and the north of Europe were mostly smaller and the average of all ships engaged in the foreign trade proper works out, for the years 1793–1801, at 195 tons. The average tonnage of vessels in the Irish traffic—then counted as foreign—was 80. From northern and Scottish ports the whalers, sturdy vessels, often very long-lived, set out, to the number of 100 to 150 a year, for Greenland and the south seas, often to spend two, three or even four years abroad before their return.

Among the cross-trades, those from the West Indies to North America, and from Newfoundland to Portugal with stockfish, were specially important. The coasting trade also reached great dimensions, especially the carriage of coals to London, which dated back to Plantagenet times, and gave employment to vessels larger than many of those employed in foreign trade. In 1798 the average size of colliers arriving in London was 228 tons.

Origins of Steam.—The first years of the 19th century were marked by the emergence of a rival to challenge the universal dominion of sail. The first successful steamer ever constructed was the "Charlotte Dundas," on the Firth and Clyde Canal, in 1802. In 1807 Fulton's "Clermont" began a regular service between New York and Albany. In 1812 Bell's passenger steamer "Comet" began to run on the Clyde. For some years, however, the use of steam was confined to tugs and river craft, and small passenger steamers constructed for short voyages, such as coasters and cross-Channel packets. For ocean voyages, steam was regarded as, at most, an auxiliary to sail.

Apart from the early experiments in steam, the first 30 or 40 years after the close of the Napoleonic wars saw little progress in British shipping. Now that British trade was worldwide in its scope, the navigation laws had become a clog on commerce, and a series of reciprocity treaties with various powers, beginning with Prussia and Denmark in 1824, made wide gaps in the system. The laws remained, nevertheless, in general operation, and under their protection, British shipping became lethargic and unenterprising. An obsolete system of tonnage measurement further hampered progress by penalizing breadth, and encouraging the building of deep, flat-sided, full-bottomed ships.

American owners and builders were more progressive. The high profits and big risks of the neutral trade during the Napoleonic wars had stimulated them to the construction of fast-sailing and handy vessels, and after the war they were quick to realize that speed was an asset in the carriage of mails and passengers, with the result that the Atlantic packet trade fell entirely into their hands. Everywhere they were restlessly intent on improving on earlier designs, and in 1843 the "Rainbow," the first extreme clipper ship, was turned out by a New York yard.

By that year, however, the hard driven Yankee packets had a new competitor to face in the Atlantic. So late as 1835 a cross-Atlantic steamer service had been declared a physical impossibility; but only three years later the "Great Western" and three other British ships made the passage to America under steam, and, in 1840, the British and North American Royal Mail Steam Packet Company (now the Cunard S.S. Co.), having secured a mail contract, began a regular fortnightly service, with four paddle steamers of about 1,150 tons.

From this date the sailing vessel was doomed, but few, at the time, could read the warning aright. The early steamers were too extravagant in their fuel consumption to be used for general trade or on very long voyages, and even in the mail services they required to be lavishly subsidized. The competition of steam in the ocean trades was so restricted that it had little or no influence on the last great development of the sailing vessel, due to the great gold discoveries of the mid-19th century. In their haste to be first at the diggings during the great Californian gold rush of 1849–56, people were ready to pay high for a quick passage. A demand arose for fast ships with large passenger accommodation, and the American builders responded to it by producing the finest sailing ships that had yet been seen. These Californian clippers, like "Flying Cloud" and "Andrew Jackson," were big ships for their day, with fine lines and a great spread of canvas, and there was nothing afloat that could live with them in strong winds. When the discovery of gold in Australia caused a rush of emigrants to Melbourne in 1851–56, it was from the American shipyards that British owners procured the big Australian clippers such as "Marco Polo" and "Lightning."

Navigation Laws Repealed.—Meanwhile Great Britain was moving towards free trade, and the final repeal of the navigation laws, in 1849, exposed British shipping, for the first time, to unrestricted competition in every sea. The arrival of the American clipper "Oriental," with the season's first teas from China, stung British ship-owners into an acknowledgment of the palpable inferiority of their own vessels, and a stern determination to take up the challenge.

This new-born zeal for efficiency found an echo in parliament, and the repeal of the navigation laws was closely followed by the passing of the Mercantile Marine Act in 1850 and the first Merchant Shipping Act in 1854. These laws, the parents of much subsequent legislation, were the first serious attempts to provide for the safety of life and goods at sea, and gave power to the Board of Trade to enforce reasonable standards of construction and equipment in the ships, and of competence and discipline in masters, officers and crews. Incidentally, the obsolete tonnage laws were superseded by a rational method of measurement.

Thus encouraged, and spurred on by competition, British shipowners rapidly renewed their fleets. In particular, they put into the China trade a series of beautiful little clippers, specially constructed to take advantage of every puff of wind in the light and baffling airs of the tropics. Probably no voyages have ever excited so much sporting interest as the annual race home with the new season's teas, especially that of 1866, when "Ariel," "Taeping" and "Serica" left Foochow on the same day and docked in London within a few hours of each other, 99 days out.

The California and China clippers represent the apogee of the sailing vessel; but every year the menace of steam became more insistent. The "Great Britain" (1843) was the first screw steamer to cross the Atlantic. In 1858 Brunel's monster, the "Great Eastern," was launched. Measuring 18,914 tons gross, she was a failure commercially, but as an indication of possible development she was a portent. While she was still on the stocks, the compound engine was invented, which permitted great economy of fuel, and made long voyages under steam a commercial possibility. It was first applied to long distance steamers in 1865, by the original Holt liners, which astonished the world by a nonstop run of 8,500 miles from Liverpool to Mauritius. The real death-blow to the sailing-vessel, however, was the opening of the Suez canal in 1869, which not only shortened the steamer's passage to India and the Far East, but lowered her costs, by giving her a route studded with bunker depôts at comparatively short intervals. Against such competition the sailing vessel could not live, at least in trades where speed was a greater object than cost, and the later tea clippers, such as the famous "Cutty Sark" and "Thermopylae," passed into the Australian wool trade, where the steamer derived less advantage from the Suez route.

Iron for Wood.—The transition from sail to steam was accompanied by the transition from wood to iron. Iron canal barges had been in use since the first quarter of the 19th century, and in 1825 an iron steamer began running on the Shannon; but it was not until the year 1837 that the first iron vessel was actually classed by Lloyd's Register. The later tea clippers were mostly of composite construction, with iron frames and wooden planking; but during the '60s, iron gained ground both for steamers and sailing vessels. In 1870 over five-sixths of the tonnage under construction in British yards was iron; three-quarters of the tonnage consisted of steamships.

This double transition again placed Great Britain far ahead of all rivals. The clipper ship era in the United States had been succeeded, first by a great financial depression, and then by the

Civil War, which led to the transfer of 715 American ships to British register. After the war, the energies of the American people were directed mainly to the development of their own great internal resources, and American ship-owners clung, with a strange conservatism, to wood and sail. British owners were greatly assisted by the fact that the coalfields, and the great centres of iron and steel production and engineering, were mostly within easy access to the ports, and they were quicker than any of their rivals to invest in iron and steam. In 1870 there were already 1,202,134 tons of steam shipping on British register; the United States had only 192,544 tons registered for foreign trade; France had 154,415 tons. No other country had so much as 100,000 tons.

From this point the decline of the sailing vessel was rapid, and was accentuated by the further change over, in the '80s, from iron to steel as the material for shipbuilding. In 1870 about 16% of the world's tonnage consisted of steamers. By 1890 the proportion had risen to 46%, and by 1900 to 62%, and it must be remembered that each ton of steam was equal in annual carrying capacity to three or four tons of sail. The iron wool clippers continued to struggle against the competition of steam in the Australian trade until the early '90s; but by the beginning of the 20th century sailing tonnage counted for little on ocean routes.

The Steamship and Civilization.—This tremendous revolution in maritime transport has been a prime factor in the development of modern industrial civilization. The size, the speed, and above all, the reliability of the steamer have transformed oversea commerce. There were definite limits to the possible growth both of sailing and of wooden vessels, and the 16th century Portuguese carracks of 1,500 or 2,000 tons would have been regarded as big ships in 1850. The growth of the steel steamer is limited only by the capacity of the ports. The 50,000-ton passenger liners of the north Atlantic trade are still exceptional; but the true successors of the clipper ships, ranging from 800 to 2,400 tons, are liners and freighters ranging from 5,000 to 20,000 tons.

As regards speed, the record Atlantic passage by a sailing vessel was 12 days 6 hrs. in 1854, by the "James Baines," Boston to Liverpool. The steamer record is the "Mauretania's" 4 days 10 hrs. 41 min., Queenstown to New York; but the supreme quality of the steamer is her certainty. The American clipper "Lightning" is said to have run 436 miles in 24 hours, an average of 18 knots; many cargo liners to-day are content with 12 knots. The sailing vessel, however, was at the mercy of the winds. To make her best speed she must sail at certain periods of the year, and even then her passage depended on her luck. In 1866 "Serica," a crack racing ship, was home from Foochow in 99 days; in the following year she took 120. A whole fleet of homeward bound vessels might be detained for a fortnight or three weeks off the Scillies by contrary winds. The main advantage of the steamer is not a greater maximum speed, but the fact that, on the day she puts out from port, the date of her arrival can be fixed almost with the precision of a railway time-table. So great is the superiority of the steamer over a series of voyages that, while the tonnage on British register increased 150% in the half century between 1850 and 1900, its annual carrying-power was probably multiplied by seven.

This vast increase in carrying power, coupled with certainty as to the arrival of cargoes, has had momentous consequences. In the first place it has helped to build up the populations of the newer countries by permitting a huge expansion in emigration. In the ten years 1825–34 the average annual number of immigrants received by the United States was 32,000. In the last decade before the World War it was 1,012,000. In the second place it has permitted the growth in the older industrial countries of massed populations dependent for their daily bread, and for the materials of the craft whereby they earn it, not merely on the arrival of millions of tons of imports in the course of a year, but on their arrival with absolute certainty in a steady daily stream. Finally it has raised the standard of living and broadened the outlook of people in all countries by permitting the exchange of goods on a vastly increased scale, and by facilitating travel and communication. For good or ill, our present civilization is the child of the steamship.

With the evolution of the steamer there came also a change in the organization of the shipping industry itself. In the 16th and 17th centuries the biggest ships were owned by the great chartered companies, who alone could provide the strong armaments, oversea factories and quasi-diplomatic service required in the long distance trades. In the 18th century the owners were mostly individuals or small partnerships, who might or might not be merchants, lading as well as owning the ships. At the time when steam was coming in, there were many regular lines of sailing ships, owned by wealthy firms and employed in particular trades; but a large proportion of the ships were owned on the sixty-fourth principle, by a number of persons each having an interest of so many sixty-fourths, and choosing from among themselves someone with shipping experience to act as managing owner. This system, owing to the greater cost of steamships, gradually gave way to the joint stock company, especially in the liner trades.

Liners and Tramps.—The characteristic of the liner is that she trades regularly between the same ports, running on a scheduled time-table which governs also any intermediate stoppages. In order to maintain the regularity of her sailings, an extensive and costly organization is required, with branches or agencies at all ports of call, to arrange for the collection and shipment, or discharge of cargo, and for booking passengers, if carried. Hence the liner companies have tended more and more to become large concerns, with a big publicly subscribed capital, requiring financial ability as well as technical knowledge in their management.

The "tramp," "seeker" or "general trader" has no fixed itinerary, but can be chartered, either for a definite period or for a single voyage, to carry whatever her charterer requires, usually a whole cargo of some bulky commodity, such as grain, ore or timber, between ports of his choosing. No costly organization is required; each voyage is a separate venture; each ship is a self-contained competitive unit. She may belong to a big fleet, owned by a big company; she may belong to a single-ship company, a firm, or an individual. Several small companies will often entrust actual management to an experienced managing owner.

In the early days of steam, wild speculation, especially on the sixty-fourth system, led to grave scandals in connection with overloading and the over-insurance of unseaworthy ships. The adoption of a compulsory loadline, as the result of an agitation carried on during the seventies by Samuel Plimsoll, put an end to these evils, and later legislation, together with the immense and most beneficial influence of Lloyd's and Lloyd's Register, has brought about a very high standard of safety afloat. The evils of speculation in shipping have latterly been most felt by the ship-owners themselves, through the results of a tendency to over-build in times of prosperity, which has led to every boom in shipping being followed by a long-continued slump.

The liner companies, with regular services to maintain high overhead charges, have always been particularly sensitive to rate-cutting competition. Their efforts to avoid this took two forms during the last years of the 19th century and the first years of the 20th. In the first place there was a strong tendency to amalgamation and to the pooling of financial interests by the exchange of shares between the lines. In the second place the lines in particular trades gradually organized themselves in "conferences" for the purpose of stabilizing freights at an agreed level for fixed periods. In many instances they also tied the shippers to themselves by a system of deferred rebates, which were forfeited by the shipper if he loaded goods in any vessel outside the conference lines. It was mainly as a consequence of complaints by shippers that the royal commission on shipping rings was appointed in 1906, but the lines pleaded that they could only guarantee a fast and regular service if they were assured of a steady volume of traffic at remunerative rates, and the system still persists (1929) carefully watched by the imperial shipping committee.

International Competition.—As the years went on, many of the conferences came to include lines under several flags; for shipping is an international business, and all countries are served by the ships of many nations. During the last decade of the 19th

century and the early years of the 20th, British ship-owners found their supremacy assailed by the ships of countries that were beginning to make up the leeway caused by the earlier industrial development of Great Britain. The Scandinavians, especially the Norwegians, were keen competitors in the general carrying trade. The awakening of Japan was followed by the creation of a modern mercantile marine. Dutch lines were prominent in the Far Eastern trade. France and Italy built up their fleets by a system of bounties and subsidies. Above all, German steam shipping increased from 723,000 net tons in 1890 to 3,096,000 in 1914—nearly a quarter of the tonnage on the register of the British empire. The Germans were not very successful in the tramp trade, but there were few routes on which British ship-owners did not feel the competition of the German liner companies, backed as they were by powerful financial interests.

Much of this competition was State-aided, by the reservation of the coasting and sometimes of the colonial trade to the national flag (United States, France, Russia), by shipbuilding and navigation bounties (France, Italy, Austria, Japan), and in other ways. German shipping was not directly subsidized, but British owners complained that the through rates on the German State railways were manipulated to the advantage of German shipping, and that the medical control of emigrants in transit through Germany was misused to force them to travel by German lines.

In Great Britain the early steamer companies were heavily subsidized for postal or Admiralty purposes, but from about 1875 the postal subventions were reduced to mere payment for work performed, and at no time had any State assistance been given in the construction and operation of cargo steamers. Yet British shipping still held an immense lead over its nearest rival. In the school of unrestricted competition British owners had become quick to respond to the needs of the world's commerce and to adapt the design of their vessels to the needs of particular trades. No other great maritime State placed its shipping so freely at the disposal of all countries. Many British lines ran regularly between foreign ports, and the ubiquitous tramps carried the Red Ensign wherever there was a charter to be obtained. While the freight earnings of British shipping assisted to adjust the trade balance of Great Britain, the services of the ship contributed largely to the economic development of the world, especially by distributing the products of the great agricultural countries such as Canada, Australia and Argentina, and in this way they built up new sources of foodstuffs and raw material for the British people, new markets for British manufactures, and new fields for the investment of British capital. The outstanding characteristic of British shipping at the beginning of the 20th century was the size of its contribution to that pool of fluid tonnage on which all nations draw to cope with emergency demands, or with the seasonal fluctuation in volume of traffic as between route and route.

Shipping in the World War.—The value to Great Britain of this floating reserve of tonnage was clearly seen in the war of 1914–18. From the start, the trade of the country had to be readjusted, and new sources of supply found to replace those closed by the war. About a quarter of the ocean-going tonnage on the register was taken up, in the first few months, for naval and military purposes. Soon heavy losses began to be sustained. The annual carrying-power of the remaining ships was reduced by delays arising from the frightful congestion of the ports, due to war demands, often carelessly made, on port labour and facilities. Neutral ships were frightened away from British ports by the submarine campaign. As each crisis arose it was met; first by the ship-owners alone, afterwards by directing authorities, culminating in the Ministry of Shipping, and working with and through shipping organizations such as the Chamber of Shipping, the Liverpool Steam Ship Owners' Association and the Liner Conferences. Services were readjusted to the new demands of trade; a large proportion of the ships trading between foreign ports were brought back into the trade of Great Britain to take the place of those sunk or requisitioned for war purposes.

It was the crisis caused by the submarine campaign that first really brought home to the majority of the British people, that, for about two-thirds of their annual consumption of food, and for the materials of their greatest industries, they depended on the labours of those who go down to the sea in ships, and on the enterprise and efficiency with which the ships were managed. The war brought home to them too, what manner of man the British merchant seaman is. Down to the end of the 18th century, most foreign-going ships went armed as a defence against pirates and privateers, and the British merchant seaman, by whom in those days the navy itself was manned, had proved himself a fierce and effective fighter. With the suppression of piracy, and the abolition of privateering by the Declaration of Paris in 1856, the arming of merchantmen had practically ceased, and when the German submarines broke through the accepted canons of war at sea, the seamen found themselves exposed to a deadly attack, against which they had no means of defence or retaliation. Yet there was neither panic nor holding back. Men whose ships had been torpedoed under them or blown up by mines, who had suffered hunger, thirst and cold in the long pull to land, signed on again, as a matter of course, for another voyage exposed to the same risks. When it became possible to arm them for their own defence, they used their weapons with skill and spirit, and many a mercantile skipper showed how well he could manoeuvre a ship in action.

The maintenance of supplies under war conditions was the first task of British shipping; but beyond this, it was called upon to make an immense and vital contribution to the war effort of the Allied and Associated Powers. It provided many thousands of men for the royal navy, through direct enlistment and the calling up of the naval reserves; it provided the ships and the bulk of the crews for the armed merchant cruisers that did so much of the work of patrol and convoy escort, and for the Auxiliary Patrol engaged in mine-laying, mine-sweeping, and submarine hunting in home waters. It provided the navy with indispensable auxiliaries, and carried nearly 43,000,000 tons of coal and a vast quantity of oil on Admiralty account. Without merchant shipping the battle fleets could neither have moved nor fought.

British shipping was equally indispensable to the conduct of the war on land. Practically every British soldier landed in France was carried under the British flag. British ships brought Canadian, Australian, Indian and South African troops to take their place on the western front, and carried the armies of the empire to Gallipoli, Mesopotamia, Palestine and the Balkans. When the United States came into the war, about 2,000,000 troops were transported to Europe. Of every hundred men, 49 were carried in British and 45 in American vessels.

Thus, including all movements of British and Allied troops, nurses, civilian staff, prisoners and refugees, the transport department provided tonnage from Aug. 1914, to Oct. 1918, for 23,700,000 individual passages, of which nearly one-third involved voyages of considerable length. In addition they provided tonnage for the carriage of 2,200,000 animals and nearly 50,000,000 tons of munitions and military stores, or goods, such as military fodder, which were for direct account of the British and Allied War Offices. For the Salonika expedition 26 ships, averaging over 5,000 tons, were lent to the French War Office.

British Shipping Services to Allies.—On Oct. 31, 1918, 29·5% of the total available deadweight tonnage under the British flag was in direct naval and military service. Yet this service was only a part of the contribution of British shipping to the common cause. Neither France nor Italy nor Russia had tonnage adequate to the fulfilment of their requirements for food, fuel and munitions. Again and again, at moments when the British authorities were at their wits' end to procure tonnage for military and naval requirements, without reducing British imports (largely composed of materials for the munitions industries) below the danger point, a call would come for ships to carry cereals, coal or munitions to the Allied ports, and so far as was humanly possible, every call was met. Over 15,500,000 tons of coal were carried to France and Italy in British requisitioned ships alone. Out of 5,250,000 tons of coal and munitions received by Russia during 1915 and 1916, two-thirds were carried in British ships. When France and Italy began to import meat, to supplement the rations

of their troops, they were almost destitute of insulated tonnage, and out of 1,375,000 tons purchased by them during the War, more than three-quarters were imported under the British flag. To make good the deficit of the French and Italian harvests, 2,000,000 tons of cereals in British ships were diverted during the months Aug.–Oct. 1918, over and above supplies carried by British ships already on Allied service. At the end of the War, France and Italy required 6,423,000 deadweight tons of shipping for their import services, and could provide, between them, 1,710,000 tons. The United States, all other Allies and neutrals together provided 1,611,000 tons (much of it neutral tonnage under British control). Great Britain provided 3,102,000 tons.

The bare facts are more eloquent than any rhetoric. The whole naval and military effort of the British empire and a great part of the military assistance provided by the United States, depended on British shipping. Without the assistance of British shipping the European Allies could have provided neither their armies, nor their industries, nor their people, with the supplies necessary for the continuance of the struggle. The story of the inter-Allied control of shipping is told elsewhere, but those who had most to do with it would be the first to admit how completely the execution of the whole gigantic task depended on the skilled co-operation of British ship-owners, and the daring and devotion of British seamen.

Losses and Dislocation.—The war services rendered by British shipping were rendered at a heavy cost. Apart from casualties among those who served under the White Ensign, no fewer than 14,661 officers and men of the merchant service and the fishing fleets lost their lives while engaged in trade or transport. The material losses inflicted by submarines, mines and raiders amounted to 7,759,000 tons gross, or 38% of the tonnage under the British flag in June 1914. The net reduction in ocean-going tonnage (ships of 1,600 tons gross and up), after allowing for every form of replacement, was 18%. Many of the remaining ships had suffered in efficiency through delayed repairs. The whole industry was disorganized. The tramp trade had been temporarily destroyed by the requisition of vessels for war purposes and the purchase of tramp tonnage by the liner companies to make good their depleted services. The liner services themselves had been violently dislocated in order to effect the concentration of shipping on the short Atlantic routes, which alone enabled the available tonnage to carry, in 1917–18, the essential minimum supplies. Many lucrative trades had been abandoned, for the time being, to foreign competitors.

Other nations, especially the Norwegians, whose sailors had shown extraordinary courage in maintaining the dangerous North sea trade, had suffered heavy losses, but these losses were quickly made good. The prohibition on shipbuilding for foreigners and on the sale of British ships to foreigners, imposed during the War, and maintained for some time after it, led to a great extension of shipbuilding facilities in Scandinavia and elsewhere. The huge "emergency fleet" laid down in the United States during the War came rapidly into service. Japan, whose war losses had been light, had a tonnage, in June 1920, greater by 75% than before the War. By June 1919 the world's losses of tonnage had already been made good; by June 1923 the world's total tonnage, as recorded by Lloyd's Register, was 32% greater than in 1914; but the British empire percentage (although all losses had been made good) had declined from 42·8% to 33·8%; the American (including Great Lakes tonnage) had increased from 10·9% to 26·0%.

This huge increase in tonnage was out of all proportion to actual requirements. Indeed, the volume of the world's sea-borne trade, for several years after the War, was greatly reduced as the result of that great upheaval, and the existence of a mass of surplus tonnage led, after a short post-war boom, to the worst depression the shipping industry has ever known. In Jan. 1922 it was estimated that 11,000,000 gross tons of shipping were idle for want of employment, and although the position gradually improved, as trade recovered, and as it became evident that much of the American tonnage, hastily constructed during the War, could, for all practical purposes, be written off, the supply of carrying-power was still in excess of the normal demand in 1927.

Tankers and Motor Ships.—So far as the ships are concerned, the main feature of the post-war period was the influence of oil. The tank steamer, constructed for the carriage of oil in bulk, dates back to 1885, but the increasing use of oil fuel both in industry and transport was responsible for an immense increase in the world's tanker fleets during and since the War, and one main cause of this impetus to tanker construction was the substitution of oil for coal in the bunkering of mercantile as well as naval vessels. In 1914 only 2·6% of the world's mercantile tonnage used oil under boilers, only 0·5% consisted of ships fitted with internal combustion engines. In 1927 the proportions were 28·4% and 6·6% respectively, and no less than 38% of the tonnage launched in that year consisted of motor ships.

This new revolution in motive power has its dangers for British shipping, as it diminishes the advantage derived from coal-fields within easy reach of the ports, and has combined with other factors to reduce the exports of British coal, to which tramp steamers in the trade of Great Britain look for the bulk of their outwards cargoes. It is not surprising, therefore, that British owners, while adapting many of their steamers to burn oil under boilers, and placing large orders for motor ships, have taken the lead in research and experiment directed to the discovery of a more economical employment of coal fuel, by the development of a new type of engine or the use of pulverized coal.

As regards the internal organization of the industry, the War accelerated the tendency to amalgamation and combination, especially in the liner trades. In order to maintain their depleted services, many of the big lines absorbed the fleets of other companies, or purchased tramp steamers, with the result of bringing a still larger proportion of the total tonnage under the ownership or control of a few powerful groups. The tramp trade itself has been heavily hit by the decline in British coal exports and by the slackness of demand due to a surplusage of carrying-power. The line of demarcation between tramp and cargo-liner tonnage is not always clear; for many tramp owners put their ships "on the berth" for consecutive voyages to a particular port, during the busy season, and many liner companies place some of their vessels on the open freight market, when not required for their regular services. There is no doubt, however, that the lines have gained, and the tramps lost ground since the War; but the necessity for coping with seasonal fluctuations will always provide employment for tramp shipping, and any large increase in the volume of world trade will lead to a revival of demand.

Shipping Policy.—In shipping policy two contrary tendencies are at work. The spirit of economic nationalism arising from the War has found expression, in many countries, in a tendency to foster, by subsidy or protection, the national shipping, and to discriminate against foreign flags. The other tendency springs from an increasing sense of the international character of the shipping industry, and its absolute dependence on the free movement of the world's trade. It has found expression in the slogan of British ship-owners—"freedom of the seas in the sense of equal treatment of all flags in all ports," and can be seen at work in the conventions on ports and flag discrimination concluded under the auspices of the League of Nations, and in the efforts of such bodies as the International Ship Owners' Conference and the International Maritime Law Committee to procure uniformity of law and practice in such matters as safety regulations and equipment, the conditions of employment afloat, ship-owners' liability, and shipping documents.

It is natural that British ship-owners should have taken the lead in this movement, for, while the percentage of tonnage under the British flag is smaller than before the War, the British merchant navy is still much larger than that of any other nation, and takes a much larger share in the general carrying trade of the world. That position is likely to be retained, for geographical position, an indented coastline, coal and iron in close proximity to the ports, and an accumulated capital larger than can be absorbed in the development of her internal resources, all draw Great

Britain to the sea. Shipping, however, is only the handmaid of commerce, and the future prosperity both of British and of the world's shipping depends on the demand for transport created by the peaceful development of the world's resources, and on the ability of the ship-owners to meet that demand by supplying cheap and efficient carrying power. In the past it was the glory of shipping to extend the range of civilization by the discovery and exploration of new countries, and by enabling their empty spaces to be peopled from the surplus population of the old world. The period of discovery is over; the world has been mapped and charted. The tide of emigration has slackened with the growth of the new communities oversea. It remains for shipping to continue its beneficent task of redressing the uneven distribution of the world's natural resources by a system of exchange which renders the products of all climes available in all countries to the benefit of all peoples.

SHIPPING: MERCHANT SHIPS OF THE WORLD.

In spite of the wealth of literature dealing with the sea and ships, there is very little information about the size of the fleets of the seafaring nations of the world before the nineteenth century. Mulhall estimates the total world tonnage of shipping in 1800 at 4,026,000 tons. This is probably an under-estimate. Sir Henry Petty, writing about 1666, estimated the whole of the shipping of Europe at 2,000,000 tons distributed as follows:—

	Tons
English	500,000
Dutch	900,000
Hamburgers with the subjects of Denmark and Sweden in the town of Dantzic	250,000
Spain, Portugal and Italy	250,000

If Petty's figures are reliable, the English must have considerably improved their position relatively to the Dutch in the first half of the 17th century, for Sir Walter Raleigh writing in 1603/4 states: "We send into the East Kingdoms yearly only one hundred ships, while the Shipowners of the Low Country send thither about three thousand ships." He estimated that the Low Countries at that time possessed as many vessels of all sorts as eleven kingdoms of Christendom including England and that they built one thousand ships annually. The sailing ships in which the seaborne trade of the world was carried in the middle ages would to-day be considered of very moderate size even in purely coasting trade. Vasco de Gama rounded the Cape of Good Hope in 1497 with three vessels, the largest of which is described as of 120 tons and the first voyage round the world was accomplished by Magellan between 1519 and 1522 with five vessels, the largest of which was only 130 tons. Vessels of greater size were, however, built and King Henry VIII.'s "Harry Grace a Dieu"—the Great Harry—is listed at the head of the inventory (given after Henry VIII.'s death) as of 1,000 tons.

The average size of 152 ships in the Spanish Armada was 389 tons. The English fleet consisted of 76 of the Queen's ships averaging 121 tons each. The combined tonnage of the Spanish and English fleets was probably less than that of three or four modern transatlantic liners. More or less accurate statistics at any rate for the United Kingdom, the British colonies and the United States of America become available at the end of the 18th century, or roughly from the time of the appearance of the steam vessel. The first patent for a steam engine appears to have been taken out in 1786 and a small steamer was constructed and employed in towing on the Forth and Clyde canal in 1803.

According to a Custom House return of 1830 there were 11 steam vessels of 542 net tons belonging to the United Kingdom in 1814. Of these only one steamer of 69 net tons was registered. The 10 unregistered vessels were presumably river craft so that so far as sea-going shipping is concerned the year 1814 may be taken as the official beginning of the steamship era in British merchant shipping. In the United States records one steam vessel of 78 tons is shown for the year 1807 and 14 steam vessels of 2,917 tons for the year 1814. An accurate statistical account of the development of merchant shipping in the United Kingdom and in foreign countries since 1814 is rendered difficult by the fact that some of the relevant figures are given in net tons and some in gross. The official statistics of the United Kingdom are expressed in net tons throughout, with alternative equivalents in gross tons for later years, but when comparative figures are required for foreign countries reliance has to be placed on the records published by Lloyd's Register of Shipping, and these have in recent years been expressed in gross tons only. In the following tables gross tonnage has been converted into net. The conversion ratios vary with the period of build of the ship, and the appropriate ratios have been estimated from the data available.

Tables of British Shipping.—Mulhall gives the following totals for British and Colonial shipping up to the year 1800.

Year	British and Colonial shipping	
	Vessels	Net tons
1588	470	37,400
1610	910	83,000
1666	1,320	120,000
1688	2,620	210,000
1702	3,260	261,000
1760	5,730	487,000
1800	17,410	1,856,000

The table on p. 549 shows the tonnage of the merchant shipping on the register of the United Kingdom from 1791 to 1927, so far as the records are available for the earlier years, in some detail for the period 1860 to 1890 when the rate of replacement of sailing vessels by steam vessels was particularly rapid, and yearly from 1914 to 1927.

In 1870 the tonnage of sailing vessels was four times as great as that of steam vessels. By 1900 the position was reversed. The growth of the effective carrying power was much greater than is indicated by the mere tonnage figures as the steam vessel made three or four voyages for every voyage of the sailing vessel. The total tonnage owned in the United Kingdom was reduced by nearly $2\frac{1}{2}$ million net tons between 1914 and 1918 by reason of war building failing to keep pace with war losses. Since the war the highest total reached was at the end of 1925 when it was practically the same as at the end of 1912. The depression in shipping in the last few years has discouraged building and has accelerated the scrapping of older vessels, and tonnage on the register at the end of 1927 was more than a million tons less than at the end of 1925. Since 1923 the Board of Trade returns show motor ship tonnage on the register separately. The increase from 263,000 net tons in 1923 to 765,000 net tons in 1927 is not so great either absolutely or relatively to the total tonnage on the register as was the increase in steamship tonnage from 2,723,000 tons in 1880 to 3,973,000 tons in 1885 and to 5,043,000 in 1890.

Number and Tonnage of Registered Vessels Belonging to the United Kingdom Including Jersey, Guernsey and Isle of Man, at the End of Each Year

NOTE.—In 1827 the new Registry Act came into operation under which owners of ships were obliged to register anew. Many vessels that had been previously lost had been continued up to this time on the registry, no evidence of their loss having been produced.

World Shipping.—Only approximate world figures are available for the earlier years of the 19th century. In the following table the figures for the years 1886 to 1927 have been prepared from returns published by *Lloyd's Register* and the Bureau Veritas. The earlier figures are estimates collected by Mulhall. The more recent figures have been converted from gross tons to net so as to make them comparable with the earlier figures and with the preceding table applicable to the United Kingdom.

World's Mercantile Marine at Various Dates from 1800 to 1927

Year	Steam*	Motor	Sail	Total

*Including motor ships prior to 1914.

The world's mercantile marine doubled itself between 1666 and 1800 from the 2 million tons of Sir Henry Petty's estimate to the 4 million tons of Mulhall's estimate and increased tenfold between 1800 and 1922 from 4 million to 41 million net tons. Motor ship tonnage has increased from 146,000 tons in 1914 to 2,576,000 tons in 1927 and the same comment can be made as on the United Kingdom table that this increase is not so great either absolutely or relatively as the increase in steamships between 1860 and 1870 or between 1870 and 1880. The world's merchant shipping was on the whole increasing at a rapid rate during the period. Sailing ship tonnage was increasing until 1860, roughly stationary until 1880 and has, on the whole, been steadily declining since that date.

The relative positions of the merchant fleets of the chief maritime nations for the last 40 years can be studied from the published records of Lloyd's Register of Shipping which go back to 1886.

The table on the following page shows the steam (including motor) and sailing ship tonnage for June of the years 1886, 1914, 1920 and 1927. Vessels of under 100 tons gross are omitted from Lloyd's Register figures.

In 1886 the United States occupied the second place numerically, but much of its shipping was employed on the Great Lakes and in the reserved coasting trade, and Norway came immediately after the United Kingdom among world carriers. The columns of the table headed "1914" show the position immediately before the World War. The United States had dropped to third place and more than half of the 4·3 million tons of United States steam shipping was employed exclusively on the Great Lakes.

Germany was by far the most important shipping country in the world after the United Kingdom. The figures for the year 1920 are inserted in the table as showing the position immediately after the war better than the figures for 1918 or 1919. Early in 1920 Germany surrendered all her larger vessels to the Allies under the terms of the Peace Treaty and her steam tonnage was reduced to 419,000 gross tons, or less than she had in 1886.

The United States total had increased to over 14½ million tons of steam and motor shipping, of which about 12½ million gross tons was ocean-going. This huge increase in American shipping followed the completion during 1919 and 1920 of the building programme entered upon in the last years of the war. Much of

Tonnage of the Vessels of 100 Tons and Upwards Belonging to Each of the Several Countries of the World as Recorded in Various Editions of Lloyd's Register Book

this tonnage was of doubtful value, nearly 2 million tons consisting of wooden vessels. During the last seven years, American tonnage has been steadily reduced while Germany has been slowly rebuilding her merchant fleet, and she is well on the way to regain her prewar position.

Japan, Italy, France and Norway have all considerably improved their relative positions since 1914.

The British Empire owned 63·6% of the mechanically propelled shipping in the world in 1886, 35·2% in 1914, 37·4% in 1920 and 34·6% in 1927. (L. I.)

THE UNITED STATES

In the 19th century United States shipping passed through stages of brilliance (*see* SHIPPING, HISTORY OF), gradually fading and declining into an inconsequential factor in the world's carrying trade, to be revived again since the World War in a new effort to provide United States cargoes with ships of the same nationality suitable to convey them to their respective destinations.

Early in the history of American independence the shipping industry was pre-eminent among the industries developed on the western side of the Atlantic. At that time the United States was primarily a seacoast country, and overland transport had not been sufficiently developed to make exploitation of the interior convenient, while the size of the population did not make it urgent. Inter-state transport was chiefly by water, as was, of course, transportation between the states and the European sources of articles whose manufacture was not yet developed in America. Materials for wooden ship construction were to be had cheaply and at locations convenient to the coast. Therefore a large shipbuilding industry was set up and flourished along the North Atlantic seaboard.

Soon after the United States became independent, its government established a policy of industrial protection. This policy was extended to shipping and resulted almost immediately in a rapid increase of the volume of seagoing tonnage under the American flag. This is indicated in the table at the bottom of the page, authority for these figures being the bureau of research of the United States Shipping Board.

*Includes canal boats and barges.

The table in col. 2 of the preceding page shows United States shipping reached a peak at the time when sailing vessels were at the height of their development. In this type of shipping, United States shipowners and shipbuilders enjoyed advantages in the cost of construction of vessels which did not continue with the incoming of the steam ship. Almost simultaneously with this latter development, came the development of the railroad, large increases in the population, and a natural instinct, fostered by the government, to explore and settle the interior regions of the United States; all of which combined to divert national interest away from the sea. In the table below is shown the percentage of United States cargoes carried in United States vessels over a period of about one hundred years.

Year	Percentage of U.S. cargoes carried in U.S. ships	Year	Percentage of U.S. cargoes carried in U.S. ships
1830 . .	89·9	1900 . .	9·3
1840 . .	82·9	1910 . .	8·7
1850 . .	72·5	1920 . .	42·7
1860 . .	66·5	1924 . .	36·3
1870 . .	35·6	1925 . .	34·1
1880 . .	17·4	1926 . .	32·2
1890 . .	12·9		

The outbreak of war in 1914 indirectly resulted in a severe dislocation of ocean traffic through American ports due to the diversion of European vessels regularly operated in the United States trades to military usage. This situation gave rise to Congressional consideration of the shipping problem which resulted in the passage of the Shipping Act of 1916. This act was designed to create a board which would regulate shipping passing through American ports and make researches which would lead the way for further development of a national shipping programme. With the entrance of the United States into the World War and following the call on its government for ships to assist the Allies in conveying troops and supplies across the Atlantic, the shipping board was utilized by the president of the United States as an agency for carrying out the largest shipbuilding programme of history.

In the course of this programme covering a period of four years, a total of 2,314 ships, aggregating 13,636,967 deadweight tons, was built. In addition to the construction of vessels, much tonnage was secured from other sources. The entire programme is indicated in the following table:

	Number of vessels	Aggregate deadweight tons
Constructed . . .	2,314	13,636,967
Seized from enemy alien owners	105	675,441
Purchased	103	368,305
Transferred to shipping board from other government departments . .	21	25,504
Total	2,543	14,706,217

Hostilities ceased prior to the time construction on the majority of the new tonnage was completed, but most of it was well on the way before the signing of the armistice and contracts for its completion have been made.

To solve the problem presented by this fleet's existence the Merchant Marine Act of 1920 was passed. This act undertook a plan to transfer the fleet to the ownership of citizens of the United States who would operate it privately, and devised means of aiding them in their operation so that they might compete on an equal footing with ships of other flags operated under conditions more favourable to their owners. The act likewise directed the shipping board to operate vessels over trade routes essential to American commerce when it was not possible to effect transfer to private ownership to the end that all trade routes necessary to the maintenance of United States foreign trade should be served by United States ships. In many cases, this move was necessary, and in all, the shipping board established 35 shipping lines, 16 of which had been sold to citizens of the United States by the end of 1928.

In the practical operation of the Merchant Marine Act of 1920 it was found that the aids provided to assist private operators in meeting foreign competition in many trade routes were not adequate. Thereupon Congress considered the matter anew and passed the Merchant Marine Act of 1928 wherein it increased the construction loan fund, provided for in the previous act, to $250,000,000, and made it possible for shipowners to borrow up to 75% of the cost of the construction of vessels at the rate of interest which the government pays on current borrowings. It also extended the period for which mail contracts may be made from one year to ten years and increased the amount of compensation to be paid for the carriage of mail in United States ships.

See W. S. Lindsay, *History of Merchant Shipping and Ancient Commerce* (1874–76); Lloyd's *Register* of Shipping (annual); Bureau Veritas (Annual); House of Commons Papers; Annual *Statement* of the Navigation and Shipping of the United Kingdom; *Statistical Abstract* of the United Kingdom; Annual *Report* of the Commissioner of Navigation, Washington.

SHIPPING, MINISTRY OF, one of the temporary British departments of State brought into existence when Lloyd George became prime minister in Dec. 1916. Shipping had long been recognized within a limited circle as a vital factor in the prosecution of the World War, but it was only about this time that the intensification of the submarine campaign, coupled with the ever-growing military demands upon sea transport, gave grounds for real anxiety in regard to the shipping resources of the Allies.

The object in view was thus to bring all the shipping available under the control of one authority to ensure its most economical employment under war conditions and for war purposes.

The Development of the Shipping Problem.—At the outbreak of war Great Britain stood easily first among mercantile nations, Germany, whose ships were compelled from the beginning of the conflict to seek safety in port, being her only competitor. The possibility that the available tonnage might prove insufficient did not therefore at first enter into the calculations of the Government, though there was ground for anxiety lest ships be prevented from putting to sea and a successful scheme of insurance against war risks had been carefully worked out beforehand. No ship was prevented from going to sea by lack of crew, though at one period on certain routes the loss of one ship in three was almost certain. Once the continued employment of the ships had been assured there seemed at the outset to be no cause for anxiety as to the sufficiency of the 18,000,000 tons of ocean-going ships with which Great Britain entered the war. Ships were taken up for service with the fleet and as transports as occasion arose, the vast majority remaining free to fulfil their normal functions, subject only to restrictions imposed in the interests of safety. It was not until the war had been in progress for more than a year that the conservation of shipping by eliminating unnecessary demands began; in 1916 the restriction of imports as a means of relieving the pressure upon tonnage was first embarked upon. (*See* War Control of Shipping.)

The possibility that shipping might prove a governing factor when once realized was not allowed to escape from view, and the facts were not less patent to the enemy. Intensified activity followed on both sides. The submarine campaign became a definite challenge upon the issue of which all Germany's hopes were centred. The establishment of the Shipping Control Committee (*q.v.*), marked the beginning of the new phase, and the constant occurrence of new demands handled by different governmental authorities tended to throw the economic system of the country out of gear and led to a risk that necessary services might be starved while surplus tonnage was seeking profitable but nationally disadvantageous employment elsewhere.

The Pre-existing Organization.—Prior to the creation of the Ministry the two authorities directly concerned with merchant shipping were the Transport Department of the Admiralty and the Board of Trade. The primary function of the former was to select, if necessary equip for service, and direct the movements of, the ships required by the Navy, and during the war its responsibilities expanded rapidly. Its activities however did not extend to matters coming within the purview of the Board of Trade, the

pre-war responsibility of which, so far as shipping was concerned, was limited to regulating in the interests of passengers and crew the conditions under which ships were employed. This responsibility was extended during the war to include such measures of control as became necessary in connection with other activities of the Board, which, *inter alia,* is responsible for watching the general economic condition of the country, and in that capacity it had to devise measures for checking developments which appeared to threaten British economic welfare. Two Committees were set up by the Board in November 1915 with that object. The first—the Ship Licensing Committee—could debar any British ship from undertaking a voyage which for any reason was not approved. The second—the Requisitioning (Carriage of Foodstuffs) Committee—directed British shipping into channels which would assist the importation of food or other necessities. The Board of Trade also from the outbreak of war undertook direct responsibility for, and transport of, all imports of frozen meat. It also saw that the interests of the Mercantile Marine were not overlooked in the competition for materials and for vacant slips in the ship-yards.

The Trade Division of the Admiralty, primarily concerned with the regulation of the movements of British ships from the standpoint of safety, developed during the first two years of war important functions in relation to neutral shipping by means of a system of control of British bunker coal; and at the end of 1915 the Port and Transit Executive Committee was set up to expedite the flow of traffic through the ports.

The Internal Organization of the Ministry.—The Ministry was organized upon the usual model of a Department of State. The Controller, Sir Joseph Paton Maclay (afterwards Lord Maclay), was a member of the Cabinet, though not of the War Cabinet. He was not a member of the House of Commons and declined to seek election, questions in the House being answered by the parliamentary secretary, while on occasions of exceptional importance a member of the War Cabinet was available to state its case.

The staff of the Ministry was drawn from a variety of sources. The Transport Department of the Admiralty was transferred to it en bloc, also certain small sections of the Board of Trade; and as the work grew, the necessary personnel was obtained by the temporary transfer of trained civil servants and by volunteers from shipping firms.

At the outset the Admiralty was inclined to regret the loss of control necessitated by the creation of a separate Ministry of Shipping, but the difficulty was solved by a compromise, the Director of Transport (the Chief Executive Officer of the Department) becoming directly responsible to the Board of Admiralty for all shipping employed on naval service, the Admiralty retaining the right to order the movements of the shipping on which they depended for their supplies.

The Shipping Control Committee became in effect the Council, or supreme deliberative body, in the Ministry and was constantly consulted by the Controller, who addressed himself from the first to the question of increasing the available supply of shipping. At home the scarcity of material and labour and the competing demands of the Navy had brought the output of the yards to far below their normal capacity. It was decided to concentrate on the production of standardized cargo vessels of the simplest design; and the co-operation of the shipbuilders was secured. Simultaneously steps were taken to place contracts with shipbuilding yards abroad—in Japan, the United States of America and Canada, and the resources of every firm at home or abroad which had berths available were utilized to the utmost.

After a few months the responsibility for all shipbuilding was transferred to the Controller of the Navy, but the Minister of Shipping continued to keep in close touch and the marked improvement in the output of new merchant tonnage which helped to relieve the situation later in the war was largely due to the programme which he had drawn up.

The executive work of the Ministry was under the Director of Transport and Shipping, an officer who had previously been Director of Transport under the Admiralty; his immediate assistants were also styled directors, dealing respectively with technical matters, with the selection and allocation of ships to the various services, with the management of the various classes of transport, naval, military and commercial, and coastwise shipping under private control, and the work of the port.

To the secretariat was assigned the handling of questions concerned with general policy and the conduct of correspondence with other departments and with the public in connection therewith. It also dealt with all establishment questions and was responsible for all business not definitely assigned to one or other of the executive branches, such as negotiations for securing the control of neutral tonnage, and the work of the National Maritime Board,—a body consisting of representatives of owners and employees, set up to settle questions connected with the pay of officers and men of the Mercantile Marine.

The Tonnage Priority Committee decided between competing claims for freight and scaled down the programmes of the various import services, bringing them within the scope of the tonnage available.

The Ministry relied on the estimates of the Statistical Branch and, when it became necessary to bring under a single control the tonnage resources of all the Allies, the Allied Maritime Transport Council (*q.v.*) was set up. A small Legal Branch was set up to advise upon questions arising in day-to-day administration of the Department and to represent the Ministry in Admiralty adjudications in regard to compensation for ships lost upon Government service.

The financial work of the Ministry attained very large dimensions for with practically the whole of British shipping under requisition, enormous sums were payable in monthly hire, and heavy claims for loss and damage to ships had to be met.

(J. A.)

SHIPPING: REGISTRATION, CLASSIFICATION AND STATE REGULATION. Registration.—It is essential that every ship should have a certificate of identity, or of registry, for facility in maritime trading. The Navigation Acts of Great Britain from 1660 onwards made the registration of vessels compulsory, and this requirement is still contained in the Merchant Shipping Acts.

To obtain a certificate, an application must be made by the owners, stating their qualifications for ownership and their financial interests. A certificate from the builders must be produced giving a description of the ship, the estimated tonnage, and the time and place of build. A surveyor of the Board of Trade measures the vessel for tonnage and for registration, and prepares a certificate of particulars which include the draught marks at the bow and stern. The registrar then issues a certificate ("carving note") which gives the vessel an official number and which states the registered or net tonnage and the port of registry. The builder thus authorized cuts the official number and the registered or net tonnage in the steel structure of the ship (usually on the beam at the after end of the main hatchway, immediately before the bridge), marks the port of registry and the name of the ship on the stern, and the name only on each side of the bow, the draught marks having already been marked and checked by the surveyor. The necessary particulars are then entered in the official register, and a certificate of registry in conformity with these particulars, but to which is added the name of the master, is given to the owners. As there is often some confusion as to what is meant by "registered tonnage," it should always be remembered that this term is usually applied to the net tonnage, that is, the tonnage on which dues are assessed, and is the tonnage which is marked on the ship for purposes of identification. (For particulars of measurement *see* SHIPPING: *Tonnage Terms.*)

Lloyd's Register.—There are certain societies formed by the sea interests which have for their purpose what is termed the classification of ships. The most famous and influential as well as the oldest of these bodies is Lloyd's Register of Shipping, which was founded in 1760 and reconstituted in 1834 "for the purpose of obtaining for the use of Merchants, Shipowners and Underwriters a faithful and accurate classification of mercantile shipping, and for their government adopt from time to time a code of rules and regulations," and which may be taken as a standard to illus-

trate the important part played by classification societies in the working of the mercantile marine. The society prints annually a *Register Book* containing the names and particulars of all the ships in the world over 100 tons gross, and where the vessels are classed with the society the characters assigned with full particulars are given. It publishes, at regular intervals, certain valuable statistical summaries of the position of shipping with reference to its growth, change, and so forth, which are regarded by the shipping world as its "barometer." and which form a sensitive index of the position of the world's trade generally.

The rules fix the quality and strength of the material to be used in the construction, the thicknesses of the parts of the hull, the equipment of anchors and cables as well as the requirements for machinery. The use of the expression "A1 at Lloyd's" as a hall-mark of excellence indicates that from the design stage to the end of its existence the fitness of the ship is under control. When a new ship is contracted for, plans of the design showing details of the various parts of the structure are submitted and amended where necessary. The materials to be used in the construction are tested by the society's surveyors, and its officers supervise the actual building of the ship and its machinery. When it is completed a certificate is issued to the effect that the general regulations and practice of the society have been complied with, and the character or symbol of classification is attached to the vessel's name in the register of the society. The ship enters into service, and at regular intervals—generally every four years—is required to undergo a special survey and overhauling at the hands of the surveyors, under specific regulations.

Lloyd's Register of Shipping is voluntarily maintained by the shipping community, and is governed by a committee composed of the most representative men in the various branches of the industry—shipowners, underwriters, and ship and engine builders. It has similar committees in the United States, France, Holland, Sweden, and Japan. It thus forms a link between the sea-faring communities of the world which cannot be supplied by international political means, and forms a community of sea-faring interests whose purpose is to ensure the fitness of ships. Its highly trained technical experts are to be found in every centre of shipping activity in the world. (*See* LLOYD'S REGISTER OF SHIPPING.)

Classification Societies.—Most countries have set up their own national classification societies, in some instances partly under Government direction. These comprise the Bureau Veritas, with headquarters in France; the Norske Veritas, with headquarters in Norway; the Germanischer Lloyd, with headquarters in Germany; the American Bureau, which was resuscitated when the United States entered the World War; the Registro Italiano in Italy; and a Society in Japan of very recent origin; these societies differ somewhat in the particular symbols which they attach to the various classes. Although their printed regulations for the construction of ships and machinery do not differ greatly, there are differences of practice in regard to the administration of the various rules. The principal classification societies in 1927, and the tonnage of vessels (steam, motor and sail) classed, were:—

	Tons gross
Lloyd's Register of Shipping, with headquarters in London	29,605,303
British Corporation for the Survey and Registry of Shipping, in Glasgow	4,484,782
American Bureau of Shipping, at New York	8,580,532
Bureau Veritas, at Paris	5,870,900
Germanischer Lloyd, at Berlin	3,837,222
Norske Veritas, at Oslo	1,847,334
Registro Italiano, at Genoa	2,712,316

It will be seen that the major portion of the total tonnage owned in the world, which in 1927 was some 63 million tons gross, plies under the aegis of one or other of the principal classification societies—a clear indication that, to the world's mercantile marine, classification is an indispensable adjunct.

The Bureau Veritas was founded in Antwerp in 1828, to make known to underwriters the qualities and defects of ships frequenting Dutch and Belgian ports. In 1832 the headquarters were moved to Paris, and in due time its influence spread to countries where shipowning or shipbuilding existed. In 1851 rules were drawn up for the construction of wood ships, and about 1867 for iron. Rules for steel came later, and also rules for the construction of machinery, and as circumstances arose provision was made for special types, such as oil-tank vessels, turret vessels, and dredgers, as well as for the testing of materials. These rules have been revised from time to time, and special rules issued for ships intended for inland waters, for yachts and for motor boats.

The British Corporation was founded in 1890, and obtained its charter under the Merchant Shipping Acts for the assignment of freeboards; its first rules were issued in 1893. Its inception was due to the enterprise and influence of a number of leading shipowners, shipbuilders and engineers more particularly connected with Glasgow and the west of Scotland, the first aim of the founders being to provide an independent society thoroughly capable of dealing with the complicated questions which were likely to arise under the Load Line Act then coming into operation. The Liverpool Registry, which had once been independent, had been absorbed into Lloyd's Register some years before, and it was thought that the enormous shipbuilding interests of the country demanded the existence of a society whose friendly rivalry with the great society of Lloyd's Register would have a beneficial influence on the shipbuilding of the country. The British Corporation have a working agreement with the Registro Italiano, the American Bureau of Shipping, and the Imperial Japanese Corporation, which provides for the mutual recognition by these bodies of the classification and survey of vessels conducted by them.

The American Bureau of Shipping, established in 1867 as the Record of American and Foreign Shipping, was resuscitated as the result of the large construction of merchant ships built by the United States for their use in the World War, and is officially supported by the United States Government.

The Norske Veritas was established in 1894 by the various marine insurance clubs of Norway. Previously each club had its own separate staff of surveyors, on whose report depended the class of the vessel and the premium to be paid. As ships rose in value and reinsurance became the rule, a desire for mutual protection led to the establishment of the Norske Veritas with one uniform system of classification and valuation.

The Germanischer Lloyd was established in 1867, and reorganized as a joint-stock company in 1889. Its functions are carried out by officers at the central office in Berlin, assisted by a staff of surveyors in Germany and at the principal foreign ports—the latter under control of agents, who are mostly consuls. In all foreign parts in which the Germanischer Lloyd has no representative, the German consuls are required by order of their Government to exercise the functions of an agent of the Germanischer Lloyd.

The Registro Italiano was first founded in 1861, and has passed through many changes of late years, the first of which occurred in 1910, when it was reconstituted as the Registro Nazionale Italiano. Later it became the Registro Navale Italiano, and after the World War, was amalgamated with the other Italian institution, the Veritas Adriatico, by the wishes of the Italian Government, in order that one Italian Register of Shipping should be established, under the name Registro Italiano.

The highest class assigned by the societies upon the completion of a ship is marked as follows:—

Lloyd's Register	✠100A1 ✠LMC
Bureau Veritas	✠Ⓘ$^3/_3$L 1,1
British Corporation	B. S.* M. B. S.*
Norske Veritas	✠1A1 ✠MV, KV
Germanischer Lloyd	✠100$\underset{4}{A}$ ✠MC
Registro Italiano	✤100A1, 1, L
American Bureau	✠A1Ⓔ ✠AMS

The star or cross in each case denotes special survey during construction. In Lloyd's Register 100A refers to conformity with the rule requirements; the figure 1 to the efficiency of the equipment of anchors and cables; LMC denotes Lloyd's Machinery Certificate. In the Bureau Veritas the encircled I expresses the first division of classification (out of three), the two rings denoting that the ship is divided into a sufficient number of watertight

compartments to enable her to float in still water with any two open to the sea; $^3/_3$ expresses completeness and efficiency of hull and machinery; the letter following $^3/_3$ indicates the navigation for which the vessel is intended, L signifying unrestricted ocean trading; the first 1 shows that the wood portions of the hull are entirely satisfactory, while the second 1 has the same significance in respect to the equipment of masts, spars, rigging, anchors, cables and boats. In the British Corporation Register, B.S. signifies conformity with all requirements, these letters standing for British Standard; M.B.S. signifies that the machinery also conforms. In the Norske Veritas 1A1 denotes compliance with rule requirements as regards the hull; MV and KV signify that the vessel has a Norske Veritas certificate for engines and boilers. The third figure A denotes the efficient state of the equipment. In the Germanischer Lloyd the mark 100 $\underset{4}{\mathbf{A}}$ signifies that the ship, including equipment, fulfils the requirements of the highest class of the society. The figure 4 indicates that the class is to be regularly renewed after special surveys held in periods of four years each. MC signifies that the machinery conforms with the rules and has obtained a separate certificate. In the Registro Italiano 100A refers to conformity with the rules, the first 1 to the equipment of the hull, and the second 1 to the equipment of the propelling power (whether sails or machinery). The letter following the class indicates the navigation for which the ship is intended, L signifying unrestricted ocean trading. In the American Bureau, A1 denotes conformity with the rules, E referring to the equipment, and AMS signifies American Machinery Survey.

State Regulation.—In Great Britain the State maintains control in matters concerning the safety of life at sea, while leaving much to the sea-faring interests as far as the safety of ship and cargo is concerned. Thus, for instance, while the classification certificates of Lloyd's Register are accepted as sufficient evidence that the vessel, her machinery and equipment are in a proper seaworthy condition, yet when it comes to the provisions for the safety of crew and passengers the Marine Department of the British Board of Trade sees that proper provision is made for

(a) the accommodation for crew and emigrants;
(b) boats and life-saving appliances;
(c) wireless, navigation fittings and control;
(d) the carriage of special cargoes such as wood, grain and coal;
(e) the marking of the proper load line of a cargo ship, and
(f) the subdivision of passenger vessels.

Authority is given to the Board of Trade by the Merchant Shipping Acts of 1894 to prepare and to administer regulations necessary for safety at sea, of which the principal are those relating to the marking of a load line.

Loadlines: (a) *Cargo Vessels.*—The loadline is not a modern feature, for the vessels of the Italian republics probably before A.D. 1000 had a mark printed on their sides to indicate that the ship should not be loaded beyond this point. The Sardinian mark was the centre of a painted ring—practically the same as to-day. The modern story of the loadline is less than a century old, for about 1835 the committee of Lloyd's proposed that a freeboard of 3 inches per foot depth of hold should be used as a guide for safe loading. The freeboard or free side was the vertical distance from the upper (*i.e.*, the top continuous) deck to the waterline, and Lloyd's rule approximately stated that this freeboard should be ¼ of the depth of the ship. While other rules were also tried, the first definite proposal to deal logically with the relation of freeboard to size and type of ship was sent by the Institution of Naval Architects to the Board of Trade in 1867. In 1871 a Merchant Shipping Act was passed requiring a scale of feet to be marked at the bow and stern showing the draught, and authorizing the Board of Trade to appoint persons to record the draught of water of vessels leaving port. Lloyd's Register of Shipping, in about 1873, required what were known as Awning Decked Vessels to have a maximum loadline marked. In 1874 the Royal Commission on Unseaworthy Ships dealt with the question of loadlines, and under the stimulus of Samuel Plimsoll three Merchant Shipping Acts were passed by parliament in 1874–75–76, which together brought the freeboard question to a definite position. (The sailor to-day regards the freeboard mark as the "Plimsoll" line.) These acts required the owners of foreign-going ships to mark the position of the upper deck line and to mark also a circular disc showing the maximum draught to which they claimed to load, while the distance between the deck line and the centre of the disc was recorded and inserted in the agreement with the crew.

While by the act of 1873 the Board of Trade were given power to detain overladen ships, yet without certain rules for guidance as to what constituted an overladen vessel the surveyors at the ports were in an impossible position. In order to remove these difficulties Benjamin Martell, the chief surveyor to Lloyd's Register, suggested in 1874 a series of tables of freeboard based on actual experience with British vessels. The Board of Trade in 1875 called a conference with Lloyd's Register which laid down as principles that—(i.) There should be an enclosed buoyant volume above water which should be a certain proportion of the volume of the ship below water; (ii.) There should be a certain height of the exposed deck at particular places (known as "height of platform") such as at the forecastle and bow, at the stern, and at the bridge or navigating position; (iii.) The construction of the vessel should be sufficiently strong, and all exposed openings in the main or weather deck should be properly closed.

The question of tables, based on these principles, was further examined by Lloyd's Register in 1882 and by the Board of Trade which appointed the first loadline committee in 1883. This committee drew up a set of tables which was adopted voluntarily in 1885 and made compulsory by the Merchant Shipping Acts of 1890. Authority was given by the Board of Trade to Lloyd's Register, the Bureau Veritas, and the British Corporation to fix the freeboards on behalf of the Government. The Rules and Tables drawn up in 1890 have served since that time as the basis of freeboard; they have been examined and adjusted on several occasions principally in 1898 and in 1906, in which latter year the Merchant Shipping Acts were amended to apply to all foreign vessels using British ports. In 1908 an arrangement was made with Germany to adjust the differences between the practice of the two nations. As a consequence those tables have not only remained in force but have been adopted by all the maritime countries.

In 1913 a further load line committee was appointed and reported in 1915, but the war delayed any action, and in 1927 another committee was asked to reconsider the whole problem, and in addition to examine (a) the practice of various countries which permitted vessels carrying wood cargoes to load deeper, and (b) the contention of the United States that oil tankers (vessels carrying entire cargoes of oil) could with safety be loaded deeper than ordinary ships. This committee is still sitting, and has before it a suggested departure in principle, viz.:—to allow vessels which carry whole cargoes of timber and oil to be loaded deeper than other ships.

The detailed calculations to ascertain the freeboard of a vessel are necessarily complex and can only be undertaken by an expert. In order however to give an idea of the actual amount of freeboard it may be taken roughly that for a cargo vessel having a forecastle, a bridge and a poop the freeboard will be about one quarter of the depth of the ship from the keel to the uppermost continuous deck.

(b) *Passenger Ships.*—The question of additional protection of passenger ships arose from a committee which in 1887 was considering the regulations for boats and life-saving appliances on British vessels; Thomas Gray, the official then in charge of the Marine Department of the Board of Trade, suggested that a proper arrangement of internal partitions ("bulkheads") should be provided in order that the vessel might remain afloat for a reasonable length of time to enable the life-saving appliances to be used. The Bulkhead Committee of 1890 suggested rules for the number and position of bulkheads, which permitted a reduction in the amount of life-saving appliances. The conclusions of this committee determined the practice until 1911, when the Merchant Shipping advisory committee suggested that the question of life-saving appliances needed adjustment. Following the loss of the "Titanic" in April 1912 a Bulkhead Committee was appointed to consider the whole question, but after the Court of Enquiry presided over

by Lord Mersey, the question of subdivision was separated from that of life-saving appliances. Consequently for the first time regulations were prepared for the number and position of bulkheads (subdivision). It was laid down that passenger vessels should have as efficient a scheme of subdivision as the nature of their service or their trade would allow. It was realized that regulations which destroyed the economic possibilities of trade were worse than useless.

While this committee was sitting an international conference was held in London to consider the whole question of safety of life at sea—embracing subdivision, life-saving appliances, wireless and navigation. The general lines of agreement were embodied in a convention signed by all the principal maritime nations (save Japan) in March 1914—and adopted by parliament in Great Britain and some other countries; but it was only made partially operative on account of the World War. As in certain respects the subdivision regulations were incomplete, the British Government only put into operation the minimum requirements and applied these to all passenger vessels which carried more than 12 passengers. When however during the war the provisions of the convention were examined in regard to new ships, it was rapidly found that such drastic alterations were required to vessels carrying a relatively small number of passengers as to render them economically impossible.

The whole question has been re-examined both by Governments and by the International Chamber of Shipping, and as a result the question of revising the whole convention was under consideration in 1928. It has been generally recognized that while the regulations laid down in 1913–14 might be deemed to apply to vessels almost wholly devoted to passengers, such as the large liners on the North Atlantic, yet considerable alterations are necessary to apply them to all other passenger ships.

Any system of subdivision must take into account—

(a) the spring of (*i.e.,* distance between) bulkheads—the more passengers carried the closer is the spacing;

(b) the height of the bulkheads above water—the greater the height, the wider is the spacing;

(c) the strength of the bulkheads in relation to the height of water which may be behind them when an adjacent space is full of water;

(d) the probable contents of the various parts of the vessel—some spaces requiring more water to fill them than others, and

(e) the nature of the damage to the side and underwater portion of the ship; it should be observed that it is of little use providing bulkheads unless the ship can remain afloat with the space between them open to the sea, and that where any greater protection is necessary endeavour should be made to arrange that the vessel will float with an intermediate bulkhead damaged and the space open to the sea.

Lloyd's Register of Shipping and the other classification societies have rules for the number of bulkheads in cargo vessels. A bulkhead is required near the bow called the collision bulkhead, one has to be fitted at each end of the machinery space, and another near the stern. In general, while all ships have 4 bulkheads, yet when the length exceeds 285 ft., more bulkheads are required on the scale of one bulkhead for about every 65 ft. increase in length; thus a vessel 285 ft. long should have 5 bulkheads, and one 610 ft. long 10 bulkheads. The result of the suggested amendments to the convention would be that with a small number of passengers there would be the same number of bulkheads as required by Lloyd's rules, but these bulkheads would have to be spaced in accordance with the principles given above. (W. S. A.)

SHIPPING: TONNAGE TERMS. The term "Tonnage" has a variety of meanings. According to the British Merchant Shipping acts and the Suez and Panama Canal regulations it is a measurement of the capacity or volume of a ship expressed in units of 100 cubic feet—one unit of such volume being termed a ton measurement. The purpose of measuring a ship is two-fold—primarily to form a basis for the payment of the various charges which are levied by Port and Harbour authorities, by Lighthouse Boards and for pilotage services; secondly for use in the registration or identification of the ship itself. (*See* SHIPPING: *Registration, Classification and State Regulation.*)

Tonnage legislation dates from very early times, not only in the Mediterranean but also in the Far East, where in China some form of measurement has existed since before the Christian era. The earliest known record in Great Britain occurs in A.D. 1422, which provides that "keels (barges) that carry coals at Newcastle shall be measured and marked." In 1694 the actual weight carried was recorded and was ascertained by placing known iron or lead weights on board, 20cwt. avoirdupois being taken as a ton. In France in 1681 the volume was measured approximately and expressed in tons of 42 cubic feet, on the assumption that 4 wine tuns—which average that particular volume—weighed 1 ton avoirdupois. There is thus from early times a considerable confusion of thought as to what is the real meaning of the word "ton," it being apparently connected both with the ton avoirdupois and with the tun of wine.

Methods of Measurement.—Besides the methods prescribed by the Merchant Shipping acts, which are generally followed by the principal maritime nations of the world, there are other methods used for various purposes. The principal methods may be summarised as follows:—

(1) *Measurement or Capacity Tonnage* (British Merchant Shipping Acts). (a) Under-deck tonnage, which is the total internal capacity of a ship below the tonnage deck. (b) Gross tonnage, which is the sum of the under-deck tonnage and of all enclosed spaces above the tonnage deck—there being, however, certain portions above the tonnage deck which may be exempted from measurement. (c) Register or net tonnage, which is derived from the gross tonnage by deducting the volumes of certain "non-earning" spaces—spaces which cannot, broadly speaking, be utilized for the carriage of cargo or passengers.

(2) *Displacement Tonnage.* This system is invariably used for warships, and represents the weight expressed in tons avoirdupois of the vessel when fully loaded. It is called displacement because it is generally ascertained by calculating the weight of the water displaced by the form of the vessel when immersed to the loadline.

(3) *Deadweight Tonnage.* Deadweight tonnage is the weight in tons avoirdupois of cargo, passengers, fuel and stores which can be carried by a vessel when fully loaded. It is the difference between the weight of a vessel (including machinery)—or what is termed the light ship—and the weight of the vessel and the contents when fully loaded.

(4) *Freight Tonnage.* Freight tonnage is a measure of the total cubic capacity of a vessel which is available for the carriage of cargo, and is usually expressed in tons of 40 cu.ft. measurement, it being assumed that 40 cu.ft. weigh 1 ton avoirdupois. Under the British system of tonnage measurement, the tonnage deck is the upper deck in vessels which have one or two decks, and in all other vessels it is the second continuous deck from below. The upper deck is the uppermost complete deck the openings of which are closed in such a way that any space below the deck is regarded as a closed-in space by the Board of Trade. The tonnage dimensions, *i.e.,* length, breadth and depth, differ from the *registered dimensions* (*see* SHIPPING: *Registration, Classification and State Regulation*)—although these are both ascertained at the same time by the surveyor who is measuring the tonnage.

For purposes of tonnage, the length is measured along the centre line of the upper surface of the tonnage deck from a point forward where the inner surface of the frames or lining crosses the deck at the bow to a similar point aft. The tonnage breadth is taken horizontally from face to face of the inside of the frames, or of the inside of the lining on the frames provided the lining is not more than 3 in. thick. The depth for tonnage in vessels with double bottoms is measured from the upper surface of the inner bottom plating at the centre line to the under side of the tonnage deck, from which is deducted one-third of the curvature or "round" of the deck beam, while a further deduction is made if a lining is fitted on the inner bottom.

For purposes of registration, the length is taken from the fore part of the bow, on the line of the forecastle deck, to the after side of the head of the sternpost (or the centre of the rudder stock where no sternpost exists). The breadth is the maximum breadth

measured to the outside of the plating of a steel ship, or to the outside of the planking of a wooden ship. The depth is measured from the top of the tonnage deck beam at the centre line amidships to the top of the inner bottom plating. In the measurement of tonnage, the area of cross section in the space under the tonnage deck is determined at a number of places—depending on the size of the ship, and from these areas—which are obtained by actual measurement at the ship—the volume of the under-deck tonnage is ascertained. The result in cubic feet divided by 100 gives the under-deck tonnage. The spaces above the tonnage deck are now measured, such spaces being either those which extend through a complete 'tween deck or those which are situated above the upper deck. All spaces which are deemed to be properly enclosed are required to be measured and included in the gross tonnage. Such spaces as hatchways have to be measured and their volume ascertained, and any excess over a certain amount is added to the tonnage. There are, however, certain spaces (such as shelter decks, forecastles, bridges or poops) which may be closed in certain defined ways, and which so long as they have the accepted methods of closing are not measured for tonnage nor included in the gross tonnage.

"Gross" and "Net."—From the gross tonnage—which is the sum of the under-deck tonnage and of the tonnage above the tonnage deck—the register or net tonnage is obtained by making certain deductions on account of the space in which the machinery or engines and boilers are situated, on account of crew spaces, and on account of certain small spaces necessary for the general working of the ship. The most important of these is the allowance for the machinery space; the other two items, although of importance, amounting to only some 10% of the total deductions permitted. The allowance for machinery spaces appears to be designed to include not only the volume actually occupied by the machinery itself, but also an allowance on account of the fuel necessary to propel the ship. The present allowance is based on the use of coal as a fuel and on the use of steam machinery. It is quite evident that the fuel space allowance must be the subject of compromise, since for the same ship the length of voyage may be very variable. It is usual to provide in all ships a certain amount of permanent bunker space, which may, for the average sea-going ship, be roughly described as that necessary for a month's voyage. The spaces occupied by the main machinery (including the necessary light and air spaces and shaft tunnels) are measured. The total deduction permitted is either $1\frac{3}{4}$ times the propelling space, or 32% of the gross tonnage where the actual measurement of the propelling space lies between 13% and 20% (both inclusive) of the gross tonnage. It will therefore appear that the difference between the volume of the machinery space and the volume allowed to be deducted represents the allowance made for the space deemed to be occupied by fuel. In order to take full advantage of this deduction, all low-powered steamships have the volume of machinery space so arranged that it is never less than 13% of the gross tonnage. The Merchant Shipping Act of 1907, however, limits the deduction which may be permitted for propelling power to a maximum of 55% of the gross tonnage. It must be recognized that with the improvement in marine engines and the adaption of the oil motor for propelling purposes, the tendency is for the machinery spaces to be less in volume than the 13% necessary for the ordinary marine steam machinery, and in this respect it will probably be necessary in the future to reconsider the allowance which may properly be made. The register or net tonnage is now determinable (being the gross tonnage less the deductions permitted as described above), and is the tonnage which appears on the register of the vessel and on which dues are assessed. The British system of measurement has been generally adopted by all the maritime nations, the principal differences in those which do not identically comply being on account of the method of estimating the propelling power deduction. It may be said that generally the tonnage as measured by any maritime country will not differ more than about 2% from that obtained by the British measurement.

Suez and Panama "Tons."—This satisfactory state of affairs does not, however, obtain with the Suez and Panama canal authorities, whose regulations differ from the British in giving less allowance for deductions, and in requiring more of the superstructures to be taken into the gross tonnage. Approximately it may be stated that the gross tonnage for the Suez Canal is 5% higher than the British, and that for the Panama Canal 10% higher, while the net tonnage for the Suez Canal is nearly 30% higher, and for the Panama Canal about 25% higher, than the British measurement.

It is difficult to express briefly the relation between tonnage and size of ship. As an example, an ordinary cargo steamer which can carry a nominal deadweight of about 8,000 tons avoirdupois of cargo, fuel and stores will have a displacement of about 11,500 tons, a gross tonnage of about 5,200, and a registered or net tonnage of about 3,200. The net tonnage is relatively highest in this type of steamer, where it may be as much as 65% of the gross tonnage. This figure is reduced to 50% for coasting cargo vessels of small size. In fast steamers, where a large proportion of the space is taken up by machinery, the net tonnage may be as low as 50% of the gross tonnage, and for such extreme types as the cross-channel boat the ratio may be as low as 40%.

SHIPPING, WAR CONTROL OF: *see* War Control of Shipping.

SHIPPING: WAR LOSSES OF. The outstanding features of the attack upon merchant shipping in the World War were (1) the enormous preponderance of the British losses, (2) a neutral nation—Norway—suffered the second largest losses, (3) two allied nations, the United States and Japan, owned more shipping at the end of the war than at the beginning, every other nation possessing less, (4) submarines accounted for 87% of the losses, (5) nearly one-half of the losses occurred in the 12 months Nov. 1916 to Oct. 1917, (6) marine losses of British ships were nearly 50% greater in 1918 than in 1913, (7) one commerce raider, "Möwe" accounted for more than double the number of ships sunk by any other individual surface craft, (8) on an average approximately 1,000,000 tons of shipping was continuously under repair, (9) the current losses were greater than the output of new shipping until the last nine months of the war.

The enemy conducted his campaign by submarine, by surface craft and by mine, five vessels only being sunk by aircraft. To losses directly due to enemy action must be added the losses due to marine risks which were greatly increased by strandings and collisions, resulting from the unlighted coasts, concentrated shipping, etc. There was also a diminution of effective tonnage on account of damage to vessels which ultimately reached port. The campaign falls into three periods, the first extending until Aug. 1916, when the enemy began an intensified effort. This continued until the "sink-at-sight" campaign began in Feb. 1917. For this last period, much more detailed information was obtained regarding the circumstances of each attack, and this part of the campaign can be studied from every possible standpoint. Comparison cannot be made, however, with the earlier periods owing to the lack of the earlier statistics, particularly in regard to foreign tonnage. In the case of British tonnage, the losses do not include merchant ships which were fitted out as armed escorts or as merchant cruisers for the protection of shipping routes, etc.

World's Losses.—Excluding tonnage owned by the then enemy countries, the world's losses by enemy action were 6,604 vessels aggregating 12,850,814 tons, or approximately one-third of the pre-war tonnage of the world. To this figure must be added the losses due to marine risks, approximately 2,102,000 tons, making a grand total of nearly 15,000,000 tons. The table at the top of the next page shows the losses suffered by each of the principal allies and by neutrals as the result of enemy action.

Excluding fishing vessels, the total war losses of the allies and neutrals were in part made good by new construction (10,849,000 tons) and by 2,411,000 tons captured from the enemy, the total

Number and Tonnage of Merchant and Fishing Vessels Sunk by Enemy Action, 1914–18

Country	Number				Tonnage			
	Periods			Total (51 months)	Periods			Total (51 months)
	24 months from 1. 8. 14	6 months from 1. 8. 16	21 months from 1. 2. 17		24 months from 1. 8. 14	6 months from 1. 8. 16	21 months from 1. 2. 17	
					Thousand tons			Tons

Totals (all countries other than enemy countries)	1,349	1,082	4,173	6,604	2,534	1,782	8,534	12,850,814

*Excludes and † includes 118 ships of 298,393 tons which when sunk belonged to countries which were neutral but subsequently became allies.

pre-war tonnage of 34,825,000 being reduced to 33,041,000 tons. There were net gains to the United States of 4,196,000 tons (128% over 1914) and to Japan of 677,000 tons (67%), while the largest net losses were to United Kingdom 3,084,000 tons (17%) and to Norway 1,260,000 tons (48%).

British Losses.—2,479 merchant vessels (7,759,090 tons) belonging to the United Kingdom and Colonies were sunk by the enemy, and of British fishing vessels 675 (71,765 tons). Submarines accounted for 2,099, the figures for the three periods being 342, 211 and 1,546, mines for 259 (102, 42, 115), surface craft for 117 (72, 18, 27) and aircraft 4 (three at the beginning of the "sink-at-sight" period).

Submarine Attacks During the Unrestricted Campaign.—During the 21 months, 3,672 vessels were reported attacked, of which 2,930 were by torpedo and 742 by gun-fire. Of those attacked, 2,262 were sunk, 345 damaged and 1,065 escaped. Of the 2,930 attacked by torpedo, 1,949 were British (28% escaped) and 981 foreign (18% escaped). Of the 742 attacked by gun-fire 368 were British (71% escaped) and 374 foreign (21% escaped).

A comparison between the 9 months Feb.–Oct. 1917 with the same period in 1918 gives the following interesting figures:—

Method of attack	British				Foreign			
	Attacked	Escaped	Sunk	Damaged	Attacked	Escaped	Sunk	Damaged
By torpedo,								
1917	958	253	615	90	533	80	419	34
1918	723	226	387	110	295	71	200	24
By gun-fire,								
1917	301	209	87	5	276	44	218	14
1918	48	35	12	1	72	28	39	5

Losses by Surface Craft.—Of the 191 vessels (562,900 tons) lost throughout the war, cruisers accounted for 48, raiders 61, armed merchant cruisers 27, and torpedo boats, etc. 55; 117 were British (averaging 3,800 tons) 43 allies (1,900 tons) and 31 neutrals (1,200 tons). The most successful enemy vessel was the raider "Möwe," which in the 15 months from Jan. 1916 sank 38 vessels (33 British). The cruisers Emden and Karlsruhe in the first four months of the war had 17 and 16 to their credit, all except one being British vessels averaging 4,000 tons. Two other raiders "Seeadler" and "Wolf" operating 2 and 6 months in 1917 accounted for 12 and 10, each sinking 6 British vessels. The armed merchantmen Kronprinz Wilhelm sank 9 British and 5 others and the Prinz Eitel Friedrich 5 British and 6 others, before being interned in March and Feb. 1915 respectively. The 16 British vessels sunk by torpedo boats and by unidentified vessels averaged 1,275 tons and the 39 others were about the same size.

Losses by Mine.—The chief centres in which mines were laid by the enemy were the East Coast and the English Channel. During the 21 months of unrestricted campaign, 119 vessels over 500 tons (of all countries) were lost, of which 88 were in home waters. There was a steady fall in losses after the first quarter, when 22 were lost in home waters and 8 in other areas. Nearly 10,000 mines were swept up in home waters. Usually the half-yearly yield by sweeping was between 1,000 and 1,350, but in 1917 the yields were 2,452 and 1,835. The improvement in dealing with new minefields is best indicated by the fact that the number of mines swept up was about 9 times the number of vessels struck in each of the half years up to June 1916, after which the proportion went up to 14, 16 and 23 times in the subsequent half years until it was 35 times in Jan. 1918.

Marine Losses.—The British tonnage lost during the war owing to marine risk was 1,100,000 tons, or rather more than half the world's losses from this cause. The next largest losses were those of the United States—302,000—and Norway 132,000 tons. During 1918 the British losses totalled 256,000 tons exclusive of 3,784,000 tons damaged. For allies and neutrals during the same period the figures were 330,000 sunk and 2,262,000 tons damaged. Detailed information relating to all tonnage lost by marine risks during the last 6 months of the war shows that of 191 vessels (368,000 tons) sunk, 54 were lost by collisions, 22 by fire or explosion, and 60 ran ashore. The remaining 55 foundered, capsized or were lost from unknown causes. Taking British vessels only, the pre-war monthly loss from marine risks was 18,000 tons, but during the war years it showed a continuous increase, namely, 21,000, 22,000, 24,000 and 26,000.

Damaged Tonnage.—It has been estimated that the quantity of shipping continuously out of service undergoing or waiting repair averaged 1,000,000 tons, half of which was damaged by enemy action and half by marine risk. The British and foreign tonnage damaged by enemy action during the 6 quarterly periods from Feb. 1917 varied between 253,000 tons and 378,000 tons; 80% of the total was British (1,550,000 tons), the rate of damage showing a marked decline during the later months of the war. The average time that this tonnage was out of service was 5 months. As regards shipping damaged by marine risks, the average monthly tonnage during the 10 months of 1918 was 378,000 tons of British and 226,000 of foreign vessels, but these figures include quite minor damage. Nearly 40% was due to collision and nearly 24% to machinery breakdown. About one-third of the casualties occurred in the English Channel and the East Coast.

The total tonnage of the monthly sailings of British vessels for overseas destinations other than near continental ports increased from about 5 million tons in 1917 to 6 million in 1918, while the percentage of losses fell from about 4½ in the first two quarters of the unrestricted campaign to 3 in the October quarter, 1½ in Jan. 1918, and to 1⅞, 1½ and 1% in April, July and Oct. 1918. Taking British and foreign vessels leaving U.K. ports for overseas destinations the tonnage of the sailings increased from 6½ million in April to nearly 8 million in Oct. 1918, and the percentage losses during 1918 were highest in the April quarter at

$1\frac{3}{4}\%$ and lowest in October at just over 1%.

Losses Under the Convoy System.—During the spring of 1917, the system of special routes for independent sailings was gradually superseded by that of convoy. In the French coal trade, which occupied nearly 38,000 sailings during the war with an average loss of only 0·14%, the losses during the heaviest period of the "sink-at-sight" campaign were 0·16%, while during 1918 they were reduced to 0·07%. The success of the convoys to Scandinavia was marred by two costly surface attacks, the percentage of losses being 1·16%, which was afterwards reduced to 0·39%. Overseas shipping that was convoyed increased from 2,700 vessels in April–Oct. 1917 to 7,700 for the same period in 1918, while the losses—including those by marine risks arising out of convoy conditions—fell from 1·01% to 0·66%. The grand total of vessels convoyed during the war under the British organization was nearly 90,000, the losses being 436 or approximately $\frac{1}{2}\%$.

Area of Operations.—During the unrestricted campaign, the area of the enemy operations may be divided into four main groups (1) the English coast, (2) the western approaches north and south of Ireland, (3) the South Atlantic from Land's End to the neighbourhood of the straits of Gibraltar, and (4) the Mediterranean. Round the English coast, the losses from enemy submarines showed little variation from the beginning of the campaign in Feb. 1917 until the blocking of Zeebrugge and Ostend in April 1918, when the losses fell from an average of 56 vessels per month to 28. The east coast section suffered heavily in June 1918 mainly in the north-east convoy when 21 vessels were lost as compared with an average otherwise of seven. The English Channel section was subjected to a burst of activity by the enemy in Dec. 1917 when the previous average of 22 vessels lost per month went up to 37, after which it fell to 23 and later to six. In the Irish Sea section, Feb. to April 1918 were bad months, the losses averaging 16 monthly compared with 5 and 4 per month respectively for the periods before and after that quarter. In the second group (western approaches), the fall in the monthly losses from 41 in the 6 months Feb. to July 1917 to 4 in the subsequent 6 months was attributable to the convoy system, as was also that in the third area (South Atlantic) from 26 to 16 per month. In the Mediterranean, the losses in the 6 months Feb. to July 1917 averaged 30 per month and in subsequent similar periods were 27, 21 and 11 vessels per month. The improvement was greater in the western Mediterranean than in the eastern.

Protective Measures.—Devices for the protection of individual ships included "paravane" and "otter" gear for use against mines, smoke apparatus for spreading a screen against the enemy and dazzle-painting, a colour scheme to create a confusional effect as to the vessel's course and speed. But the greatest protection lay always in the watchfulness and resource of the officers and men of the merchant service, undismayed by the fact that 62% of the vessels struck sank within 15 minutes. (H. W. G.)

SHIPPING: WRECK STATISTICS. About 1870, Samuel Plimsoll, a Member of Parliament, commenced an agitation against the overloading of ships and the sending to sea of unseaworthy ships. This agitation led to the appointment of a royal commission on unseaworthy ships. Important load-line legislation followed and the freeboard mark on British vessels is still known as the Plimsoll mark.

The 19th century was a period during which the British merchant marine was rapidly growing numerically and in which at the same time sail was being replaced at first gradually and then more rapidly by steam. The royal commission on unseaworthy ships, in the introductory paragraph of their preliminary report in Sept. 1873, drew attention to the danger of statistical comparisons of wrecks "because with the employment of steamers a greater number of voyages may be made with fewer vessels." In spite of considerable improvement in the quality and quantity of official statistics since Farrer's day, it is not yet possible to relate the number of wrecks to the number of voyages or the number of lives lost to the number of persons employed on such voyages and thus exposed to risk.

On the 31st Dec. 1829, there were 18,823 sailing vessels on the United Kingdom register aggregating 2,170,458 net tons. During that year, according to a parliamentary return, 1,305 sailing vessels of 98,894 net tons were wrecked. This is 6·9% of the number and 4·6% of the tonnage. Sailing vessels employed in the long distance trades made only one or two voyages a year, and the smaller vessels employed in the shorter trades were frequently laid up for the winter months. During the four years 1826 to 1829, 4,720 sailing vessels were totally lost or an average of 1,180 per year.

Safety through Steam.—Although 287 steam vessels of 29,501 net tons were already on the register in 1829 no record of losses of steam vessels appears to be given in the parliamentary papers of that year. The following table gives an imperfect indication of the increasing safety to the ship resulting from the substitution of sail by steam. It is of course an understatement as it makes no allowance for the fact that the distance travelled by the steam vessel in a year was three or four times greater than that travelled by the sailing vessel.

Period	Average number of vessels on the register		Average number of vessels totally lost or missing	
	Sail	Steam	Sail	Steam
1841–50	23,500	1,000	518	7
1851–60	25,200	1,600	570	17
1861–70	24,400	2,600	640	38
1871–80	21,600	4,200	640	80
1881–90	17,000	6,600	500	140
1891–1900	12,500	9,200	340	130
1901–10	9,900	10,500	230	110
1911–20*	7,600	12,200	110	120
1921†	6,300	12,700	49	142
1922	6,200	12,800	41	129
1923**	6,000	12,400	62	146
1924**	5,800	12,500	47	133
1925**	5,800	12,500	41	106
1926**	5,700	12,500	29	102

*Excluding losses of vessels by enemy action and losses of vessels due to mines. †Excluding losses due to mines. **Excluding vessels belonging to the Irish Free State.

The substitution of the intrinsically safer steam vessel for the sailing vessel has not only lowered the risk of loss to shipping as a whole but the loss among sailing vessels, as such few sailing vessels as remain are only very occasionally employed on the longer and more dangerous routes or at the more dangerous seasons.

The Hazards That Remain.—It remains true, however, that the occupation of the seaman is hazardous. That part of the Registrar General's decennial supplement for England and Wales 1921, dealing with occupational mortality, after pointing out the difficulty of preparing figures by which the mortality of seamen from all causes may be compared with the mortality of all occupied males, comes to the conclusion that the seaman's mortality from disease exceeds the average by 48.8% and his mortality from violence by 430%.

The loss of life among seamen and among passengers caused by wreck of or casualty to the vessel has, however, notably diminished in recent years.

The following table shows in five yearly periods the loss of life among passengers and members of the crew from these causes from 1871 to 1925.

*Lives Lost by Wrecks and Casualties at Sea to Vessels Belonging to the United Kingdom**

Averages for five year periods

Period	Passengers lost	Seamen lost
1871–5	406	1,943
1876–80	154	1,593
1881–85	136	2,053
1886–90	288	1,259
1891–95	429	1,356
1896–1900	157	966
1901–05	179	709
1906–10	102	636
1911–15	380	825
1916–20	187	385
1921–25	10	287

*From the Board of Trade *Reports of Shipping Casualties.*

During 1926 only two passengers lost their lives from casualties to vessels in which they were travelling. The corresponding numbers for 1925 and 1924 were four and five respectively. These figures are much smaller than those relating to the pre-war periods.

W. Verdier, Journal Royal Statistical Society (1922). (L. I.)

WRECK STATISTICS, UNITED STATES

The statistics of wrecks and casualties at sea occurring to vessels of the United States are useful for comparative purposes only since 1915. Before that time the figures reported by the United States Coast Guard regularly included disasters for foreign vessels on and near the American Coast.

Date year ended June 30	Number of vessels	Casualties involving partial and unknown damage	Vessels totally lost	Wrecks involving total loss	Vessels damaged
			Tons		Tons
1911–15	6,237	4,759	631,510	1,478	7,480,757
1916–20	5,000	3,391	958,571	1,609	7,433,821
1921–25	4,589	3,325	563,222	1,264	9,041,591

Date year ended June 30	Losses to vessels	Losses to cargoes	Passengers	Crews	Lives lost
	Dollars	Dollars			
1911–15	47,755,195	11,707,413	86,947	111,474	1,438
1916–20	197,202,420	69,017,135	49,445	98,667	3,255
1921–25	93,971,722	21,872,325	51,033	99,294	947

During 1926 there were 236 lives lost; number of vessels lost 982; wrecks involving total loss 254; casualties involving partial and unknown damage 728; vessels totally lost 93,539 tons; vessels damaged 2,015,068 tons; losses to vessels $15,596,857; losses to cargoes $4,324,475; 12,331 passengers and 21,970 crew. *See* reports of the United States Coast Guard, Treasury Department.

SHIPPING BOARD: *see* UNITED STATES SHIPPING BOARD.

SHIPPING CONTROL COMMITTEE. A co-ordinating body appointed by the British Government on Jan. 27, 1916, to decide on the allocation of British ships to essential requirements of Britain and the Allies, and to make representations to the Cabinet regarding ships required for naval and military purposes. (*See* WAR CONTROL OF SHIPPING.)

SHIPPING LINES AND GROUPS. The tendency for a large number of comparatively small shipowning firms to spring up during a period of prosperity and to collect into groups in the ensuing depression has long been one of the regular cycles of the shipping business. Since the latter part of the 19th century there has also been a general and increasing practice of combining big successful lines into huge groups.

British Empire.—Under the British flag the principal groups are the Kylsant, Inchcape, Furness Withy, Cunard and Ellerman amalgamations.

The group which takes its name from Lord Kylsant (Sir Owen Philipps) centres round the Royal Mail Steam Packet Co., which maintains services to South America, the West Indies and north Pacific. Numerous well known lines are associated with it. The Aberdeen Line runs to Australia and in 1928 absorbed the Australian State shipping service (Australian Commonwealth Line). The Shaw Savill and Albion Co. covers New Zealand, Elder Dempster and Co. (African S.S. Co., British and African S.N. Co., Elder Line and Imperial Direct Line) are principally concerned in the west African trade. On the various South American trades, in addition to the parent R.M.S.P., are the Lamport and Holt, Nelson and Pacific S.N. Lines, while the group is also interested in the Mihanovitch fleet of river steamers on the Plate. The King Line covers the general cargo trade; MacAndrews (including John Hall Jr. and Company) the Iberian business; the Glen and Shire Lines the Far East; the Moss S.S. Company the Mediterranean; the Union Castle Line East and South Africa; and Bullard King and Co. S. Africa and India. The White Star Line, purchased from the International Mercantile Marine in 1927 and bringing with it the Aberdeen and Shaw Savill businesses, is engaged on the American, Canadian and Australian trades. Numerous coastal, Irish Sea and Continental services are maintained by the Coast Lines (several small companies merged) and J. and P. Hutchinson. Among the group's interests outside shipping are Harland and Wolff and A. McMillan and Son the shipbuilders, and the London Maritime Investment Company.

The second big group is the Inchcape, at the head of which in 1928 was Lord Inchcape. The Peninsular and Oriental and British India Lines are the predominant partners, their interests being joined in 1914. Both are interested in the Indian, Eastern and Australian trades, the British India maintaining East African services in addition. The other companies connected with it include the P. and O. Branch Line (formerly Lund's Blue Anchor) and the Orient Line, both to Australia. The New Zealand Shipping Company, Federal Line, James Nourse, Hain Line, Union S.S. Company of New Zealand, Australasian United Line, General Steam Navigation Company, Khedivial Mail Line, Burns Philp and Company, the Eastern and Australian Line and Euphrates and Tigris S.N. Company are all closely connected. Nearly all these companies confine themselves to regular services but the General S.N. Company is largely employed on the coasting and continental trades and the Hain Line steamers are chartered all over the world. The group is also interested in shipbuilding on the Thames and Clyde and also in the English Channel.

The Furness Withy group was in 1928 under the control of Sir Frederick W. Lewis. It includes a large number of minor companies for agency purposes and otherwise, but also a number of important regular lines. In addition to Furness Withy and Company itself, running principally to Canada and the United States, there is the British and Argentine S.N. Company, the British Empire Steam Navigation Company, the British Transoceanic Line, the Furness-Houlder-Argentine Line, the Gulf Line, the Prince Line, the Johnston Line, the Neptune Line, the Rio Cape Line, the Warren Line, Manchester Liners, Messrs. Harris and Dixon, Houlder Bros. and Company, Norfolk and North American Steam Shipping Company, Bermuda and West Indies Steamship Company and the Danube S.N. Company. The group also controls the management of the Cairn Line to Canada. The organisation of the group is extremely complicated and units are constantly being transferred from one section to another. From being originally interested almost entirely in the North Atlantic trade, Furness Withy's activities extend nearly all over the globe and the firm possesses some of the finest cargo tonnage afloat. In addition to these shipowning concerns it has an interest in the British Maritime Trust, the Economic Insurance Company, the Queenstown Dry Dock Company, and the Blythswood Shipbuilding Company.

The Cunard group, under the chairmanship of Sir Thomas Royden, includes the various North Atlantic and Mediterranean services of the Cunard Line itself, the American-Levant Line (under the management of Messrs. S. and J. Thompson) the Anchor Line which runs on the North Atlantic and Indian services and which includes the old Donaldson Canadian service, the Brocklebank and Well Lines, and the Commonwealth and Dominion Line of big cargo liners which is interested in the Australian, New Zealand and South African trades as well as the American.

The Ellerman group, controlled by Sir John Ellerman, includes the Ellerman Line itself and the Bucknall, City, Papayanni, Hall and Wilson Lines, and Messrs. Westcott & Laurance. Its activities extend all over the globe, either by itself or in conjunction with other concerns and like the Furness Withy group has a very complicated organisation which constantly changes.

The Canadian Pacific Company has absorbed important concerns, such as the Elder Dempster company's Beaver service and

the Allan Line, but they have completely lost their identity. In addition to numerous services on the rivers, lakes and coasts of Canada it has both Transatlantic and Transpacific interests. Together with the Union Steamship Company of New Zealand (Inchcape group) it maintains the Canadian-Australian Line between Vancouver and Australia, alternative to the Suez route.

The Alfred Holt group, almost invariably known as the "Blue Funnel" from the characteristic appearance of its ships, consists principally of the Ocean and China Mutual Companies, with close connections with certain local companies in the East and shipbuilding concerns at home. Its ships are most familiar in the Oriental, East Indian, North Pacific, South African and Australian ports. The firm was one of the pioneers in fast cargo tonnage and still makes it one of the principal features of its policy.

The International Mercantile Marine has of recent years become more and more United States in character, although many of its ships still fly European flags. It was a combine formed by the late J. Pierpont Morgan in 1902 and its sale to the Kylsant group of the White Star Line did not break up the combine, although it took away the Shaw Savill and Albion and Aberdeen interests. There still remain the Leyland Line under the British flag, the Atlantic Transport Line, partly British and partly American, the Holland America Line and the Red Star Line on the North Atlantic and the Panama-Pacific Line and the International Mercantile Marine Corporation on the intercoastal trade. (F. C. Bo.)

The United States.—United States shipping may be divided into two broad groups: (1) domestic, including coastwise, intercoastal and Great Lakes shipping, and (2) foreign trade shipping. In the two groups there is a total of about 13,000,000 tons, and this is divided about equally.

In the domestic group some of the important companies engaged in shipping are the Panama Pacific Line, an International Mercantile Marine Company subsidiary; the Luckenbach Line; the Williams Line; the Munson-McCormick Line; and the Argonaut and Calmar Lines. The Atlantic, Gulf and West Indies Lines, commonly called the AGWI group, composed of the Clyde, Mallory, Ward and a few smaller concerns, is engaged partially in the domestic trade along the Atlantic Coast and partially in the foreign trade through its services to the West Indies and Central America.

In the foreign trade group, distinction may be made between privately owned lines and government owned lines. Through the Merchant Marine Act of 1920 the United States Shipping Board established 35 lines, five of which were passenger services, from American ports to the various ports of the world having commerce with the United States. There are no United States flag lines operated between two ports foreign to the United States. Sixteen of the lines established have been sold and are now operated privately by United States firms.

Among the larger American shipping concerns is the Dollar Steamship Line which operates passenger and cargo ships across the Pacific and also operates a fleet of seven passenger-cargo vessels in a round-the-world service. The bulk of the Dollar ships were purchased from the government. The Munson Steamship Line is the principal United States concern operating vessels from New York to the east coast of South America, while the Grace Line operates lines from both Atlantic and Pacific coasts of the United States to the west coast of South America. These two services carry both passengers and cargoes.

Of the strictly cargo services, the largest private line is the American Export Lines which runs from North Atlantic ports of the United States to ports of the Mediterranean and Black Sea. Others are: The American West African Line, the American South African Line, the Pacific Argentine Brazil Line operated out of San Francisco to the east coast of South America, the Oregon Oriental Mail which runs from Portland, Oregon, to the Orient, and the Tacoma Oriental Line which runs from Tacoma, Washington, to the Orient.

A large group which also has interests in the domestic trade is formed by the American Hawaiian Line and Matson Navigation Company. This group maintains passenger and cargo services from Pacific coast ports to the Hawaiian islands and cargo services from these American ports to Australia, Philippine Islands and the Orient.

The shipping board cargo lines are operated for the government's account through private shipping agencies, known as managing operators. These companies act as agents in the securing of cargoes and general management of the ships.

The one remaining government passenger line, the United States Lines, is operated direct by the United States Shipping Board Merchant Fleet Corporation which is the shipping board's business corporation. This line is operated in the North Atlantic between New York, Southampton, Cherbourg and Bremen.

In United States shipping it should also be noted that there is a large volume of tonnage coming under the class of so-called industrial carriers. The Standard Oil Company, the United States Steel Corporation, the United Fruit Company and the Ford Motor Company all maintain substantial fleets primarily for the transportation of their own traffic. (T. V. O'C.)

Other Countries.—There are also several groups on the Continent, particularly in Germany and France. In the latter country the Compagnie Générale Transatlantique, is intimately associated with the Fabre Line, the Chargeurs Réunis, the Compagnie Sud Atlantique, the Transports Maritimes Line and the Fraissinet Company. This group shows every indication of further extensions. In 1928 the Compagnie Générale Transatlantique, the Sud Atlantique, and the Chargeurs Réunis formed a company known as the Union Française d'Armement, to deal with matters concerning the interests of the three lines, fuel, victualling, agencies, and the like.

In Germany the policy of amalgamation has produced the keenest rivalry between the two big concerns, the Hamburg American Line and the Norddeutscher Lloyd, who between them own the greater part of the tonnage under the national flag. The latter includes the Argo Line, the Roland Line, the Horn Line, the Hamburg-Bremen-Afrika Line, the Seefahrt Co., the Hanseatic Co., and the Hansa Line, in addition to smaller concerns. The group also owns shipbuilding interests and in partnership with the Hamburg American Line has interests in the Deutsche Levante Line, the Deutsche Ost Afrika Line and the Woermann Line.

In addition to these concerns in which they share an interest with the Norddeutscher Lloyd, the Hamburg American group has the Deutsche-Australische, Kosmos and Hugo Stinnes Companies, also the Hamburg South American Line.

The big Italian group is headed by the Cosulich Line and includes the Lloyd Triestino, which before the war was the Austrian Lloyd, the Adria Line, the Marittima Italiana, the San Marco and the Puglia Lines, with other less important connections and considerable shipbuilding interests. There is also very close working between the various companies under State guidance quite apart from actual amalgamation. In northern Europe the principal groups are the Dan Brostrom group in Sweden, and the Forenede group in Denmark.

The Japanese companies have followed the policy of total absorption more than amalgamation, the two principal concerns being the Nippon Yusen Kaisha and the Osaka Shosen Kaisha. Both maintain a network of services all over the globe.

The tendency towards amalgamation in shipping appears to increase rather than decrease, particularly in periods of shipping depression. Compared with the huge groups mentioned, the independent shipping firms appear small, although there are many important ones still in service. Under the British flag the most important are the Clan Line of cargo ships, Messrs. T. and J. Harrison, Andrew Weir's Bank Line, the Bibby Line, Runciman's and Reardon Smith's, while some of the tanker companies also aggregate a big tonnage.

In France there is the Messageries Maritimes, in Italy the Navigazione Generale Italiana, in Spain the Compania Transatlantica, in the United States such concerns as the Dollar and Matson Lines, in Holland the Rotterdam Lloyd and Nederland companies, and in Denmark the East Asiatic Co., although the last-named has Swedish connections. (F. C. Bo.)

SHIPPING ROUTES. Regular shipping routes have existed as long as regular shipping, originally as measures of safety but afterward as part of the intricate organisation of trade. For this reason they are constantly changing with changed trade and political conditions.

Early History.—In the older history of shipping routes several factors must be especially considered. One of these concerns the relatively small size of the vessels used; it often made coastwise routes advisable and it permitted far more river navigation than can be accomplished by the deep-sea ships of to-day. Another factor was the discovery or introduction of the compass, probably in the 13th century. By means of it methodical charting was made possible, supplanting the accident-and-report system of the earliest times. It must be said, however, that such early route-maps as the *Periplus maris erythraei,* of the 1st century, show an attentive study and systematic record of what had been discovered by the use of the old method.

There were two other factors of the highest importance for the history of sea routes to the Orient. One was the discovery of the Indian ocean trade wind, which occurred, so far as Europe is concerned, at a time not far distant from the composition of the *Periplus.* As the story has come down to us, a marine tax collector in the Roman service was carried out into the Indian ocean by a high wind which maintained its direction steadily for many days. At the end of this adventure he was able to drop anchor in a port which proved to be in Ceylon. There he was made to understand that the wind set in alternate directions every six months and that he would be able to return to the Red sea after a certain interval and by the same means that had brought him out. This he did, with the result that the direct overseas route to India was often followed thereafter instead of the coastal one. However, as late as the 14th century, the Persian mariners still used the old route; they feared the long course because of the frail construction of their vessels.

In still earlier times there existed a navigable channel from the Nile to the Red sea—one which was silted up long before the end of the ancient period. Early shipping routes were thus strikingly influenced by accident as well as by discovery, and in no other field of endeavour has progress been more uneven.

Although the coastal and island navigation of the remotest times was never discontinued in the Mediterranean, the Roman empire developed several important long routes. A notable one was that followed by the grain ships from Egypt, which, generally setting out from Alexandria, rounded Crete and the southern coast of Greece and thence made a run due westerly to the straits of Messina, after which the course was northwesterly to Ostia, where the grain was unloaded for Rome. The most dangerous part of this route, incidentally, seems to have been at the entrance to the harbour of Ostia. Another route was almost due south from Ostia, between Corsica and Sardinia, then north of the Balearic islands and then southwesterly along the Spanish coast to the Strait of Gibraltar.

In the middle ages the main shipping routes substituted Venice and Genoa for Rome as their Italian termini, while Alexandria maintained much of its ancient importance. This was lessened, however, by the use of Constantinople as the gate to Asia Minor and the Far East and by the centralization of the eastern Mediterranean trade, for a considerable period, in Famagosta, on the island of Cyprus.

As was only natural before the science of navigation was developed, the first regular trade routes were coasting, giving some element of safety both from weather and enemy. The Mediterranean was crossed and recrossed by regular lanes at a very early date, then the Baltic and Atlantic coast of Europe, while they existed from the East African coast, Red sea and Persian gulf to India from time immemorial. The Portuguese found this trade fully organised and flourishing when they entered the Indian Ocean in 1498. Even later than that, the overland route developed by the Italian republics prospered, the sea portion being generally from Constantinople to Western Europe. Antwerp was one of the principal *entrepôts* for this trade.

One of the first long sea routes to be developed by European shipping was the "Guinea trade" to the west coast of Africa, which followed the ships of the fifteenth century explorers who were attempting to find a sea route to India. With the establishment of the regular slave trade this grew into a triangular route such as ship-owners frequently have to adopt in order to get the return cargoes which are an economic necessity. The regular run for British ships for nearly two centuries was out to the west coast of Africa with a general cargo of "notions," across to the West Indies with slaves, and home with sugar and rum. With certain changes due to the fluctuating slave market this triangle continued until the abolition of slavery.

The Portuguese were able to keep their secrets of the Indian trade for nearly a hundred years, but when it was opened to the English in the early 17th century, first to the islands and then to the mainland, this route was rapidly developed with a very necessary victualling station at the Cape of Good Hope. It was afterwards continued to China and when the East India Company lost its Indian monopoly in 1814 an alternative was found and it sent many of its ships to Australia with settlers and their stores, then on to China in ballast to load tea for Great Britain.

This tea trade attracted the attention of the American shipowners who, employing very much faster ships than the East Indiamen, worked up a big trade from the United States to China by way of the Cape with general cargo, collecting for the American and European markets. Their ships entered the British trade from China on the repeal of the Navigation Act, and for a time obtained the cream of the business but almost immediately afterwards the discovery of gold in California gave them such opportunity on a route that was protected from foreign competition that the Oriental trade was speedily abandoned.

This superior speed was characteristic of American ships. In colonial days their shipping was very severely handicapped by legislation, but as soon as the United States attained full independence they established a lucrative trade along a regular lane from the New England States to the West Indian islands, particularly with the Spanish possessions from which they were debarred. It was to avoid the Spanish warships that the American shipbuilders first turned their attention to speed, and it had a very considerable influence on their trading operations.

The direct route across the Atlantic from Britain to the United States was comparatively neglected until the end of the Napoleonic Wars, when the first of the fast sailing vessels which were to become famous as the Western Ocean Packets were started by enterprising Americans and soon included some of the finest ships afloat. Even when regular steamers were running the sailing packets maintained a large measure of their position, particularly in the emigrant traffic. The short distance and the big volume of passenger trade on the North Atlantic permitted fast and luxurious tonnage then just as it does to-day.

In the earlier days of Atlantic steam navigation the coal difficulty necessitated a call at Halifax, which was abandoned when more economical machinery was evolved. Although the direct service is more than ever important, the post-war tendency is to revive such intermediate calls with the less expensive tonnage, while the biggest ships tap the Continental as well as the British trade by making use of the various Channel ports instead of the Western.

The "Suez" Changes.—On the Eastern routes, the experiment of sending steam ships out to India by way of the Cape having proved too expensive to be practical, a new "overland route" was established in which a proportion of the tonnage was kept in the Indian Ocean, running from Suez, while other steamers carried the passengers and cargo to Alexandria, the connection across the Isthmus of Suez being made by caravan. The expense, trouble and discomfort of this route gave to the sailing ships which succeeded the East Indiamen, particularly the "Blackwall frigates," the greater part of the cargo and a proportion of the passenger business to India, Australia and the East until the Suez canal was completed in 1869.

This waterway changed all the principal trade lanes to the East. It was not suitable for sailing vessels but favoured the steamship in every respect, so that sailing ship freights fell and it became

necessary to build tonnage for large capacity rather than for small cargoes at high charges. This sounded the death knell of the clipper. Within comparatively few years the sailing ship as a first class passenger carrier was doomed, although it still had good chances of profit from emigrants and special passengers.

In the last quarter of the 19th century the west-about route to the Orient, New Zealand and Australia came into favour, the lines running across the Pacific from the Canadian and American ports in conjunction with the regular Atlantic services and trans-Continental railways. These routes are becoming more and more popular as an alternative to Suez and the trying passage of the Red sea, while their establishment has done much to encourage the regular trans-Pacific services which are now numerous.

When the business of sailing vessels on the Australian trade became more or less confined to the less expensive cargoes a new triangle was evolved in addition to the regular out-and-home run of the wool ships. This was from Europe to Australia by way of the Cape with general cargo, on to the West coast of South America with coal, and home with nitrates. Another triangle which existed for some years was out to the Cape with general cargo, railway materials or machinery, on to India in ballast and home with jute. Direct trades during the last years of sail were numerous, one of the most important being the grain trade from California which was finally covered almost entirely by subsidised Continental sailing ships able to do the outward voyage in ballast and still show a profit.

Meanwhile the tramp steamship route in the Mediterranean also tended to form a triangle—out to Italy with coal, then to the Black sea in ballast and back with grain. This route has been checked by the Russian revolution. Direct routes which absorbed and absorb much tramp tonnage are with coal out to the River Plate and home with grain and to the St. Lawrence, generally in ballast, for wheat. A certain number of sailing ships, nearly all owned on the Continent, still contrive to secure charters for Australian grain from the steamers.

The West African trade is now almost entirely direct, but in the case of South Africa the direct mail services are supplemented by intermediate services which reach the various East African ports by way of the Mediterranean and Suez, then proceed to the Cape and return direct to Europe by way of the West Coast.

As regards the Continental trades, the opening of the Suez canal permitted a rapid development of the routes from the Mediterranean to the East. The French, backed by the maritime interest of Napoleon III., and the Austrians took immediate advantage of it: the Spaniards and the Italians followed later. Of these the French and Austrians tended to keep their steam tonnage on the regular routes, leaving the tramp business to the sailing ships under their flags and to the steamers of their rivals.

The development of German shipping was slower. Despite the maritime heritage of the Hanseatic League it suffered from initial discouragement, largely on account of the fear held by the authorities that passenger communications would drain the country of conscripts. In spite of this discouragement steamship companies were formed both in Hamburg and Bremen in the mid-19th century, principally for the transatlantic trade. The policy was reversed by Bismarck in 1885, when he offered a heavy subsidy for German mail services, particularly to Africa, Australia and the East. German owners had always kept the greater part of their tonnage on regular routes, never favouring the tramping business.

Although the Italians were slow in starting on a large scale on the regular services, they have made great strides of recent years. Before the war they did a very extensive North Atlantic steerage business, but that was ruined by the restriction of U.S. immigration and many of the North and South American services have been combined to make the most of the seasonal trades. At the same time the Italians have adopted a very strongly protective policy to preserve for Italian ships their emigration, both across the Atlantic and to Australia.

In the West, until the latter part of the 19th century, it was quite usual for travellers from the United States to South America to travel by way of Europe, to the detriment of American trade, but there are a number of passenger companies now maintaining a direct service and a very big trade is done in addition to the passenger business.

Panama Changes.—The latest great influence on the trade lanes is the cutting of the Panama canal. It has provided very much shorter alternative routes from Europe to the whole of the Pacific seaboard, the saving in time in almost every case more than compensating for the canal charges and the sometimes vexatious regulations. It has also permitted the establishment of a new intercoastal trade between the Eastern and the Western States in opposition to the railways, reviving the old clipper route to California round the Horn. Being technically a coasting service, this is reserved for American ships and is attaining very large proportions.

The canal has also permitted the recent development of round-the-world cargo services, from the North Pacific ports to the Orient, through the East Indies to India, to New York via Suez and then back to the North Pacific ports along the usual intercoastal route. (F. C. Bo.)

SHIPS' FIGUREHEADS. The primitive ship was double-ended, with both stems, that is the stem and stern-post, rising above the planking of the hull; and nearly all types occurring from the earliest times till late in the middle ages are recognizable as variants of this original. The high stems were commonly so conspicuous as to be naturally the first parts chosen for decoration; and if only one of the two was decorated, that one was in most cases the stem. These stem-head carvings represent the earliest figureheads. When, as in the oared war-galleys of ancient Greece and Rome, the stem-head ceased to be conspicuous, a wood carving or bronze casting was fixed as near to the traditional position as was convenient, so resembling the modern figureheads in northern Europe. The few Roman figureheads which have survived from the period of the early empire are, save for their greater artistic merit, curiously similar to those which were applied to English men-of-war in the Napoleonic era.

Figureheads might be religious emblems, they might indicate the nationality of the ship, or might symbolize her name. Also as, with few exceptions, they represented living creatures, and as they are rarely if ever, in early times, found in conjunction with the oculus, it would seem that the mariner must have held, if only as a secondary consideration, that they helped the ship to find her way. The Phoenicians placed a horse's head on the fore stem, just as the English and the Dutch of the 17th and 18th centuries employed their national lions as figureheads; the Egyptians used various religious emblems, which probably served also to designate individual ships, as did the figures of the holy family and of saints in the Spanish navy in the 18th century; the Romans of the empire would seem to have named at least some of their ships after distinguished warriors, whose busts were employed as figureheads, in this anticipating the practice which began in England in the 17th century and became increasingly common from the middle of the 18th century onwards.

When, about the 13th century, the temporary fighting stages developed into integral parts of the hull, figureheads almost vanished for a long period; for the forecastle overlapped the stem-head, and left no very obvious position in which a figure could be carried. A very small carving on the foremost part of the rail of the forecastle itself, or a device placed under it across the stem, were the available alternatives, but both were quite ineffective. They served, however, to keep the tradition of the figurehead alive while this old type of forecastle, often nowadays spoken of as the "carrack forecastle," was universal in great ships. But in Henry VIII.'s reign the important change began which substituted the galleon type of ship for the carrack type. The galleon, as one of her most conspicuous differences from the old type, had the forecastle cut back so that it ended abaft the stem. The figure might therefore have resumed its old place on the stem-head, had not the introduction of the beak-head afforded a still better position for it. By the end of the 16th century the galleon type was universal, and the foremost end of the beak-head bore the figure. The beak-head altered its shape continually, but as the "head" it outlived the galleon and is found in the sailing man-of-war right

down to the days of steam; it always bore the figure at its fore end in men-of-war and in all merchantmen of similar build, the figure varying in size and general form to match with the changes of the head itself.

It will be enough to indicate what were the fashions in the figure itself in England from Elizabeth's reign onwards, for in no other country was the figure developed to a greater extent. At first a simple "beast" sufficed, being most commonly the lion or the dragon, the supporters of the royal arms. When the dragon was discontinued as a supporter, he ceased also to be used as a figure, and the lion during the 17th century was by far the most common figure. For great ships more elaborate figures were used, small groups, especially St. George and the dragon, which, though given always to ships bearing the name of St. George, was considered also as a national emblem. So too was a figure of Neptune. From Charles I.'s time also equestrian figures began to be used in the largest ships, and these in the 18th century developed to a portentous extent into the so-called "double" heads. From 1703 to 1727 the lion was established by order as the universal figure for men-of-war, but a dispensing order was nearly always forthcoming for the greatest ships. After 1727 any figure was allowed to be used which did not exceed the lion in cost; but in 1796 an attempt was made to abolish figureheads as an unnecessary extravagance. This order at once became a dead letter, and instead of it another was issued which cut down the cost to so low a figure that no more than "devices" could be given to the great ships, and busts to the smaller. One of these "devices" survives as the existing figurehead of the Victory. After 1815 busts continued, but grew greatly in size and about 1840 developed into half length figures of vast dimensions.

When, with the coming of steam, the old form of head fell out of use, the figure also became obsolete; but an attempt was made for several years to provide some sort of a substitute which usually took the form of a badge or scutcheon on each side of the stem. The last ships in the Navy to have figureheads were the sloops of the Odin class, which, indeed, served with them in the World War of 1914.

See L. G. Carr Laughton, *Old Ship Figureheads and Sterns*, illustrated by Cecil King, R.I. (L. G. C. L.)

SHIPTON, MOTHER, a reputed witch and prophetess who is supposed to have lived in early Tudor times. There is no really trustworthy evidence of her existence, but tradition has it that her maiden-name was Ursula Southill, Sowthiel or Southiel, and her parents were peasants, living near the Dropping Well, Knaresborough, Yorkshire, and that she was born about 1486–1488. Her mother, Agatha Southill, was a reputed witch, and Ursula, who was phenomenally ugly, was regarded by the neighbours as "the Devil's child." When about twenty-four she married a builder of York, Tobias Shipton. Her most sensational prophecies had to do with Cardinal Wolsey, the duke of Suffolk, Lord Percy and other men prominent at the court of Henry VIII. She is said to have died at Clifton, Yorkshire, in 1561, and was buried there or at Shipton. Her whole history rests on the flimsiest authority, but her alleged prophecies had an extraordinary hold on the popular imagination. The suggestion that Mother Shipton had foretold the end of the world in 1881 caused most poignant alarm in rural England in that year, the people deserting their houses, and spending the night in prayer in the fields, churches and chapels. This latter alleged prophecy was one of a series of forgeries to which Charles Hindley, who reprinted in 1862 a garbled version of Richard Head's *Life*, confessed in 1873.

See Richard Head, *Life and Death of Mother Shipton* (London, 1684); *Life, Death and the whole of the Wonderful Prophecies of Mother Shipton, the Northern Prophetess* (Leeds, 1869); W. H. Harrison, *Mother Shipton investigated* (1881); *Journ. of Brit. Archaeo. Assoc.* xix. 308. *Mother Shipton's and Nixon's Prophecies*, with an introduction by S. Baker (1797).

SHIR: *see* Bari.

SHIRAZ, the capital of the province of Fars in Persia, in 29° 38′ N., 52° 40′ E., 530 m. by road from Tehran and 180 m. N.E., by E. of Bushire (112 m. crowfly). The city stands 5,200 ft. above sea level on the right bank of a small stream, in a well watered plain about 7 m. wide, surrounded by mountains which on the west attain 11,000 ft. It is approached on the north through chains of hills which separate the plain of Mervdasht, where are the ruins of Persepolis; and on the south from the Persian gulf through difficult mountain passes, the highest of which attain 7,400 ft. The city is irregularly circular in plan and has a mud wall flanked by semi-circular towers, about 4 m. in circuit, but the suburbs have extended far beyond the enceinte. There are six gates and the town within the walls is divided into eleven quarters, one of which, the Mehalleh Yahudi, is inhabited exclusively by Jews numbering 2,200. The population has been very variously estimated: at 53,600 in 1884, 38,000 in 1900, and at 60,000 in 1904; no exact figures of more recent date are available.

Shiraz can make no claim to eminence by reason of its great antiquity. The general location is certainly ancient, as evidenced by the Achaemenian and Sasanian ruins in the vicinity—at Persepolis (some 45 m. N.E.) and elsewhere; but according to Mohammedan authors the town arose only after the Mohammedan conquest. Shiraz owes most of its architectural distinction to Karim Khan Zand (1751–79) who governed it as regent under the Safavid dynasty and made it his capital; but much of his work was destroyed by the eunuch ruler Agha Mohammed Khan, who razed to the ground the stone ramparts and replaced them by the existing mud wall.

Of its fifty considerable mosques, the Jami Atiq is amongst the most noted and ancient. The largest mosque, not only in Shiraz but in all Persia, is the Masjid i Nau, or New Mosque, built by Atabeg Sa'd bin Zangi, *c.* 1200, a building reconstructed out of his own palace; while perhaps the most beautiful is the Jami i Vakil of Kerim Khan built about A.D. 1766.

The gardens (*bagh*) and rose-bowers of Shiraz and its outskirts are famous and some of these pleasure-grounds, despite neglect, retain much of their original beauty. Close to the Bagh i Dilgushi, one of the most conspicuous of these gardens, north of the city, is the Sa'diyyeh, an enclosure planted with cyprus and orange trees which holds the tomb of the celebrated mystic poet Sa'di; and in a cemetery nearby is the Hafiziyyeh with the tomb of the poet Hafiz, a sarcophagus of Yezd marble on which two of the poet's odes are chiselled in relief. The true renown of Shiraz rests largely on the fame of these her two great sons and on other distinguished men she has given to Iran. It was also the birthplace of the religious reformer called the Bab.

Shiraz is an important trade centre and point of departure of passable motor roads: north, via Isfahan and Qum, to Tehran; north-east to Yezd; east to Kerman; and south-west to Bushire. The most noted product is wine of the Khullar vineyards, 30 m. N.W. of which, however, only a small quantity is exported, religious scruples preventing its production on a large scale. The town is noted for its silver-work, and it manufactures mosaics called *Khatam-Kari*, cloths, brocades and silk-floss, and is the centre of a rug industry. The climate though healthy is subject to extremes; the absolute maximum observed over a number of years was 113° Fahr. and the absolute minimum 21°. The town was laid in ruins by the earthquakes of 1813, 1824 and 1853, which also caused great loss of life.

See G. N. Curzon, *Persia and the Persian Question* (1892); E. G. Browne, *A year among the Persians* (1893 and 1926); A. V. Williams Jackson, *Persia past and present* (1906). (P. Z. C.)

SHIRÉ, a river of East Central Africa, the only tributary of the Zambezi navigable from the sea. The Shiré (length about 370 m.) issues from the southernmost point of Lake Nyasa and almost immediately enters a shallow sheet of water called Malombe or Pa-Malombe, 18 m. broad, and 12 or 13 m. long. A shifting bar of sand obstructs the end of Malombe nearest Nyasa, but does not prevent navigation. Below Malombe the bed of the Shiré deepens. The river flows through a mountainous country, and in its descent to the Zambezi valley forms rapids and cataracts, rendering its middle course for a distance of 60 m. unnavigable. The most southern and the finest of these cataracts is called the Murchison Cataract or Falls, after Sir Roderick Murchison, the geologist, who identified himself during the mid-Victorian epoch with geographical exploration in Africa. In

passing the cataracts the Shiré falls 1,200 ft. From the station called Katunga, a short distance below the cataracts, shallow-draught steamers can navigate the river when in flood (January-March) to its junction with the Zambezi, and thence proceed to the Chinde mouth of the main stream. The scenery of the lower Shiré is very picturesque, the spurs of the plateau forming bold, rocky crags overhanging the water. The river is studded with small islands usually covered by thick grass. A little before the Zambezi is reached the country becomes flat. The Shiré joins the main river in about 35° 25′ E., 17° 50′ S., at a point where the Zambezi is of great width and presents in the dry season many narrow winding channels, not more than 3 ft. deep, with intervening sandbanks.

The lower part of the Shiré is in Portuguese territory; the upper part is in the British Nyasaland Protectorate, to which it is the natural highway. Below Port Herald the Shiré is navigable all the year round.

(*See* Zambezi and British Central Africa.)

SHIRE, one of the larger administrative divisions in Great Britain, now generally synonymous with "county" (*q.v.*), but the word is still used of smaller districts. The Anglo-Saxon shire was an administrative division next above the hundred and was presided over by the ealdorman and the sheriff (*q.v.*).

SHIRE MOOT, an assembly of the free men of a shire for judicial, fiscal, and other administrative business. It is first mentioned in the reign of Edgar (958–975), and then probably consisted of all the free landholders of the shire. In course of time the burden of suit to this court became attached to particular estates, and by the 13th century the number of persons present at a shire court was small. Each shire moot met at a specified place, and in the 10th century twice a year only, though more frequent sessions were held in later centuries. The shire court received fresh importance in the 12th century from the occasional presence of royal justices itinerant, and at a later time it came to play an important part in the machinery by which members were elected to parliament from the counties.

SHIRLEY or **SHERLEY, SIR ANTHONY** (1565–*c.* 1635), English traveller, was the second son of Sir Thomas Shirley (1542–1612), of Wiston, Sussex. Educated at Oxford, he gained some military experience with the English troops in the Netherlands and also during an expedition to Normandy in 1591 under Robert Devereux, earl of Essex; about this time he was knighted by Henry IV. of France, which brought upon him Elizabeth's displeasure and a short imprisonment. In 1596 he conducted a predatory expedition along the western coast of Africa and across to Central America, but owing to a mutiny he returned to London in 1597. In 1598 he led a few English volunteers to Italy to take part in a dispute over the possession of Ferrara; this, however, had been accommodated when he reached Venice, and he decided to journey to Persia to promote trade between England and Persia and to stir up the Persians against the Turks. He was well received by the shah, Abbas the Great, who made him a *mirza,* or prince, and granted certain rights to all Christian merchants. Then, as the shah's representative, he visited Moscow, Prague, Rome and other cities, but the English Government would not allow him to return to his own country. For some time he was in prison in Venice, and in 1605 he went to Prague and was sent by the emperor Rudolph II. on a mission to Morocco; afterwards he went to Lisbon and to Madrid. The king of Spain appointed him to command an expedition in the Levant, which failed. After this he was deprived of his command. Shirley, who was a count of the Holy Roman empire, died at Madrid some time after 1635. His brothers Thomas (1564–*c.* 1620) and Robert (*c.* 1581–1628) were also great travellers.

Sir Anthony Shirley wrote: *Sir Anthony Sherley: his Relation of his Travels into Persia* (1613), the original manuscript of which is in the Bodleian library at Oxford. There are in existence five or more accounts of Shirley's adventures in Persia, and the account of his expedition in 1596 is published in R. Hakluyt's *Voyages and Discoveries* (1809–12). *See* also *The Three Brothers; Travels and Adventures of Sir Anthony, Sir Robert and Sir Thomas Sherley in Persia, Russia, Turkey and Spain* (1825); E. P. Shirley, *The Sherley Brothers* (1848), and the same writer's *Stemmata Shirleiana* (1841, again 1873).

SHIRLEY or **SHERLEY, JAMES** (1596–1666), English dramatist, was born in London in September 1596. His career of playwriting extended from 1625 to the suppression of stage plays by parliament in 1642. He was educated at Merchant Taylors' school, St. John's College, Oxford, and Catherine Hall, Cambridge, where he took his B.A. degree in or before 1618. His first poem, *Echo, or the Unfortunate Lovers* (of which no copy is known, but which is probably the same as *Narcissus* of 1646), was published in 1618. He took orders and held a living near St. Albans, which he left on his conversion to Catholicism. He was then (1623–25) master of St. Albans grammar school. Shirley settled at Gray's Inn, London, in 1625, and for eighteen years was a prolific writer for the stage, producing more than thirty regular plays, tragedies and comedies, and showing no sign of exhaustion when a stop was put to his occupation by the Puritan edict of 1642. Between 1636 and 1640 Shirley went to Ireland, under the patronage apparently of earl of Kildare, and three or four of his plays were produced in Dublin. On the outbreak of war he seems to have served with the earl of Newcastle, but soon returned to London. He supported himself chiefly by teaching, publishing some educational works under the Commonwealth. Besides these he published during the period of dramatic eclipse four small volumes of poems and plays, in 1646, 1653, 1655 and 1659. Wood says that he and his second wife died of fright and exposure after the great fire, and were buried at St. Giles's-in-the-Fields on Oct. 29, 1666.

Shirley constructed his own plots out of the abundance of materials that had been accumulated during thirty years of unexampled dramatic activity. He worked with confident ease and buoyant copiousness on the familiar lines, contriving situations and exhibiting characters after types whose effectiveness on the stage had been proved by ample experience. His scenes are ingeniously conceived, his characters boldly and clearly drawn; and he never falls beneath a high level of stage effect.

Shirley's tragedies are: *The Maides Revenge* (acted, 1626; printed, 1639); *The Traytor* (licensed, 1631; printed, 1635), which Dyce reckoned as Shirley's best tragedy; *Love's Crueltie* (1631; printed, 1640); *The Duke's Mistris* (acted, 1636; printed, 1638); *The Polititian* (acted, 1639; printed, 1655); *The Cardinal* (acted, 1641; printed, 1652), a good example of Shirley's later style, and characterized by Edmund Gosse as perhaps the last great play produced by the giants of the Elizabethan age. His comedies are: *Love Tricks, or the School of Complement* (licensed, 1625; printed under the latter title, 1631); *The Wedding* (licensed, 1626; printed, 1629); *The Brothers* (acted, 1626; printed, 1652); *The Wittie Faire One* (acted, 1628; printed, 1633); *The Gratefull Servant* (licensed in 1629 as *The Faithful Servant;* printed, 1630); *Changes: Or Love in a Maze* (acted and printed, 1632); *Hide Parke* (acted, 1632; printed, 1637); *The Ball* (acted, 1632; printed, 1639); *The Bird in a Cage* (acted and printed, 1633), ironically dedicated to William Prynne; *The Young Admirall* (licensed, 1633; printed, 1637); *The Gamester* (played at court, 1634; printed, 1637), written at the command of Charles I., who is said to have invented or proposed the plot; *The Example* (acted, 1634; printed, 1637); *The Opportunity* (licensed, 1634; printed, 1640); *The Coronation* (licensed, 1635, as his, but printed, 1640, as by Fletcher); *The Lady of Pleasure* (licensed, 1635; printed, 1637); *The Constant Maid, or Love will find out the Way,* printed in 1640 under the former title with *St. Patrick for Ireland; The Royall Master* (acted and printed, 1638, ed. with critical essay in C. M. Gayley's Representative English Comedies, New York, 1914), an excellent comedy of intrigue, with an epilogue addressed to Strafford; *The Doubtfull Heir* (printed, 1652), licensed as *Rosania, or Love's Victory* in 1640; *The Gentleman of Venice* (licensed, 1639; printed, 1655); *The Imposture* (acted, 1640; printed, 1652); *The Sisters* (licensed, 1642; printed, 1653); *The Humorous Courtier* (perhaps identical with *The Duke,* licensed, 1631), printed, 1640; *The Court Secret* (printed, 1653). *Poems* (1646), by James Shirley, contained "Narcissus," and a masque dealing with the Judgment of Paris, entitled *The Triumph of Beautie. A Contention for Honour and Riches* (1633) appeared in an altered and enlarged form in 1659 as *Honoria and Mammon.* In 1653 a selection of his pieces was published as *Six New Playes.* He wrote the magnificent entertainment presented by the members of the Inns of Court to the king and queen in 1633, entitled *The Triumph of Peace,* the scenery being devised by Inigo Jones and the music by W. Lawes and Simon Ives. In this kind of composition he had no rival but Ben Jonson. His *Contention of Ajax and Ulysses* (printed, 1659) closes with the well-known lyric, "The Glories of our Blood and State."

The standard edition of Shirley's works is *The Dramatic Works and Poems of James Shirley, with Notes by William Gifford, and Additional Notes, and some Account of Shirley and his Writings,* by Alexander Dyce (6 vols., 1833). A selection of his plays was edited

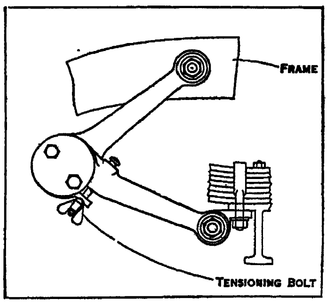
(1888) for the "Mermaid" series, with an introduction by Edmund Gosse. *See* R. S. Forsythe, *The relations of Shirley's plays to the Elizabethan drama* (1914).

SHIRLEY, WILLIAM (1694–1771), colonial governor of Massachusetts, was born at Preston in Sussex, England, on Dec. 2, 1694. He studied law, entered the Middle Temple, emigrated to Massachusetts in 1731, was appointed "the King's only advocate-general in America" (*i.e.*, of all New England except Connecticut) in 1734, and in 1741, while representing Massachusetts in a boundary dispute with Rhode Island, was appointed governor. The most important event of his administration was the conquest of Louisburg in 1745. The expedition was undertaken on his suggestion and its success was largely due to his energy and enthusiasm. In Sept. 1749, £183,650 (English) in coin was brought to Boston to cover the outlay of Massachusetts, and largely through Shirley's influence this was used for the redemption of outstanding paper money, thus re-establishing the finances of the province, a subject to which Shirley had given much attention.

Both in the colonies and in England, whither he returned in 1749 on leave of absence, Shirley kept up an active agitation for the expulsion of the French from the whole of Canada. He went back to Massachusetts as governor in 1753; led an unsuccessful expedition against Ft. Niagara in 1755, and after the death of Gen. Edward Braddock (1755) until June 1756 was commander-in-chief of all the British forces in America. In Sept. 1756 he was recalled to England and was succeeded as governor by Spencer Phips. He was governor of the Bahamas until 1770, then again returned to Massachusetts, and died at Roxbury, March 24, 1771. He published a *Journal of the Siege of Louisbourg* (1745), and *The Conduct of General William Shirley Briefly Stated* (1758).

SHOA, the southern of the four former principal provinces of the Abyssinian empire. Shoa from about the middle of the 10th century till nearly the close of the 13th century was the residence of the Abyssinian sovereigns, who had been driven out of Axum, their former capital. About 1528 Shoa was overrun by Mohammedan invaders and was for over a century afterwards a prey to Galla raiders. It remained independent of northern Abyssinia until 1855 when the emperor Theodore reduced it to submission. In 1889 Menelek II., king of Shoa, on the death of the emperor John, made himself master of the whole of Abyssinia. The principal town, Addis Ababa (*q.v.*), is now the capital of the empire (*see* ABYSSINIA).

SHOCK ABSORBER is an elastic medium which absorbs the heavier shocks given to road vehicles. One type consists of two arms pivoted together, with their ends connected to the frame and axle. Tension is imparted to the pivot joint by flat friction discs, or by a band brake with friction lining, as in the absorber made by Frank Smith and Co. Ltd., of Elland, and shown here. As the axle rises the arms move towards one another, which movement acts on the tension spring so allowing the band to slide freely round the brake drum. On the rebound the arms separate, and the band coils round the drum, thus absorbing the excess energy stored up in the spring during the compression movement. The tensioning bolt has four indicating grooves in its head to enable uniform adjustment to be given to each absorber. Grease is supplied to the friction surfaces by a special lubricant packed inside the drum, and automatically feeding through two slots to the friction surfaces. To assist lubrication under all climatic conditions a paddle is fitted, with a hexagon head, to be oscillated with a spanner at about every 1,500 miles. There are many types of shock absorbers in use in the United States on motor vehicles.



BY COURTESY OF FRANK SMITH (ELLAND)
FRICTION ARRANGEMENT WHICH DAMPS OUT BOUNCING OR ROLLING OF A CAR ON ITS SPRINGS

The term shock absorber is also applied to spring fittings in large power chain drives for factory and other installations. Instead of making the sprocket-wheel solid, it has a separate rim which presses against a set of peripheral coiled springs, and so starting and variable impulses are absorbed quickly by the springs without stressing the chain.

SHOCK and **COLLAPSE.** A severe injury which is not sufficient to kill may yet so derange the mechanism of the body that even a casual observer can correctly judge how little extra hurt would be necessary to cause death. In lesser degrees of injury a trained observer is able to detect derangements which must be regarded as early stages of the more serious conditions which compel observation. The name given to this depressed condition of the body is "shock" and when consequent on injury it is known as traumatic shock.

Shock has been studied chiefly in connection with injury and many would limit use of the term to the results of trauma. It is undeniable however that conditions of the body very similar to those produced by severe external injury may follow various accidents of disease, *e.g.*, perforation of a gastric ulcer or strangulation of a coil of intestine—so that it is wise to take a broader view of the subject. This is the more necessary since Dale has shown that injection into the body of minute doses of histamine—a protein decomposition product—will produce an almost exact simulation of shock. Similar symptoms may also be produced by the entry into the circulation of poisons formed in obstructed small intestines, or of products of muscle-disintegration after injury, or of bacterial products in peritonitis. It is convenient therefore to apply the term shock to the common state and to designate the particular type by a qualifying adjective, *e.g.*, traumatic, toxic, protein or haemorrhagic shock. The word collapse is rather loosely used to indicate the same condition as shock. Various contradictory and unsatisfactory efforts have been made to distinguish between shock and collapse. There is no doubt that collapse suggests something rapid and a close approximation to the common significance of the term would be "the rapid onset or aggravation of the symptoms of shock."

The symptoms of severe shock are very characteristic and consist chiefly of a failure of the peripheral circulation with accompanying (and partly consequent) diminution of all the metabolic processes of the body. There is in addition some increased activity of the sympathetic system as shown by the sweating and dilated pupils. The affected person is usually pale or livid, the extremities and nose cold, the pulse small and weak, and frequently more rapid than normal. The blood-pressure is as a rule lowered and tends to diminish as the condition progresses. The mental processes are commonly sluggish and the muscles relaxed. The secretions are diminished with the exception of sweat which may be poured out in great quantities. Though pain itself may produce shock yet in severe cases of shock, pain is usually not a complaint. The temperature is usually subnormal, registering 95° or 96° F. The clinical measure of the degree of shock is usually made by an estimation of the blood-pressure. In severe shock the systolic blood-pressure usually goes below 100mm. of mercury and sometimes drops to 80 or even 60mm. Recovery rarely takes place if a lower register than 50mm. is reached. Sometimes the systolic pressure does not fall so low but the pulse-pressure (difference between systolic and diastolic pressures) drops from the normal 50 down to as little as 20mm. These measurements afford a ready proof of circulatory failure.

Though in well-defined shock all the indications are present there are many occasions when one or more of the classical symptoms are wanting. Occasionally a slow pulse may accompany even severe shock whilst very obvious appearance of shock (subnormal temperature, sweating, pallor) may exist with only a slight or even no fall in blood pressure. Mental dullness is another rather variable factor for in many cases of toxaemic shock the mind may be very alert.

The pathology of shock has been the subject of much research and difference of opinion. Most of the experimental work has been concerned with traumatic shock and has been performed on animals. Clinical work has been concerned chiefly with shock following operation—a particular type of traumatic shock. It is agreed that prolonged over-stimulation of peripheral nerves will cause shock in proportion to the intensity of the stimulus and the

able weather prevents regular and sufficient burning of old heather, and so prevents the growth of young heather; it prevents heather from ripening its seed, and so lessens the food supply of grouse in winter; and it prevents the proper regulation of the size of the grouse stock on the moor. In a word, it reduces food supply, and the provision of a sufficient supply of food is the single key to successful moor management.

Partridge Shooting.—Partridge shooting, like grouse shooting, can be separated as regards methods into two categories—walking up and driving. The former is the older form of the sport and still has many adherents—probably, indeed, the majority of partridge shooters prefer walking. Certainly it is a method which has its own charm, partly of old association, partly of simplicity, partly doubtless of September weather. A single gun may go out by himself, or with a companion, or if there is plenty of ground available, there may be a line of four or five guns—any larger number is apt to be cumbrous. The general proceeding on a September morning is to walk the stubble fields so as to drive the coveys into roots or other cover, and then to walk each piece of cover in turn so as to flush the coveys and to send them in the direction of other cover which can be walked in the same way. Working the different fields of a farm in this way needs careful planning and a certain knowledge of the natural habits of partridges, which is one of the chief claims to consideration that the sport of walking up must have for the country sportsman.

In driving partridges, the purpose of the shooters is to collect a number of coveys into a field or strip of roots lying alongside a fence, on the other side of which are posted the guns. If possible, these guns should stand in a grass field or on stubble, in order that the partridges killed in the drive may be collected easily and quickly. A drive begins with a line of beaters, with flankers working on the right and left of the line, advancing over a chosen number of fields and driving the partridges before them towards the selected strips of roots. The beaters and flankers carry flags, the latter being charged with the duty of waving their flags so as to keep the birds from breaking out at the sides. Throughout, the head keeper (or possibly the host) is in charge of the drive, and it requires a considerable knowledge of the country and of wind and weather to ensure success. The beaters on reaching the strip of roots into which the coveys have been driven advance slowly and the partridges are flushed so as to fly over the fence behind which stand the guns. As they top the fence and catch sight of the guns the birds swerve and swing in every direction, with a disconcerting suddenness that tests the quickest eye and hand. Indeed, there could be no higher criterion of the all-round skill of a game shot than to describe him as first rate with driven partridges.

Pheasant Shooting.—Pheasant shooting, compared with grouse and partridge shooting, is an artificial business; or it is true, at all events, to say that only under more or less artificial conditions can pheasants supply the sporting chances of shooting which modern sportsmen prefer. Wild pheasants, to speak generally, make dull work for the gun. It is a pheasant's natural instinct to run rather than to fly, and if forced to fly, to regain shelter as soon and as near as possible. Therefore when a covert containing wild pheasants is beaten out, few of them will be found to fly high or far, or to go straight in any particular direction; the birds will fly out anyhow and anywhere, possibly back over the beaters' heads. Only a small proportion can be put over a line of guns, and the shots offered will be poor and uninteresting.

With hand-reared pheasants the case is different. A line of beaters enters the wood in which the pheasants are fed, and pushes them out by advancing slowly and tapping the trees quietly; the birds run before the advancing line and can be pushed in this way, either running or flying low from one wood to another, until they have been manoeuvred into a covert previously chosen, at the far side of which is placed a line of stops, that is, men or boys tapping trees, fences, etc.—beyond which the pheasants will not go. When the birds are collected into this covert the guns will take up their position in a line between the covert and the birds' home; the keeper and one or two chosen assistants then enter the covert, and flush the birds a few at a time. The pheasants thus put on the wing rise into the air with the object of regaining their "home," and as a rule will attempt to do so in a single flight. It is upon this home-flying habit of pheasants that the whole principle of modern covert-shooting is founded, and there can be no question that pheasants flying in this way, high in the air and at a great pace, and often swerving or curling in a high wind, provide as exacting a test of skilled shooting as is possible.

Black Game, Ptarmigan and Capercailzie.—Most of the shooting of other game in Great Britain is corollary to the sport to be had with grouse, partridges and pheasants. Black game, for example, are to be found in most places where there are grouse, and the methods of shooting the two species are identical. Ptarmigan, on the other hand, belong only to the higher ranges of grouse country, or perhaps, rather, deer forests, and if walked up provide uninteresting shooting owing to their tameness. Capercailzie may occasionally be found on the open moor, but only in the neighbourhood of trees; the name is "cabhar coille," or cock of the wood, and it is in the heart of pine and fir woods that the capercailzie makes its home. The birds are driven in winter, and afford remarkable shooting, for they sail out from the trees over the glen at a great pace, and may easily be out of shot.

Snipe Shooting.—Two or three other forms of shooting may be pursued for their own sake. Snipe are to be found on most grouse moors, but snipe shooting is a sport by itself, to be enjoyed wherever there is bogland adapted to the snipe's feeding habits. The bird rises from the ground like a flash, twisting this way and that, and to hit so elusive a mark needs a quick eye and hand. Snipe-shooting is a sport of the winter months, for the home-bred birds are joined by the migrations from the Continent in November. The largest bags of snipe have been made in the Hebrides, but Ireland and Wales, especially the former, provide some of the best snipe ground, and in England there are possibilities of good shooting in Norfolk.

Woodcock.—Woodcock shooting, as a sport by itself, belongs principally to certain localities on the line of the birds' migration. As is the case with snipe, large numbers of woodcock arrive every autumn from the Continent, and pass through the British Isles in a general direction from north-east to south-west. The furthest limit of this migration is the west and south-west of Ireland, and the shooting at Ballykine and its neighbourhood on the shores of Lough Mask is possibly the best in the world. But large bags are obtained in Cornwall, which is the limit of the line of flight in England, and in the west of Scotland, particularly the isle of Islay, which is a stage of the birds' migration both on the outward and homeward journey. The supposed difficulty of the shooting arises from the erratic movement of the bird, whose sight is adapted for night conditions rather than day, when flying among trees. A woodcock in the open is a comparatively simple mark.

Hares and Rabbits.—Ground game provide shooting which is variously regarded as sport according to the standards of the shooter. Hares, which are destructive to crops, have to be shot down but hare-driving produces few opportunities for interesting work with a gun. But rabbit-shooting may afford considerable tests of hand, eye and brain, for a rabbit gets to its top speed in an amazingly small space of ground, and takes every advantage of cover and obstacle. The main methods of shooting rabbits are two—ferreting and laying out. In the former, ferrets are put to ground in the rabbits' burrows, or "buries," and the little animals are shot as they bolt from the holes. The sport varies with the condition of the weather; if it has been fine at night, and the rabbits have fed well, they are sluggish and disinclined to move; if they have been kept in by rain—for rabbits dislike a wet jacket—they will bolt quickly, or dodge from one hole into another, offering only the chance of snap shooting. If the second method, that of laying out, is adopted, the procedure is different. A day or two before the shoot, the gamekeeper goes the round of the buries with some sort of evil-smelling mixture, such as paraffin and tar, which he sprinkles into each hole. The rabbits leave their holes at night to feed, but do not return to them, objecting to the smell. The keeper the next morning fills in every hole, and on the day of the shoot the rabbits are found lying out in the undergrowth, from which they are dislodged by beaters with sticks,

or by spaniels. In the south of England a pack of beagles is sometimes used for this purpose.

Wildfowl.—Sport with wildfowl must always be of an uncertain nature, since it depends largely on the weather. The harder the weather the better, so far as the wildfowler is concerned, since gales bring the fowl in from the sea to shelter and frost confines the spaces of water where they can feed by night and rest by day. Sport with wildfowl may be enjoyed by following two methods. One is that of the shore shooter, who waits at dawn and dusk at certain points over which he knows the duck will pass when flighting to and from their day and night quarters. He will need both for use and for friendly company a well-trained retriever, or he will not be able to pick his birds in the dark or from the water into which they may have fallen. The other method is that of the punt-gunner, who sets up to his fowl in a flat-bottomed boat carrying a heavy swivel-gun, firing anything from 1 lb. to 2 lb. of large size shot, with which he shoots at duck on the water or as they rise. This is a form of sport which is followed by probably a decreasing number of persons, but is one which requires a strong constitution, patience and endurance, and is perhaps more exciting and also more dangerous than any other shooting of its kind.

The art of shooting is not to be taught in words; it is a matter of practice. But practice should be begun on right lines; this is an easier proceeding to-day than it used to be, for one of the modern developments of the gun trade is the shooting school which the best firms place at the disposal of their clients, where the use of the gun can be learned together with the elements of the etiquette of the shooting field. The beginner should always be fitted with a gun, and the fitting again, is part of the gunmaker's business. For different purposes different types of weapon are necessary, but for all round work a 12 bore hammerless ejector, weighing say $6\frac{3}{4}$ lb. and firing cartridges loaded with $1\frac{1}{16}$ oz. of shot with 42 grains of Schultze or 34 grains of E.C. may be recommended.

GAME SHOOTING WITH DOGS IN THE UNITED STATES

Development of gun dogs in the United States has covered a range of breeds and fields for their respective hunting activities ranging from fox, deer and bear hounds, through the rank and file of Chesapeake bay, Irish water spaniel and springer spaniel water retrievers, on into the ranks of pointers and setters (*see* DOG: *Setters and Pointers*). The last-named breeds constitute the main stem of upland game workers as differentiated from marsh dogs. It might be well, in order definitely to establish his entitled place in the record, to recall with full credit a type of gun dog now practically extinct along the vanishing frontiers. This was the sturdy, upstanding settler's dog, a combination strike dog and trailer, capable of helping to provide meat for wagon train, camp or home, and also of acting as watch dog and cattle herder.

"Hounding" game with dogs, save in the pursuit of predatory bears, wolves, lynx and coyotes—and then only by permit—is a practice now more or less barred by most State game codes and falling more and more into disuse, as being against the sounder principles of conservation. When game abounded, and the country, particularly in the south, was a thickly wooded and almost impenetrable barrier of windfall and swamp, "hounding" was the recognized and thorough-going arm of a royal sport and race of men. Plantation owners and ranchmen bred and trained magnificent packs capable of imparting an almost exalting contagion to the spirit of good hunting and the hardihood of its followers. To-day, hounding is confined almost wholly to fox-hunting, coon and rabbit hunting. As a gun dog, the hound attained a rating of high efficiency when broken to follow only given scents. Slow running, cold-nosed strike dogs, sticking with their trailing mates to specific quarry and deserting it for none crossing, were the dogs before which much of the country's game supply fell to waiting sportsmen. That the American hound could be trained to run dangerous foreign game was demonstrated when the late Paul J. Rainey selected well-broken stock from several of the country's best big game packs and sent them to Africa with Shelley. Shelley, a master-hand at such work, remained in Africa off and on for 13 years, making record kills of lion hunted by his American hounds. Hunting lion, leopard, cheetah, etc., with hounds, is not now permitted in the Kenya Colony of British East Africa.

Half-bred American hounds and airedale terriers also have been used to hunt mountain lion, panther and other of the large Carnivorae in North and South America. A good hunting rather than a game or plucky hound or dog is the better for following the powerful and more savage wild animals against which the aggressive dog has no chance, the rifle, *not* the dog, being the implement used for destruction.

A pack of rough-haired Welsh foxhounds—a breed celebrated for its great scenting powers—imported by Erastus Tefft, of Brewster, N.Y., in 1928 ran and killed 14 out of 20 foxes they found in Putnam County, N.Y. This probably constituted a record in the annals of American foxhunting with hounds that not only kill but eat their foxes.

A conception of gun dogs in the United States, however, rests in the main upon those breeds best adapted to finding, pointing and retrieving game from marsh and upland. Setters and pointers unquestionably occupy the more prominent station with reference to the gun. They are of several strains, foundation stocks of which were imported from England. Llewellin, Gordon, Lavarack and Irish constitute the main stems in setter blood. In many instances these strains have been inter-bred, which doubtless accounts for the enormous number of so-called cold-nosed or unregistered bird dogs of all breeds. In addition, pointers and setters have, at times, been knowingly or unknowingly cross-bred. Such progeny are classed in bird dog parlance as droppers. In a few cases droppers have turned out splendid gun dogs, seeming to possess, in addition to sound bird dog instincts, the ability to trail and tree squirrels and wild turkey. In the main, however, little if any attention need be paid to such mistakes in canine offspring. Long and short hair, setter and pointer conformation are sometimes found together in the same litter of droppers.

The Best Gun Dogs.—Three types of gun dog aristocracy are found in the blooded lineage of the United States: bench-show individuals, shooting dogs and field-trial dogs. The true shooting dog is usually pedigreed, thoroughly broken to the gun and possessing the brain and stamina, nose and bird-sense which constitute the acme of class and reflect pride of ownership to a true bird-hunter. The field-trial dog is bred for and trained to the rigours of competitive bird-finding, the acid test of great speed, heart, ability to locate and, what is of paramount importance, ability to handle game and be handled. By handling is meant (in addition to all other demands of the competition,—bird sense, finding, steadiness to shot and wing, etc.) the dog's acute perception and intelligent execution of its trainer's direction on the field-trial course.

Types of upland gun dogs vary with the game sought and terrain to be covered both by dog and hunter. In heavily bushed and wooded grouse and partridge coverts the dog required is a strong, keen-nosed individual of somewhat restricted range as compared to the needs for freer upland casting. Handling such birds is a distinct phase of gunnery both for dog and master, the supreme importance of stance and signal in thick cover being obvious in sizing up limited space and opportunity for enforced quick-pointing and snap-shooting. Good individuals on grouse or quail would doubtless find their respective abilities badly at sea were they to

are extremely simple in their decoration. The more recent Dutch store design has completely emancipated itself from the domestic store policy and has broken every restriction either of form or of use of material. These façades are interesting experiments though it is more than likely that another generation will choose certain elements of strength from which to evolve a simpler and less bizarre form of building.

On the whole, the variation between the store preceding the 19th century and our own type is essentially that of a change in business policy; the larger store developing from a bazaar into a great organization has required monumental buildings. At the same time, a parallel development of the specialized store has resulted in the construction of special settings for the display and sale of merchandise requiring environment, as, for example, small shops, candy stores and the particularly American development of the drug store which is quite in sharp contrast to the dignity of the apothecary of Europe. With the development of the modern store and the distinctly modern use of large sheets of glass, the frame of the store, in many instances, has become the band enclosing the expanse of display within. The only reasonable explanation of this boldness is the demand for sudden changes of display—hardware in the morning to clothes or food in the afternoon. Under such circumstances the less striking the setting the simpler the problem of the window designer. (E. J. K.)

Technique.—The great development in recent years in the design of shop fronts has been caused by the growing expanse of display space, the use of new materials and the intensification of sales technique. The modern shop front is designed as a picture frame for the contents of the window and also as a means of attracting customers at long range. Intelligent merchants have discovered that mere expanse of plate glass is not enough. In other words, the picture needs a frame, but at the same time, the frame must not be so important that it overpowers the picture. The attraction of customers from a distance offers a more difficult problem—the reconciliation of the desire of the shopkeeper to have his shop as conspicuous as possible with the desire to preserve the beauty of the street as a whole. It is obtained by richness of material, interesting form, prominent signs, bright colours, strong lighting.

The extent of display space has been increased by new types of glass joints, metal mouldings and deep vestibules with elaborate convolutions of plan, so that even on a short frontage a large display is possible—more powerful lights and greater control by colour screens and spotlights, together with a great advance in the art of window dressing have added to the effectiveness of the display itself. Show window interiors should be designed as a background for the display, not so dark as to absorb light or so light as to make prominent shadows, or of a colour or treatment so strong as to overpower the display. The display itself is treated as a composition of sculpture or painting, arranged in mass with stands and drapery and accented by lighting. (R. H. S.)

Modern Tendencies.—In the modern store, wood and plaster have practically disappeared and the use of marble, stone, bronze and the less expensive materials, such as cast iron, copper and quite recently polished rustless steel, is usual.

As a matter of solution of design, the stores in America have not shown great brilliancy in spite of the tremendous opportunities that have been presented. This, in large measure, is due to extreme conservatism. Two influences appear in recent years: one, an attempt to introduce into store design the principles of the Colonial or English Georgian architecture, and many excellent examples of store fronts are now in evidence throughout New England. The very close derivation of detail from historic sources has produced charm of design and intimate scale that is in thorough sympathy with the buildings surrounding the shop. The other tendency has been to copy the specialty store, as was particularly developed in Paris during the 19th century, and up to this particular day, the theory being largely that of creating a striking frame for a very special display of goods. In quite a number of these stores, however, where the designer has proceeded with a free hand in the solution of a problem, unusually excellent results have been obtained, and on a number of the streets in Paris examples of these stores may be seen. The Rue St. Honoré, the Rue de la Paix, Avenue de L'Opéra and the Rue Royale, in Paris, as well as Unter den Linden and the Kurfürstendam, in Berlin, are especially to be noticed and there the variety of design is almost as extensive as the quality of merchandise which the stores contain. In these various stores the proportion and size of the show window are in direct relation to the scale of the merchandise in the store. The back of the window is very often made an interesting part of the composition, but it is not clear that this element of design is of sufficient importance to warrant comparison with the well developed façade and the illumination within.

Fifth avenue, in New York, has a character thoroughly at variance with the streets noted. Although the original theory of the shopkeeper had quite simply been a willingness to adapt European forms, the rapid development of the Avenue has forced serious changes in style in so breathless a form that the description is difficult. At one period, particularly at the beginning of the 20th century, the classic revival produced excellent varieties of Italian palaces transformed into stores that are slowly feeling the pressure of business changes. The uneven sky-line which the daily rebuilding further exaggerates tends to complicate the problem by presenting difficult questions of scale. The struggle seems to lie between the policy of the large show window of the Altman, Bonwit Teller and Franklin Simon store type as against the smaller window and larger wall surface as exemplified in the Cammeyer, Dobbs and Bergdorf-Goodman stores. The tendency on Fifth avenue has been thoroughly conservative and its appearance, in spite of the restraint, is dignified and well worthy of the most important shopping district in the country.

In Germany, the illumination of the exterior and the interior of the window has been greatly exploited by the use of tubular lamps which, on occasion, frame the store opening, or where the same lamps are used to develop a store name and appear during the day as letters against a proper background, at night presenting a brilliant design against the dark surface of the building. These tubular lamps do not throw a large amount of illumination but show themselves as brilliant units of glowing colour. In Germany, likewise, the use of sheets of glass is to be noted, wherein varying possibilities of effect are produced. In some cases a white glass is used to form surface patterns through which, at night, light is thrown, thereby presenting a very brilliant impression to the street. This is particularly noticeable in restaurants or stores where the major requirement is a sensational effect. Another use of the glass is in the application of sheets of opaque material; blue, black and white glass acting as a veneer, either framed in metal or bolted to the wall as purely decorative material. Throughout France and Germany, mosaic has been extensively used, and the possibilities of colour effect which this material permits appear to be unlimited.

In Paris, the large stores, as contrasted with the specialty shops of the streets before mentioned, have developed a design extremely characteristic of Paris. The Printemps, Bon Marché and the Galleries Lafayette have, during the past few years, redesigned their façades, not only to keep abreast of the modern note in design, but to maintain the public's interest, apparently in their own evolution. It is quite likely that Paris, being a cosmopolitan city, requires more active development than similar cities in the United States or England might find advisable, and it is likewise obvious that according to American and English standards French stores are somewhat over-elaborate. There must be a nice balance between the interesting frame and the merchandise within, quite in the same proportion that a painting or a piece of sculpture requires careful handling to be enhanced by its background. In spite of this criticism, however, the French stores unquestionably are of great interest and apparently hold the popular enthusiasm through their present policies.

The German stores, in particular the Wertheim building, designed by A. Messel in 1905, and which is still the prototype for big store design in Germany, resemble the French stores in their elaboration, with profuseness of carving and decoration, explaining a period when money was available for such use. It would seem to be a happy misfortune that the requirement for economy

MODERN TREND IN SHOP FRONT DESIGN

1. The John Ward shop, 555 Fifth Avenue, New York, designed to provide large display space for small frontage. Floor of round windows may be lowered to basement for arranging
2. Galéries Lafayette, Paris. Glass faceted marquise attracts the eye from a distance and gives light and shelter to those wishing to inspect the display more closely
3. Thom McAn shop. Beveled windows allow distant vision. Reflections kept from display by sloping glass
4. Delman, Madison Avenue and 54th street, New York. Large oval window with figures in motion attracts attention. Small windows below make for intimate effect
5. Lucky Strike, Broadway and 45th street, New York. Odd shaped corner window with moving figures and machinery used to attract attention of passers-by
6. Extensive amount of glass is used in the Peter Sorensen shop in Copenhagen, Denmark, one of the greatest shops for the sale of shoes in that city
7. Delletrez, Fifth Avenue near 57th street, New York. Effect obtained by use of rich materials, original forms and delicacy of treatment

in Germany to-day is causing the designers to simplify the forms to a point where effects are obtained with a great reduction in decoration and more emphasis on proportion, colour and purity of form.

Among American examples might be noted the work of Louis Sullivan, in New York and Chicago, in particular the Carson Pirie Scott and Co. store which, although most exuberant in detail, shows an interesting variance in pattern from the work of its day. The former Alexander shoe store on Fifth avenue was a very interesting example of a specialty store design to frame a very particular business, and although it has changed its occupancy it still remains one of the fine examples of design on the most important street in America. The Gattle jewellery store on Fifth avenue likewise shows a type of store that had considerable influence on other store designs, through the shape of its windows, arrangement of display and more particularly the unusual placing of marble and glass. The Bergdorf-Goodman store at 58th Street and Fifth Avenue is characteristic of the new store in the most exclusive district of the city, where restraint and dignity would seem to be dominant.

SHOP STEWARDS. Prior to 1914, shop stewards in Great Britain were confined to certain of the skilled trade unions. The duties of the shop steward were to inspect trade union contribution cards at regular intervals, to recruit new members for the union, to keep a watch on possible encroachments in the trade of other sections of labour, and to report regularly to the trade union branch or district organisation which he represented on matters arising in the workshop demanding official attention. In some cases he was also responsible for representing grievances of members of his union in the workshop to the management. His powers were, therefore restricted. The conditions of wartime led to the assumption of new functions by shop stewards. The official trade union organisations were parties to the industrial truce agreed upon at the beginning of the war, and in any event, their machinery was too cumbrous to deal with the questions which arose from day to day in almost every munitions factory.

During the war, therefore, shop stewards became negotiators and superseded in a large degree in factories and workshops engaged on war production, the ordinary official machinery of trade union negotiation. At the end of the war, the restoration of more normal conditions broke the power of the shop stewards. They have, however, in many unions now become a normal part of Trade Union organisation. Shop stewards have been appointed in factories and workshops in a variety of industries where they did not exist prior to the war. In addition to carrying out their well established duties, they are in some industries empowered to negotiate on minor matters, but their negotiating powers are derived from the unions and are not exercised independently of the unions as was so frequently the case during the war. (*See* Trade Unions.)

SHORE, JANE (d. 1527), mistress of the English king Edward IV., is said to have been the daughter of Thomas Wainstead, a prosperous London mercer. She was well brought up, and married young to William Shore, a goldsmith. She attracted the notice of Edward IV., and soon after 1470, leaving her husband, she became the king's mistress. Edward called her the merriest of his concubines, and she exercised great influence; but, says More, "never abused it to any man's hurt, but to many a man's comfort and relief." After Edward's death she was mistress to Thomas Grey, marquess of Dorset. She also had relations with William Hastings, and may perhaps have been the intermediary between him and the Woodvilles. At all events she had political importance enough to incur the hostility of Richard of Gloucester, afterwards King Richard III., who accused her of having practised sorcery against him in collusion with the queen and Hastings. Richard had her put to public penance, but the people pitied her for her loveliness and womanly patience; her husband was dead, and now in poverty and disgrace she became a prisoner in London. Thomas Lynom, the king's solicitor wished to marry her, but was apparently dissuaded. Jane Shore survived till 1527; in her last days she had to "beg a living of many that had begged if she had not been." She figured much in 16th-century literature, notably in the *Mirrour for Magistrates*, and in Thomas Heywood's *Edward IV.* The legend which connected Jane Shore with Shoreditch is quite baseless; the place-name is very much older.

Bibliography.—Most of our information as to Jane Shore comes from Sir Thomas More's *Life of Richard III.*, edited by J. R. Lumby (Cambridge, 1883), supplemented a little by Edward Hall (*Chronicle*, pp. 363–364). *See* also H. B. Wheatley's edition of Percy's *Reliques*, ii. 264 (1876–77), and J. Gairdner's *Life and Reign of Richard III.* (Cambridge, 1898).

SHOREDITCH, an eastern metropolitan borough of London, England, bounded north-west by Islington, north-east by Hackney, east by Bethnal Green and Stepney, south by the City of London, and west by Finsbury. Pop. (1931) 97,038; area 658 acres. It is a crowded district extending east and west of Kingsland Road. An old form of the name is *Soersditch.* The metropolitan borough of Shoreditch returns one member to Parliament.

SHOREHAM, a seaport in Sussex, England, near the mouth of the River Adur, 6 m. W. of Brighton. Pop. of New Shoreham (1931) 8,757. The town is sometimes known as New Shoreham, in distinction from the village of Old Shoreham, a mile distant, which was the former port. Shoreham owed its early importance to the natural harbour formed by the River Adur. It became an important port in the 13th and 14th centuries, but was later much reduced, doubtless owing to the encroachment of the sea. The port revived during the reign of George III., when acts were passed for securing and improving the harbour which was continually becoming silted up by the tides and tending to move eastward. Shoreham was called a borough in 1236. Weekly markets and an annual fair dating from the time of Edward I., were held for some centuries, but have now been discontinued. Shipbuilding has always been the chief industry, and was largely carried on in the 13th and 14th centuries. There is also trade in coal, grain, timber and cement. The public boys' school of St. Nicholas, Lancing, is near Shoreham.

SHOREY, PAUL (1857–), American classical scholar, was born at Davenport (Ia.), on Aug. 3, 1857. He graduated at Harvard university in 1878, and was admitted to the Chicago bar in 1880. He then continued his studies at the universities of Leipzig (1881–82) and Bonn (1882) and the American School of Classical Studies, Athens (1882–83), proceeding thence to the University of Munich (Ph.D., 1884). He was professor of Greek at Bryn Mawr college 1885–92, resigning to fill a similar chair at the University of Chicago. He became head of the classical department at Chicago in 1896, and was Roosevelt professor in the University of Berlin (1913–14). Dr. Shorey wrote: *De Platonis Idearum Doctrina* (1884); *The Idea of Good in Plato's Republic* (1895); *The Odes and Epodes of Horace* (1898); *The Unity of Plato's Thought* (1903); and *The Assault on Humanism* (1917), the last named a brilliant but bitter polemic directed chiefly against those who minimized the value of humane studies in the educational system. He became managing editor of *Classical Philology* in 1908, and was a constant contributor to its columns.

SHORING is the scientific placing of supports to parts of a building which are liable to distortion or collapse either because the fabric of the building is unsound—which may be evidenced by failure or settlement—or to guard against the disturbance of adjacent parts of a structure and adjoining premises where alterations to the fabric are being made. The word "shore" means a prop or support and is applied to the work under description because every member employed is virtually a prop or a strut, opposing movement by its own resistance to compression. The craft of shoring lies in so placing the shoring members and forming the joints and connections, that the shores as a whole may

function perfectly; this condition requires that all parts shall fit closely and squarely at their ends and to be brought into close contact without "shock" to the structure which is being operated upon. Wedging requires the use of the hammer, causes shocks and vibration and should be used as little as possible; though it cannot be dispensed with entirely. Where wedges are adopted they should be placed at the ends of members distant from the defective portions of the structure and great care must be exercised in using the wedges, which should be slowly and cautiously driven by gentle blows.

In all shoring it is imperative to *maintain* the condition of the structure to which it is applied, not to *disturb* it, or to attempt to restore it to an original position. There are several different forms of shoring, each adapted to suit particular circumstances. Much ordinary shoring is done with heavy, roughly sawn timbers strongly braced together, but for heavy work steel members may be introduced with advantage. Generally, steel is only employed for short heavy beams called "needles" (*see* below *Dead Shoring*), but in some special cases, as in the restoration of the piers supporting the dome of St. Paul's cathedral, shoring and scaffolding must necessarily be of steel to support the immense loads during repair operations.

The form of shore in most general use is that known as the *raking shore.* It consists of one or more timbers sloping from the face of the structure to be supported and bedded upon the ground. When the ground is of a yielding nature, a stout timber plate termed a sole-piece, is placed to receive the base of the raking timber or timbers. A wall-plate, to increase the area of support, is fixed to the face of the wall by hooks driven into the joints. Where space is available, a slope of 60° is found convenient for the main shore, the auxiliary members ranging in their slope from 45° to 75°. In many cases, especially in towns, the angle of slope is governed by outside influences such as the width of the footway or by local regulations. Raking shores are erected singly or in "systems" in planes at right angles to the face of the wall. The members rise fanwise from the sole-plate to support the wall at different points. The spacing between systems depends on the condition of the building to be supported, and also upon the spacing of its window and other openings. The usual spacing is 10 ft. to 15 ft. apart, but depends upon the openings in the wall. The application of the shores needs care, support being given only where there is a corresponding thrust from a floor or roof. A clear idea of the construction of a system of raking shores can be obtained from a study of the illustration (fig. 1). The names and functions of the different timbers are indicated here.

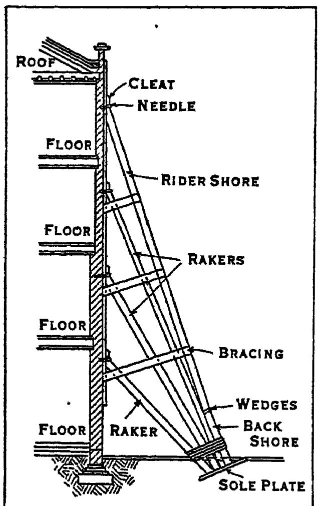

FIG. 1.—SYSTEM OF RAKING SHORES

Raking Shore or Raker.—A piece of timber sloping up from the sole-plate to the wall-piece and joined as in fig. 2. The top and longest shore may necessarily be formed in two pieces. The upper one is the *riding shore* or *rider,* and the lower, which supports it, is the *back shore.* At their junction folding wedges are introduced to give the head of the rider a firm bearing against the needle and wall-plate above. The *sole-piece* (fig. 2) usually consists of a piece of 11 by 3 plank, but may have to be bedded on a platform of timber to spread the weight over a large area. The sole should be placed at an angle (say 80°) with the inside of the shore to enable the latter to be gradually levered to a firm bearing with the aid of a crowbar. Wedging should not be resorted to or the building may sustain injury through vibration. When in position the foot of the shore is fixed by dog-irons to the sole-piece, and for additional security against slip, a cleat is spiked very firmly on the sole plate.

Braces.—Compound shores are stiffened and braced either by rough boarding nailed across them or bound with bands of hoop-iron (figs. 1 and 2). For further strength braces of 1-in. boards, 6 to 9 in. wide, are used to bind the shores and plate together. The *wall-plate* is usually a "deal" 9 in. wide by 2 in. thick, secured against the wall with wrought-iron wall hooks, forming a good abutment and serving to spread the pressure from the shores over a large area of the wall supported by them. Holes are cut through this plate to receive the *needles,* which are pieces of wood about 1 ft. long and 4 in. square in section, cut with a shoulder to butt against the wall-plate. A portion of a brick or stone is removed from the wall and the end of the needle is passed through the hole in the wall-plate into the recess in the wall. The head of the needle projects about $4\frac{1}{2}$ in. beyond the face of the wall-plate and forms an abutment for the notched head of the shore; the notching prevents side movement. A *cleat* is housed and spiked above the needle to obtain a firm bearing.

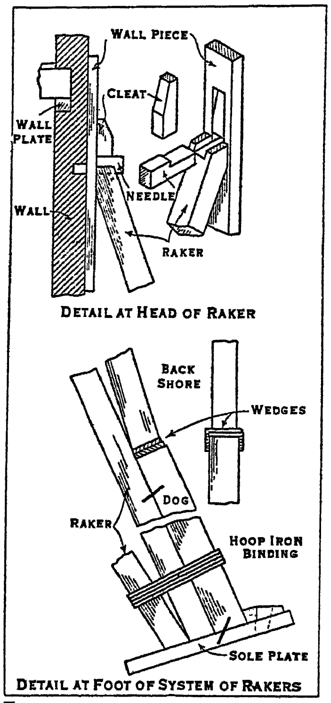

FIG. 2.—DETAILS OF JOINTS USED IN ASSEMBLING FIG. 1

Horizontal shores, or flying shores, may be employed for spans up to about 35 ft. They are used to support the party walls of buildings which adjoin premises being rebuilt. They are erected in stages during the pulling down operations and removed as the new building is raised. A system of flying shores consists of one or more horizontal timbers, sometimes known as dog shores, cut in tightly between wall-plates similar to those employed in raking shores (fig. 3). These horizontal members are supported at each end by cleats and needles fixed in the wall-plate and the shores are supported in their length by inclined struts springing from needles fixed near the lower ends of the wall-plates and serving to strut the shore at a point about a third of its length from the wall. Corresponding braces are carried from the upper surface of the shore and abut against needles at the upper ends of the plates. Straining pieces are secured to the upper and lower faces of the horizontal member to serve as abutments for the ends of the struts. The best angle for these struts is about 45°, but a smaller inclination has frequently to be adopted. Wedges are inserted, usually at the end of the *flyer* and sometimes between the struts and the straining piece, and gently driven to cause each timber to find a close bearing. If the adjoining premises are of considerable height and especially if it is proposed to undertake extensive excavations, the systems of flying shores may be complicated, each consisting of several horizontal members spaced from 10 to 13 ft. apart, placed opposite floors or other solid masses and well strutted one to another and to the wall-plate (fig. 4). The members should be securely dogged and spiked together to form a rigid framework able to resist the attacks of a strong wind.

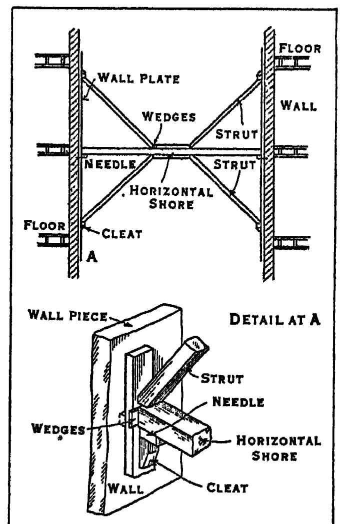

FIG. 3.—HORIZONTAL OR FLYING SHORE

Horizontal shores are preferable to raking shores. Besides being more economical, they are more convenient and more efficient than rakers springing from the ground, especially if the height of the building is considerable and the span not much over 30 ft. They present a direct resistance to the thrust and are well out of the way of building operations that may be carried on below them, so that there is little risk of their being accidentally disturbed; raking shores may be disturbed by accident or loosened by digging and other operations.

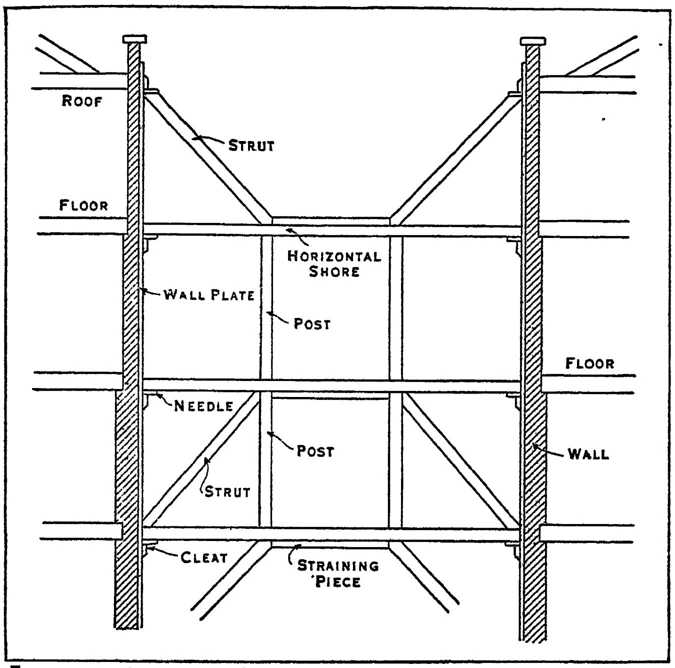

FIG. 4.—SYSTEM OF FLYING SHORES USED IN CONSTRUCTING A HIGH BUILDING

Dead shoring is also known as *vertical shoring* or *needle shoring*, and is adopted to support the upper portion of a building when necessary to reconstruct foundations or to make large openings in the lower parts of the wall, as, for example, when putting a shop front in an existing building. This form of shoring consists of horizontal members of balk timber or steel I-sections termed *needles* (very different from the needles used in raking and flying shoring), which are passed through holes in the wall to be supported, at a sufficient height to allow of the insertion of any arch or lintels that may be necessary above the proposed opening. The needles are supported at each end by an upright timber or *dead shore*, one on each side of the wall to each needle. These should not be allowed to rest upon any floor or vault but be carried down to a solid foundation and set upon and securely dogged to a timber sleeper running parallel to the wall. If it is not practicable to take the inner dead shore through intervening floors down to the solid ground in one piece, and it is necessary for its base to rest upon the floor or upon sleepers placed on the floor, the shores must be continued in a direct line below it until a firm foundation is obtained. Between the needle and the head (or base) of the dead shores folding wedges are inserted to force the horizontal supporting balk firmly up to the underside of the masonry. Fixings between dead shores, needles and sleepers are made with wrought iron dogs. The spacing of dead shores depends upon the material of the wall; for brickwork the intervals should not be greater than 6 ft. With this form of shoring it is often necessary to adopt supports auxiliary to the main shoring.

All openings in the wall above should be well strutted between their reveals to prevent any alteration of shape taking place. Inside the building, for support of the floors, vertical shores or strutting must be carried up independently from a firm foundation, in a direct line between the floors with head and sole plates at floor and ceiling to relieve the wall of weight from the floors and roof. To obviate settlement as much as possible, work done in underpinning should be built slowly with rich Portland cement mortar. Before the shoring is removed, at least a week should elapse to allow the work to set hard and firm. Then the needles should be carefully loosened and removed and the holes from which they were withdrawn made good. The remainder of the props can then be "struck," leaving the raking or flying shores until the last.

Rules and Sizes for Raking Shores.—Walls 15 ft. to 30 ft. high should have 2 shores to each system; if more than 30 ft. in height an additional shore is required for each increase of 10 ft. Shoring is rarely seen more than 5 shores high. The angle of the main shores is usually about 60° (but may be governed by local regulations concerning the use of the roadway), and none of the timbers should exceed an angle of 75° to the horizontal. Some of the lower shores will slope at angles between 40° and 60°. The systems should not be placed at a greater distance apart than 15 ft. and they should always be applied at the piers between window openings. The approximate section of a shore for any height of building may be determined by dividing the height of the building (at point of application) in feet, by five; then the result equals the side of the square section in inches.

For Horizontal or Flying Shores.—For spans not exceeding 15 ft. the principal strut may be 6 in. by 4 in., with raking struts 4 in. by 4 in.; for spans exceeding 15 ft. but not exceeding 35 ft. the size of the principal strut should be from 6 in. to 9 in. square, and the raking struts from 6 in. by 4 in. to 9 in. by 6 in.

The restoration of some important and ancient buildings in England by the British Office of Works has provided the opportunity for the design and application of new methods of shoring where great loads have had to be supported upon arcade arches while the original piers or columns were removed and restored.

The system adopted was to build very large brick piers under each arched opening and to construct brick rampant arches springing from each side of the pier and terminating against the soffits of the original arches thus providing pairs of side supports to each spandrel portion. As the arcade supported a high and thick wall, this latter was also shored by raking shores—with which was combined scaffolding for use in restoring the wall faces. The columns were provided with a steel core of special section, round which the original column facing was rebuilt.

The whole system was applied at Tintern abbey and at Furness abbey and met its purpose admirably. It is an excellent example of structural engineering applied to restoration work.

The principal works of reference on this subject are: C. H. Stock, *Shoring and Underpinning* (3rd ed., 1902); G. H. Blagrove, *Shoring and its Application* (1887); G. Ellis, *Modern Practical Carpentry* (1915).

SHORNCLIFFE, a military station in Kent, England, on high ground north of Sandgate and 3 m. W. of Folkestone.

SHORT, SIR FRANCIS JOB (1857–), knighted 1911, English engraver and water-colour painter, was born at Stourbridge, Worcestershire, on June 19, 1857. He was educated to be a civil engineer, and came to London in 1881 as assistant to Baldwin Latham in connection with the parliamentary inquiry into the pollution of the river Thames. He was elected an associate member of the Institute of Civil Engineers in 1883 and the same year joined the National Art training school, South Kensington, and worked at the Westminster school of art, and at the Schools of the Royal Institute of Painters in Water-colours. His real life-work now became that of an original and translator engraver. He was a keen student of the works of J. M. W. Turner; and his etchings and mezzotints from Turner's *Liber Studiorum* (1885 *seq.*), wonderful examples of devotion and skill, were among his earliest successes. Short also reproduced in fine mezzotints several of the pictures of G. F. Watts, and engravings of the landscapes of David Cox and Peter de Wint. His subtle drawing of the receding lines of the low banks and shallows of river estuaries and flat shores is seen to perfection in many of his original etchings, mezzotints, and aquatints.

Short was elected A.R.A. in 1906 when the rank of associate-engraver was revived. As head of the Engraving school at the Royal college of art, South Kensington, he had great influence on younger engravers. He was elected to the Royal Society of

Painter-Etchers and Engravers in 1885. In 1910 he succeeded Sir Seymour Haden as president.

See *The Etched and Engraved Work of Frank Short,* by Edward F. Strange (1908), which describes 285 plates by the artist.

SHORTER, CLEMENT KING (1857–1926), English journalist and author, was born in London on July 19, 1857. After working as a clerk at Somerset House, he became a journalist on the staff of the *Penny Illustrated* in 1890. He was editor of the *Illustrated London News* from 1891 to 1900, and founded and edited the weekly *Sketch* (1893), the *Sphere* (1900) and the *Tatler* (1903). He helped to found the Omar Khayyam Club, and was at one time president of the Johnson Club. He was a considerable critic and literary historian, and was interested particularly in Borrow, Dr. Johnson and the Brontës. He died on Nov. 19, 1926, leaving a valuable collection of books and manuscripts. Shorter's first wife, Dora Sigerson, is separately noticed.

In 1896 he published *Charlotte Brontë and her Circle,* and later edited the Haworth edition of the Brontës with Mrs. Humphrey Ward. In 1924 he issued a private edition of Patrick Branwell Brontë's *And the Weary are at Rest.* He edited Boswell's *Life of Dr. Johnson* (1922) and Mrs. Gaskell's *Life of Charlotte Brontë.* Through various connections of the Brontë family, a number of unpublished documents came into his possession, and he privately printed over 30 brochures on the Brontës and other subjects, including Mrs. Gaskell's *My Diary; the early years of my Daughter Marianne.*

SHORTHAND is the art of writing legibly, by means of brief signs, at a rate sufficiently rapid to record speech. It has been variously known as stenography (close, little or narrow writing), tachygraphy (swift writing), brachygraphy (short writing). But the term "shorthand" is now almost universally applied to it. Shorthand is now employed widely in reporting the proceedings of parliament and legislative bodies, the trial of cases in courts of law and especially for taking dictated business correspondence, reports and other business communications.

The Shorthand of the Ancients.—The earliest record we have of an organized system of shorthand dates from the year 63 B.C., the age of eloquence in Rome. At that time a freedman and friend of Cicero, Marcus Tullius Tiro, invented a system of *notae* that was used in recording the speeches of Cicero, Seneca and others of the Roman senate. The system invented by Tiro was taught in the Roman schools, was learned by emperors, and remained in use for several centuries. We are informed by Plutarch, in his life of Cato the younger, that the speeches of Caesar and Cato in connection with the conspiracy of Catiline were taken down verbatim by *notarii* who had been placed by Cicero in various parts of the Senate.

An inscription on a marble slab from the Acropolis at Athens, attributed to the 4th century B.C., indicates that a system of brief writing was practiced among the Greeks. Tiro's system was based on the orthographical principle; it abounded in the use of initials, following in this respect the abbreviating formulae in common use with the Romans; and, principal distinction of all, it was marked by this peculiar excellence which renders it superior to every other system known till to-day—namely, that by it, one and the same consonant letter, without the addition of points or any other signs whatsoever, expressed, by the inclination of such letter in three different directions, the exact vowel, *a*, *e*, or *i*, which followed. In the case of some of the consonants the whole five vowels, and even the diphthongs, were capable of like indication.

Example of Tironian Notae:

Nemo fideliter diligit quem fastidit nam et calamitas querula

Shorthand in the Middle Ages.—After the fall of the Roman empire, the use of the Tironian system survived for several centuries. In A.D. 625 Tironian notes were used in the royal diploma of the Merovingian King Clotaire II. In subsequent years we find on public documents brief notations as to the composition of deeds, names of officials concerned, etc. It is the opinion of some authorities that such notations were a protection against forgery. Examples of Greek shorthand are confined to a few fragmentary papyri and waxen tablets ranging from the 4th to the 8th century, chiefly among the Rainer collection at Vienna to which Prof. Wessely has devoted much labour. A manuscript (Add. ms. 18231) in the British Museum contains marginal notes in shorthand of the date A.D. 972 (Wattenb., *Script. Graec. specim.*, tab. 19). Dating from the 10th century, we find the Paris ms. of Hermogenes, with some tachygraphic writing of that period which Bernard de Montfaucon deciphered with incredible labour (*Pal. Gr.*, p. 351). But the largest amount of material is found in the Vatican ms. 1809, a volume in which as many as 47 pages are covered with tachygraphic writing of the 11th century. Cardinal Angelo Mai first published a specimen of it in his *Scriptorum veterum nova collectio* (1832); and in his *Novae patrum bibliothecae tom. secundus* (1844) he gave a second, which, in the form of a marginal note, contained a fragment of the book of Enoch.

Shorthand and the Early Christian Church.—With the rise of the Christian Church and a demand for the exact utterances of the religious leaders of the day, the teaching and practice of the Tironian *Notae* received a new impetus. Many of the trials of the early Christians were reported by shorthand writers who were employed by the church for that purpose.

Revival of Shorthand in England.—England was the birthplace of modern shorthand. The publication by Dr. Timothy Bright in 1588 of his *Charac erie: an Arte of Shorte, Swifte, and Secrete Writing by Character* marked the beginning of this development in England. Bright's system was invented during the reign of Queen Elizabeth and dedicated to her. It provided that each sign could be given four different slopes, and that the base of each could be modified by 12 varying terminations.

With the publication of the *Arte of Stenographie* in 1602 by John Willis began the introduction of the systems based on the alphabet. These systems are sometimes referred to as orthographic, because they followed the spelling of the words, omitting silent letters and in many cases the vowels in a word. One of the best known of these orthographic systems is that of Thomas Shelton, published about 1630, in which the famous diary of Samuel Pepys was kept. In 1767, Dr. John Byrom published his *Universal English Shorthand.* His principal contribution to the art was greater lineality in writing, and representation of the five vowels by writing a dot in five different positions with respect to the consonant outline. His system was popularized by Thomas Molyneux, who published seven cheap editions between 1793 and 1825. In 1786, Samuel Taylor published in London an *Essay Intended to Establish a Standard for a Universal System of Stenography.* He simplified his system considerably by limiting each letter to one sign, except *w*, and by the elimination of a great many of the arbitrary signs that had characterized previous systems. His system was eventually adapted for use in France, Italy, Holland, Sweden, Germany and other Continental countries.

Development of Phonetic Shorthand.—Most of the early systems of shorthand in England were orthographic or alphabetic, but the idea of writing according to sound continued to gain in favour. The first published system using a phonetic base was that of William Tiffin (1750). Others were Lyle (1762), Holdsworth and Aldridge (1766), Roe (1802), Phineas Bailey (1819), Towndrow (1831) and De Stains (1839).

PITMAN SYSTEM

The publication by Isaac Pitman, in 1837, of *Stenographic Sound Hand* marked a new era in the development of phonetic systems. Not only did he classify the sounds of the language scientifically and arrange his material for writing accordingly, but he introduced simple expedients of abbreviation that made for rapidity. A short summary of the principles underlying the system is given.

Since the system is phonetic, all words are written according

to their sounds. The words *lain, deal, may, knife* would therefore be written as if they were spelled *lān, dēl, mā, nīf*.

PITMAN'S SHORTHAND ALPHABET

CONSONANTS

Names		Sign	Names		Sign	Names		Sign	Names		Sign

1. AH	1. AW	ă	ŏ
2. EH	2. OH	ĕ	ŭ
3. EE	3. OO	ĭ	ŏŏ

DIPHTHONGS

I OI OW U

Consonants.—The consonants in the system are drawn from simple geometrical forms, straight lines and shallow curves. It is a curious fact that, while the tendency in longhand writing, beginning about A.D. 600 with the development of the Uncial letters, was away from the Roman capital letters and toward a cursive style, this tendency did not affect shorthand writing, although several systems appearing before Pitman's were cursive in form. In Pitman's system there are 26 signs for 24 consonant sounds in the language, two of the signs being provided with duplicates for convenience in joining with other signs. The first 16 signs occur in pairs, a light sign for a light sound, and a heavier sign for a heavy sound.

Vowels.—The 12 vowels in the language, *ah, a, e, aw, o, oo,* as heard in the words, "Pa, may we all go too?" and their corresponding light sounds, *a, e, i, o, u, oo,* as in the words, "That pen is not much good," are represented by a dot and a dash, disjoined. A heavy dot placed opposite the beginning of a consonant represents the long vowel *ah;* opposite the middle of the stroke it represents *ā;* and opposite the end of a stroke it represents *ē.* A short, heavy dash placed similarly represents the sounds *aw, ō, ōō.* The dot or the dash is made very light to represent the corresponding light or short vowel sounds. To illustrate: pa bay tea sigh ode bug

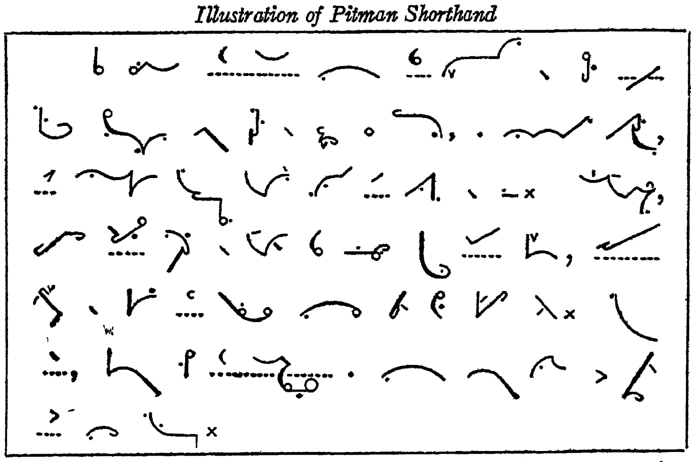
The sound *s* when preceding or following another consonant is expressed by a small circle: pays tease spy spouse. When the sound *ses* occurs other than at the beginning of a word, it is represented by a large circle: paces teases spices excessive. When the large circle is the beginning of a consonant it represents *sw:* swoop Swede swim. The small circle for *s* is turned into a small loop to represent *st,* and into a larger loop to represent *str:* past pastor boast boaster must muster state steam.

Use of Hooks.—The hooks used as abbreviating devices are obtained from segments of the circle *s,* or of the large circle for *ses.* A small hook written at the beginning of a consonant on the left of straight downstrokes and under horizontal strokes adds *r;* a small hook written at the end of a consonant under the same conditions represents *n:* pray brain tray train grow grown. A small initial hook written on the right side of downstrokes or above horizontals represents *l;* at the end of these strokes, it expresses *f* or *v:* play pave brave blow bluff glow glove. The common sound of *shun,* no matter how it is spelled, is expressed by a large hook: passion petition occasion. When used with curved letters, the hooks are always written inside the curve. The small hook represents *r* at the beginning of a stroke and *n* at the end of a stroke: frayed fan fans loan. A large hook at the beginning of a curve adds *l* and at the end of a curve it adds *shun:* flow flung evil notion motion. The halving of a stroke indicates the addition of *t* or *d.* This principle is of great value in writing the past-tense forms of verbs: float floated plate plated pain pained or paint grade graded label labelled. Doubling the length of a consonant adds *ter, der* or *ther:* track tractor laugh laughter bill builder mole moulder pore porter.

Vowel Indication.—In rapid writing it is not possible to insert all vowels, nor is it necessary. Three methods are employed to indicate the presence or absence of a vowel. Letters having alternate forms are used for this purpose; the downward *r* usually indicates that a vowel precedes it, whereas the upward form is usually used when a vowel follows. By writing a word in position with relation to the line, it is possible to indicate a vowel. Words may be written above the line to indicate a first-place vowel, on the line for a second-place vowel, and through the line for a third-place vowel. The first up or down stroke in the word generally takes the position, and the rest of the outline follows in regular order. The position of the word is determined by the first vowel. The third method of vowel indication is by the use of some of the consonant outlines instead of their abbreviated form, as the use of the *s* stroke in place of the circle at the beginning of a word, or the writing of the *n* stroke in place of the *n* hook in such a word as *funny.*

Grammalogues.—A large number of the most commonly occurring words have been condensed in outline form so that they can be written with one stroke of the pen without vocalization. These words are memorized and learned thoroughly so that they can be written with great facility. Illustrations: that is as, has are our it should cannot you this. Just as the early authors discovered that joining words increased the speed of writing, so Pitman's system affords an extensive use of this principle of phrasing: you cannot you cannot be. Besides the list of grammalogues, there is a list of contractions which it is necessary for the writer

Illustration of Pitman Shorthand



It is certain that any matter that is likely to strain our attention severely should be attended to when the mind is clear, the memory retentive, and the mental faculties fully alert and ready to act. Unfortunately, we cannot always arrange to follow this excellent division of our time, and we are obliged to deal with business matters just as they turn up. After all, it may be said that in all these cases the matter may be left to the judgment of the man affected.

to memorize before he can develop much speed. These contractions are usually long or awkward outlines that have been reduced in form by dropping parts of the word but at the same time keeping them significant enough to establish their identity.

Examples of these are: indispensable dangerous indefatigable

The Pitman system was introduced into America a few years after its publication. Alfred Baker tells us in the *Life of Sir Isaac Pitman* that the first instruction book in Pitman shorthand was brought out by Mr. Stephen Pearl Andrews (Boston, 1844). In 1852, Mr. Benn Pitman, brother of the author of the system, came to America to continue the work he had been doing for several years. After the publication of the 10th ed., in which the vowel scale was changed, Benn Pitman refused to adopt the change and adhered to the old forms. Many others who had learned and practised the system began to modify it and publish it in altered form. Among these were A. J. Graham, J. E. Munson, E. Longley and Eliza B. Burns.

Script Systems.—Just as Pitman and his predecessors rejected the orthographic principle in shorthand and adopted the phonetic basis, so another group of authors discarded the use of geometrical signs. As early as 1787, S. G. Bordley had presented his cursive shorthand. This was followed by R. Roe (1802), T. Oxley (1816), J. and J. Aitchison (1832) and D. Cadman (1835). In France and Germany script systems had been introduced successfully and are in wide use to-day. Fayet's French system and Gabelsberger's German system are illustrations.

GREGG SYSTEM

In 1888, John Robert Gregg published his Light-Line Phonography, in which he incorporated what he considered this fundamental idea of employing shorthand characters that were in harmony with the slant and movement of longhand as well as many other principles, the lack of which had given rise to many criticisms of existing systems. Gregg adopted the phonetic principle and added a scientific analysis of *handwriting*. The title of the first book of his system was *The Phonetic Handwriting*. Gregg brought his system to America and offered it to the public soon after its publication in England. At present it is taught in more schools in the United States, and practised by more stenographers, than any other. A summary of the system is presented. The basic principles given below are taken from a copy of the original Light-Line Phonography, published in 1888: (1) Total absence of shading or thickening. (2) The characters being based on the elements of the ordinary longhand, the strokes are familiar and the motion uniform. (3) The insertion of the vowels in their natural order without lifting the pen. (4) The absence of positions, or the placing of words on, above, or through the line of writing to imply the omission of certain vowels or consonants. (5) The preponderance of curve motion.

Although some changes have been made in the system since 1888, these principles have remained the same.

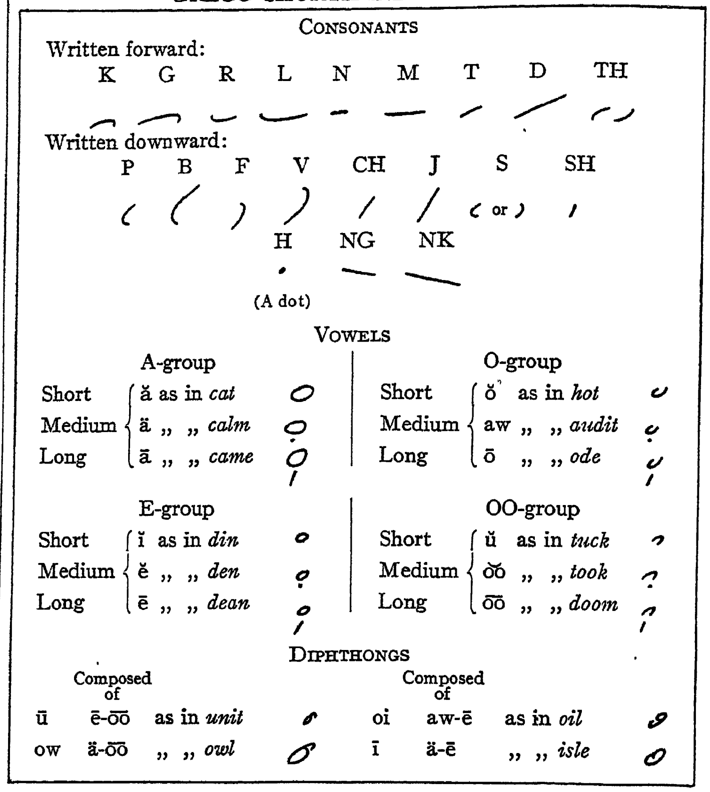
Consonants.—The consonants generally are paired according to affinity of sound and are distinguished by length. Consonant signs were selected which would permit the joining of many frequently recurring consonantal combinations without modifying the primitive form and to make possible the writing of these forms with but one movement of the pen, thus: pr br

pl bl kr kl gr gl

The Signs for S and Th.—To facilitate joining in various combinations alternative signs are provided for the frequently recurring sound of *s*, written downward, and for *th*, written upward. In the use of these forms two principles serve as guides: uniformity of rotation and forward movement when joined to curves; sharp angles when joined to straight strokes.

Vowel Signs.—The vowels are expressed by circles, small and

GREGG SHORTHAND ALPHABET



large, and by hooks. A small circle expresses the E-group of vowels, *ĭ, ĕ, ē;* a large circle, the A-group, *ă, ä, ā.* The circle is written on the inside of curves and on the outside of angles; before and after straight strokes, or between straight strokes in the same direction the circle is written clockwise; between reverse curves the circle is turned back on the first curve. A system of diacritics is provided for showing the exact shade of sound, as for example *ă, ä, ā,* but since the large circle expresses an *a*-sound in any case, the need for these diacritics arises rarely. To illustrate the application of the rules for joining circles: key air meet gain make aim me mean wreck lake The hook vowels are derived from a small elliptical figure, thus: the lower part expressing the O-group of vowels, *ŏ, aw, ō;* the upper part expressing the OO-group, *ŭ, ŏŏ, ōō.* These hooks join naturally in most combinations but they are modified in two instances to avoid unnecessary angles, thus: the O-hook is turned on its side before *n, m, r, l;* the OO-hook is turned on its side after *n, m,* and after *k, g,* if followed by *r* or *l.* Illustrations: ought wrote know shop obey to foot mode mood cull coal on nor

Signs for W and Y.—*W* has the sound of *ōō,* as *ōō-ā-t* in *wait,* and is expressed by the sign for *ōō. W* within a word is expressed by a short dash struck under the vowel sign. The sound for *y* is equivalent to long *e,* as *ē-ōō-th* in *youth,* and is so expressed, except *ye* is expressed by a small loop, and *ya* by a large loop. Illustrations: wait weave youth yacht yellow Yale queen

Diphthongs.—The signs for the four pure diphthongs, *ū, ow, oi,*

i, are written by simply joining the signs for the sounds composing them. Concurrent vowels are written in the same way. Illustrations: feud now toil try price science enjoy radio

Blended Consonants.—When two straight lines form an obtuse or blunt angle the natural tendency of the hand is to slur the angle and allow the lines to form a curve, thus

This principle is applied in securing a number of frequently recurring syllable signs:

TEN, DEN	*as in* tenor		denote	
TEM, DEM	*as in* temper		demolish	
ENT, END	*as in* paint		bond	
EMT, EMD	*as in* prompt		deemed	
DEF-V, TIVE	*as in* defeat		native	
JENT-D, PENT-D	*as in* gentle		happened	
MEN, MEM	*as in* mention		memory	
TED, DED, DET	*as in* heated		seated	
SES	*as in* passes		faces	
XES	*as in* boxes		mixes	

Expressing R.—By writing the circle with a reverse movement before or after straight lines; between a horizontal and an upward character; between a downward character and *t*, *d*, *n*, *m*, the sound *r* following the circle is expressed. Illustrations:

art share yard tardy
barn chart earn cart

Wordsigns and Phrases.—The Gregg system includes a list of forms, called wordsigns, for the commonest words of the language which are reduced to the simplest outlines. Examples: the of and a-an in-not that at-it is-his I

These words, through repetition, comprise more than one-quarter of all written and spoken English.

Phrasing.—Phrasing forms a very important function in the Gregg system. Since the words do not depend on position for vowel indication, phrasing is limited only by whether or not outlines can be joined easily. The following phrases will show how the principle is applied to wordsigns: of the that the it is in the in that and in

General Abbreviating Principle.—The rule for abbreviation given in the first edition of *Light-Line Phonography* remains the same to-day. It reads, "Drop the termination of words, *i.e.*, write so much of the outline as will, with the aid of the subject matter and vocalized context, suggest the whole word, as *unan* for *unanimous*, etc." This principle is already familiar in longhand, as *Rev.* for *Reverend*, *Ans.* for *answer*, *Jan.* for *January*, *Phila.* for *Philadelphia*, etc. Illustration:

It is *pos*sible that the *suc*cess of the *mag*azine may make it

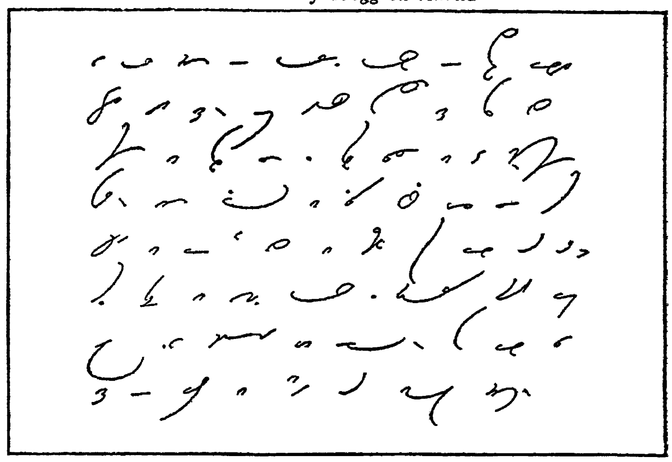
*neces*sary to change the *pol*icy of the *asso*ciation at the next

meeting at *Phila*delphia.

The principle is applied generally to long words not taking regular suffix endings. Its application gives brief and legible word-forms for a large number of words.

Prefixes and Suffixes.—The system is provided with joined and disjoined prefixes and suffixes, built up on the principle of analogy, for the most part, thus: forgive submit parallel overthrow going fairly nation common envy impress express proper

Illustration of Gregg Shorthand



The real success in learning lies in absolute honesty particularly to yourself. Never try to make yourself believe that you have done your best when a voice within you says you should have done better. You can hold your head high only when you have satisfied your own self that your efforts have been honest and thorough. Having chosen your calling, lay a solid foundation on which to build the structure of your knowledge. Be honest with yourself in whatever you undertake, and you will be successful.

Conclusion.—Expert writing of shorthand has been recognized in some States as a profession; the Department of Education of the State of New York conducts an annual examination and awards to those successful in passing the test the degree of C. S. R. (certified shorthand reporter). From 1909 to 1927, the National Shorthand Reporters' Association conducted an annual speed contest consisting of three five-minute dictations on different classes of matter. Records have been established of 280.4 words a minute on court testimony (Charles L. Swem); 259.6 words a minute on judge's charge to the jury (Martin J. Dupraw); and 220 words a minute on straight literary matter (Martin J. Dupraw, Nathan Behrin, Solomon Powsner), the degree of accuracy attained in all cases being greater than 99%.

(E. J. McN.)

SHORTHOUSE, JOSEPH HENRY (1834–1903), English novelist, was born in Great Charles Street, Birmingham, on Sept. 9, 1834, of Quaker parents. Shorthouse wrote his famous story, *John Inglesant*, when he was forty; he finished it in 1876, and after keeping it for three years in ms. printed 100 copies (1880), one of which came into the hands of Mrs. Humphry Ward, who recommended it to Messrs. Macmillan, but Gladstone

was at once struck by its quality, and made its reputation by his praise. It became the most discussed book of the day, and its author was suddenly famous. Besides *John Inglesant* (1881), Shorthouse published other novels, none of which had the same success. In 1861 he joined the Church of England. Something of his own stress of religious transition appears in the character of his hero. Shorthouse died at Edgbaston on March 4, 1903.

See *The Life, Letters and Literary Remains of J. Henry Shorthouse,* edited by his wife (2 vols., 1905); E. Gosse, *Portraits and Sketches* (1912).

SHORT STORY, THE. It is possible to distinguish between three forms of fiction—the novel (*roman*), the novelette (*nouvelle*) and the short story (*conte*). The difference between the first and second form is a matter of quantity rather than quality: as may be deduced from a comparison of, say, *Kim,* which is a novel, and *The Light That Failed,* which is a novelette. The modern tendency among writers of fiction is to shorten the novel to a novelette, and a stricter sense of art is here at work; a more intensive method of narration, not a less extensive view of men and matters being the compelling motive. The necessity for condensation and the exclusion of passages which have no direct bearing on the plot and characterization, if the attention of a modern reader is to be gripped, has been emphasized by writers as different, nay divergent, in their matter and manner as Merimée, Turgeniev, Stevenson and Kipling, the last-named of whom declared that "the three volume novel is extinct," in the motto prefixed to the literary requiem entitled "The Three-Decker." But the tendency has not proceeded so far that the novelette must be considered a different species from the novel. Moreover there are signs of a reaction in favour of the long, discursive novel in the popularity of William de Morgan's leisurely rambling stories, in the success of Dorothy Richardson's long, analytical studies of motive, and James Joyce's *Ulysses,* which might be described as a three-decker with the Freudian philosophy for ballast.

Totality.—The short story, however, differs from the novel and the novelette, not only in length and size of canvas, but also in its aim and nature. In his famous review of Nathaniel Hawthorne's *Tales* (1842) Poe, the first great master of the modern short story, outlined his theory of the tale that has the force of "totality," which a long novel, not to be read at one sitting, cannot possibly possess:—"In the whole composition there should be no word written, of which the tendency, direct or indirect, is not to the one pre-established design. . . . The idea of the tale has been presented unblemished, because undisturbed; and this is an end unattainable by the novel. Undue brevity is just as exceptionable here as in the poem; but undue length is yet more to be avoided."

The influence of Poe's short stories was immense, particularly in France, but his critical theory was not generally received until 40 years later when Brander Matthews published his well-known essay on "The Philosophy of the Short-Story." In the second part of his essay he summarizes his argument as follows:—"A true short-story is something other and something more than a mere story which is short. A true short-story differs from the novel chiefly in its essential unity of impression. In a far more exact and precise use of the word, a short-story has unity as a novel cannot have it. Often, it may be noted by the way, the short-story fulfils the three unities of the French classic drama; it shows one action, in one place, on one day. A short-story deals with a single character, a single event, a single emotion, or the series of emotions called forth by a single situation."

It may be added that, to achieve "totality" or unity of impression in the highest degree, the short story must be an organic whole. This point is emphasized in a letter written by Stevenson to Sir Sidney Colvin, who had suggested that he should change the end of one of his tales:—"Make another end to it? Ah, yes, but that's not the way I write; the tale is implied; I never use an effect when I can help it, unless it proposes the effects that are to follow; that's what a story consists in. To make another end, that is to make the beginning all wrong. The *dénouement* of a long story is nothing, it is just a 'full close,' which you may approach and accomplish as you please—it is a coda, not an essential member in the rhythm; but the body and end of a short story is bone of the bone and blood of the blood of the beginning."

Brevity.—Brevity, which comes of the artistic desire for the greatest possible economy of means, is not an essential characteristic of the short story. There are many long short stories, of which the most famous are *The Turn of the Screw,* by Henry James (which runs to something like 40,000 words). Stevenson's *Dr. Jekyll and Mr. Hyde,* and *The Man Without a Country* by Edward Everett Hale. One of Dorothy Richardson's full-length novels was once added to the list of long short stories by a facetious critic on the score that it was "about a quarter of an hour!" On the other hand a very brief tale may not possess that organic unity which would justify us in calling it a true short story.

Conscious Unity.—The short story has always existed, though it was not until the 19th century that the art of writing it was consciously practised. As Sophocles said of Aeschylus, these early authors of short stories did the right thing without knowing why. It was only on rare occasions, however, that these happy accidents occurred. Thus Professor Baldwin, after an exhaustive and rather exhausting examination of the hundred tales in Boccaccio's *Decameron,* decided that only two of them—the second story of the second day, and the sixth of the ninth day—are short stories in the modern critical sense, while three others approach the "totality" of impression which is the result of conscious unity in expression. We must go back to the New Testament for a short story which is a structural masterpiece. There can be no denying that the parable of the Prodigal Son, which is only 500 words long in the noble prose of the Authorised Version, satisfies the modern definition, securing the greatest emphasis possible with a surprising economy of means. Setting aside the religious implications of the story and treating it as a single narrative effort, we have to admit that its theme is profoundly interesting, that its three characters are perfectly portrayed, and that it is informed with a complete knowledge of human nature. The reiteration of the beautiful words of compassion and reconciliation: "For this thy brother was dead and is alive again; and was lost and is found" is a stroke of divine artistic genius which completes the whole prearranged design. The parable suggests a gold coin or medal which has been created by a single impact of the die, and it rings true because it is of noble metal nobly wrought. It owes much, no doubt, to the grave simplicity of its style (less than half-a-dozen words in the narrative are of more than two syllables) and this fact should serve to remind us that nearly all fine great short stories in the English language have a distinction of style which measures and maintains the emotional significance of the theme.

The same author has seldom, if ever, been able to write great short stories as well as great novels. Scott's *Wandering Willie's Tale* and Dickens' *A Child's Dream of a Star* are notable exceptions to this rule. Poe, Maupassant, Bret Harte, G. W. Cable, O. Henry, to name a few of the masters of the short story, could not have written great novels—perhaps because the minute exactness and restriction of structure required for success in the short story create a mentality which cannot give us cross-sections through the vast body of human life or trace its bewildering intricacies. The painter of miniatures, if we may risk a comparison from another art, cannot hope to be successful in work on a large canvas.

Poe and Maupassant.—Poe, whose mathematical mind could give a lucid explanation of the how and why of his artistic achievements, was really the ruling influence with Maupassant and other much-imitated French masters of the *conte,* which in their hands so often became a psychological epigram—with a sting, or perhaps a pang, in its conclusion. Nearly all these French story-writers were pessimists, as many of the French masters of aphorisms were, in their view of human nature, and they set their small self-contained dramas against a gloomy background of man's moral turpitude. *Boule de Suif* is perhaps the most powerful example of this cruel criticism of life, and it does grave injustice to the French character which is so kindly and considerate, even

among the *bourgeoisie*, to the courtesan. Anatole France's *Crainquebille* is one of the last large achievements in this mode, which has gone out of fashion since victory in the World War cured the French nation of its inferiority complex. Maupassant, however, will always remain a model of technique, especially for the young writer who suffers from the melancholy which is the shadow of youth's hopefulness.

Kipling.—Kipling, however, has had a more far-reaching influence in the development of the short story, and even those who have come to dislike his philosophy of life, largely as a result of post-war disillusionment, have adopted and adopt his technique, as a rule without admitting their indebtedness, even to themselves. Nine-tenths of the huge output of American short stories to-day might be described as acts of faith in the literary creed: "There is only one Kipling and O. Henry is his prophet." O. Henry, who is faithfully imitated by at least nine in every ten contributors to the American magazines, copied most of Kipling's mannerisms and has made a feature of the expository opening, which is so often used in *Plain Tales from The Hills* and the volumes that followed it in the next few years. It is a popular, but inartistic expedient, which may be compared with the informative soliloquy of the old family servitor in pre-Ibsenite comedies. The younger school of writers reject it, knowing that it is much more effective to convey such information implicitly, through the words and works of the characters, which has the added advantage of not subverting the narrative form. In his later short stories, such as the admirable *They* and *The Brushwood Boy,* the English master has avoided it, nor has he committed the technical blunder (it occurs more than once in the "Plain Tales") of adding superfluous matter when his story is logically complete—a blunder perpetrated by O. Henry in *The Gift of the Magi,* perhaps the most famous of all his stories.

The Russians.—To-day the Russians, especially Chekov and Kuprin, whose *Captain Ribnekov* is one of the best short stories in any language, are the dominating influence with the youngest writers. Since the Slav genius, with its abiding sense of *prostor,* or illimitable horizons, has no liking for such limitations, some of them are in rebellion against the doctrine of unity.

Post-War Stories.—Since the World War ended—to be transferred to the spiritual sphere as a campaign against all manner of conventions—the output of short stories has greatly increased. They appeal strongly to minds too restless and preoccupied to read the old go-as-you-please novels or even the artistically composed and concentrated novelettes. At a rough estimate 100,000 short stories, good, bad and indifferent, have appeared in the last ten years, and it is manifestly impossible to make a critical survey of this vast mass of printed matter. Every type of periodical likes to publish short stories—especially the kind that "lies under the edge of the news"—and it is surprising how high the standard of craftsmanship is in these ephemeral productions. Since, however, they must take the orthodox view of life, including the happy ending, hardly one in a score awakens a second thought. The best of them may be compared with those local French soups, never seen on a hotel menu, of which the cook says: *Ça aide à faire passer le pain.* They help to carry off the news, which is so apt to be more indigestible than fiction.

The Regional Short Story.—The "regional" short story has never been as popular in England as in America and France, and the English public seems to be interested only in the dialect and local life of certain favoured areas, such as "Wessex," Cornwall and Yorkshire, though now and again a specialist in the short story, which is often a personality sketch, goes further afield and yet finds readers—S. L. Bensusan in East Anglia is a case in point. The best writers of the short story in England are generalists, so to speak, who find their themes in the town and countryside. There is a marked tendency among the younger authors to ignore the doctrine of concentration which insists that only one of the three threads—setting, plot and characterization—should be made prominent. Others, again, reject the dogma of unity since they find it does not exist in real life, and their stories are often presentations of a corner of the chaos of luxury, as viewed through a temperament. It is too soon to say whether a new form or forms will come into being and be established as a result of this rebellion against tradition.

Modern Writers.—Katherine Mansfield, who sought truth and found beauty by the way, is one of the inspiring influences which is revitalizing the short story to-day. Her noble supplication "May I be found worthy to do it! Lord, model me crystal clear for Thy light to shine through" was granted to such an extent that her best stories, such as *Ma Parker* and *The Doll's House* are illuminated throughout by a serene glow of comprehension. She, like most of the writers she has influenced by her notable achievement and still more noble promise, holds that form was made for the artist, not the artist for form. Other sincere artists, whose work will survive, are C. E. Montague (his *Fiery Particles* is a triumph), Miss Tennyson Jesse, Stacy Aumônier, Neil Lyons, Aldous Huxley and Princess Bibesco. But A. E. Coppard is perhaps the finest of all these young and sincere artists, who refuse to sacrifice truth to a beautiful epigram or to fall over the slippery verge of sentimentality. His style, beguiling and yet bewildering, is a new wine that creates its own new bottles, and he—and perhaps the same may be said of Princess Bibesco, whose lucidity is that of diamonds, which are not meant to be seen through—is the most original and provocative English writer of short stories at the present moment. (E. B. O.)

THE UNITED STATES

The short story, as it is now defined,—brief prose fiction with limitations and laws that make of it a distinct literary form—had its beginning in America in the *Sketch Book* of Washington Irving. Before 1819 there had been short fiction,—an abundance of it: the tale in prose and verse is in all languages one of the most abundant varieties of literature, but Irving was the first to recognize that it could be moulded into a prose literary form that would have laws and an individuality of its own.

The causes that led Irving as a pioneer into this field were three. (1) He had been stranded in England without funds, and he knew of no source of income for himself save through some variety of literary creation; (2) temperamentally he was fitted only for short dashes at literature; a novel, as he later abundantly proved, was not within his powers; (3) he realized that to succeed he must offer something distinctly his own. The popular literary form of the time was the romantic tale, told in verse after the Scott-Byron patterns or else in prose after the fashion of the German *märchen,*—tales of terror, ultra-romantic and often ultra-sentimental. Irving, intent upon originality, evolved the "sketch" as he called it. First of all, it was to be a thing for entertainment only, with no touch in it of the Addison-Steele-Goldsmith moralizing. Then, too, it was to descend from the general to the particular. He was not to deal with types but with individuals and individual localities. With no attempt at plot or dramatic action, he would induce in the reader a mood, an emotion: he would create an atmosphere. The short story was to be the frame on which he was to hang his materials; the materials were the all-important things. The difficulties attendant upon the creation of this variety of narrative as compared with the ease of writing the looser form of the novel he made clear in a letter to Brevort: he was the first to recognize, therefore, the short story as a distinct form. That he had evolved such a form he never once doubted. "I choose to take a line of writing peculiar to myself rather than to fall into the manner or school of any other writer," he wrote to a friend. "It is true other writers have crowded into the same branch of literature, and I now begin to find myself elbowed by men who have followed my footsteps; but at any rate I have had the merit of adopting a line for myself, instead of following others."

THE FORCE OF IRVING'S EXAMPLE

The influence of Irving was immediate and wide-spread. His great European success stimulated the group of young writers that, as we see it now, was to become the most distinctive in American literary history. A veritable epidemic of sketch-writing was the result. But there was no outlet for these sketches. The magazines were few and they paid nothing. At this critical moment, however, there came what must be denominated the second step in the evolu-

tion of the American short story: in 1826 was issued in Philadelphia the first number of an annual, or gift-book, *The Atlantic Souvenir*, soon to be followed in Boston by *The Token*, and then by others in all directions, literally by the hundreds. These annuals prided themselves on their American contents; they were illustrated with American-made steel engravings and filled with American poetry and prose. They sold large editions, and as a result they were able to pay contributors and thus become the source of nourishment for the first group of writers—Catherine Sedgwick, Paulding, Simms, Hawthorne, Poe and others. To *The Token* Hawthorne was able to sell no less than 24 of his "Twice-Told Tales," as he later called them.

A direct result of the great success of the annuals came in 1830 with *Godey's Lady's Book* which may be described as a monthly gift book. It specialized in short fiction, ruling from its columns all continued stories. Its phenomenal success, especially after it had called as its editor Sarah Josepha Hale, brought a host of imitators. Soon the age of magazines had opened in America—*Burton's, Peterson's, The Gentleman's, Graham's, Sartain's* and the like, all of them eager for original and well-written single-number pieces of fiction. It was Poe's contention that the short story was the child of the American magazine.

Another element helped in the evolution of the shortened form: the lack of international copyright laws. So long as it was possible for American publishers to secure for nothing their pick from the current fiction of England, they were in no haste to pay obscure American writers for their questionable products. In the mid-century Willis complained bitterly that he was forced to write short pieces instead of novels: "We must either write books to give away, or take some vein of literature where the competition is more equal—an alternative that makes almost all American authors mere contributors of short papers to periodicals."

Nathaniel Hawthorne.—After Irving the second important figure in the history of the short story was Nathaniel Hawthorne, who made of the form the study of a single intense situation often allegorical in its setting. He deepened the current of the short story and made it respected as a serious art form—he gave it beauty of style; and he perfected for it an artistry that called forth the praise of Poe. It was while reviewing the 1842 edition of *Twice-Told Tales* that Poe awoke to the conception of the "prose tale" as a distinct literary form, and he proceeded to formulate the laws governing it—a remarkable piece of criticism, the first codification ever attempted of short-story laws. The tale, he ruled, should be what one could read at a sitting. It must have singleness of aim, unity of tone from the first sentence, originality, compression, picturing power and "truth."

Poe.—Poe doubtless was thinking as much of his own artistry as he was of Hawthorne's. The review with scarcely a change could serve as an introduction to his *Tales of the Grotesque and Arabesque*. He had begun as a prose-writer by making travesties of the conventional short fiction of the time, but soon he awoke to the realization that in the "prose tale" he had a literary form that could express all that his imagination might body forth. From the time of his assumption of the editorship of the *Southern Literary Messenger*, until near the time of his death, he was by profession a magazine editor, and more and more his product was stamped with magazine requirements. "The whole tendency of the age," he wrote in 1840, "is magazineward." And the magazine demanded originality, variety, piquancy, movement. "We now demand," he wrote, "the light artillery of the intellect; we need the curt, the condensed, the pointed, the readily diffused—in place of the verbose, the detached, the voluminous, the inaccessible." And Poe gave in his tales what the age demanded: originality, sensation, shortness, variety. His total product is remarkably varied. It hardly seems as if "The Fall of the House of Usher" could have come from the same pen as "The Murders in the Rue Morgue" which is the parent of the modern detective story. He was of the school of Coleridge in all his work: unlike Hawthorne, he stood for art for mere entertainment, art without moral basis or message, "art for art's sake."

During the decade after Poe's death in 1849, the decade of the Bohemian group of writers in New York, the short story languished. With the entry of a veritable swarm of "female writers" into the field of fiction the "tale" became a sentimental thing, delighting in the romantic and the marvellous, and the mawkishly pathetic. The influence of Dickens was everywhere apparent. It was the decade of Fitz-James O'Brien, the brilliant leader of the Bohemians and the creator of a few remarkable tales like "The Diamond Lens" and "What was It?" But O'Brien was too headlong, too impatient, too intense. He finished nothing.

Just before the Civil War a revivifying breath came to American fiction through the new *Atlantic Monthly* (1857) under the editorship of James Russell Lowell. Lowell himself wrote no fiction but he had positive convictions as to the nature and demands of this literary form. He believed in the short story as a dignified piece of art; during his editorship of the magazine there was an average of three stories in every number. And he demanded actuality,—he preferred tales of humble life with characters from the Hosea Biglow area of society. As a result his leading contributor was Rose Terry Cooke, who put into short fiction (eight stories in the first year of the magazine) the first actually realistic studies of New England rural life. Other contributors were Rebecca Harding, whose "Life in the Iron Mills" was as grim a piece of realism as may be found in American literature, and Edward Everett Hale, who added a whimsical lightness of touch to his tales that gave them a distinction of their own. His tale, *The Man Without a Country*, has become an American classic.

POST CIVIL WAR PERIOD

The Civil War was followed by an expansion period. Railroads were pushed in all directions and by the end of the decade of the '60s the first line had been completed across the continent into California. The telegraph had annihilated distance, and provincialism was everywhere breaking down. The result was a new discovery of America—by Americans themselves. Bret Harte was the pioneer in the new period. From the California which had become to the world almost a fabulous area, came in 1868 a new and startling type of short story, highly picturesque, wrought with dramatic art, furnished with characters after the Dickens model, and though really romantic, so told as to suggest the barest realism. The "Luck of Roaring Camp" stories mark the beginning of a new period in the history of the short story. The fame of such exquisite pieces of art as "Tennessee's Partner" and "The Outcasts of Poker Flat" swept over America and then over England like a prairie fire. They advertised the short-story form enormously. Soon "local colour" tales were coming in from every picturesque area in America. Mark Twain came in from Nevada and the Comstock Lode with "The Jumping Frog" extravaganza, from New Orleans George W. Cable sent his "Old Creole Days" tales, from the Lake country Constance Fenimore Woolson contributed her "Castle Nowhere" tales. Then from New England came Sarah Orne Jewett's and later Mary Wilkins Freeman's stories, from Tennessee Mary N. Murfree's studies of the Great Smoky mountains signed with the pen name "Charles Egbert Craddock," from Georgia came the inimitable Uncle Remus folk-lore stories by Joel Chandler Harris. "Local colour" swept into the magazines in a veritable flood. The high tide came in the mid '80s, when Thomas Nelson Page's "Marse Chan," written wholly in negro dialect, appeared in the *Century Magazine*.

Henry James.—Not all of the short stories of the period were in "local colour." Henry James was evolving his psychological studies into a short story form of his own devising—the story of character analysis developed scientifically by the aid of a multitude of minute touches. He needed room for this variety of tale, always two and three magazine numbers, yet it is impossible to classify these pieces other than as short stories. As compared with the novel he considered the short story form inferior, yet he never abandoned it, and first and last he expressed in it some of his strongest contributions. His gruesome tale "The Turn of the Screw" is a masterpiece.

Lightness and humour and finesse were brought to the short story by Frank Stockton, whose extravaganzas, like "The Transferred Ghost" and "Negative Gravity," done with verisimilitude—outrageous impossibilities rendered seemingly possible and even

probable—are unique. His story *The Lady or the Tiger?* with its ingenious ending, became, perhaps, the most famous story of its period. Its influence was surprising and far-reaching. It impelled Brander Matthews to write his suggestive article *The Philosophy of the Short-Story,* in which he suggested that since the French term *conte* was not available for the new form the term Short-Story should be written with a capital and hyphenated to distinguish it from the story that was merely short. It also awakened Henry Cuyler Bunner, editor of *Puck,* who wrote his *Short Sixes* series of tales with a mastery of art that showed the larger possibilities of the short-story form.

Then with the '90s came the era of the handbooks, a veritable outpouring of text-books formulating short-story art, collections of specimens, and outlines for correspondence courses. A study of the art of short-story writing was soon introduced everywhere into the courses of high schools and colleges. Then had come the O'Brien annual with specimens of the best product of the year, to be followed by the O. Henry Society annual. With the '90s came also an increasing output of stories of every variety. Magazines were cheapened and multiplied and their prosperity rendered them able to pay high prices for short-story contributions. The decade saw the beginnings of the short-story work of Hamlin Garland, whose *Main Travelled Roads* volume is distinctive, the first works of James Lane Allen, Richard Harding Davis, Mary E. Wilkins Freeman, Alice Brown, Ambrose Bierce and a host of others.

Jack London.—With the opening of the new century came two creators who were able to deflect the current of the short story into new channels, Jack London and Sydney Porter. London, a native of California, an adventurer, a sailor with the sealing fleet, a tramp, a miner in Alaska in the first days of the gold rush, an explorer in his own yacht of the South Seas, gave first of all Alaska tales, *The Call of the Wild,* episodes in the life of a super-dog of the North, and when that gold lode was exhausted, wild adventure tales of the cannibal seas. He wrote with colour, exaggeration, poetic abandon, with movement always and romantic atmosphere, and he gave always the sense of actuality, the impression that he himself had been present and that this was a part of his own life.

O. Henry.—Sydney Porter, who wrote under the pen-name "O. Henry," was also an adventurer,—a ranchman in Texas, a fugitive in South America, an inmate of the Ohio State prison, a reporter on a New York newspaper. He was a humorist, an entertainer, a man with a bag of literary tricks which he handled most dexterously, and withal he was gifted with a style which at times is exquisite, and with a vocabulary that is worth one's study. His tales are padded with slang, with surprises within surprises, with outrageous comparisons, and antitheses—everywhere the unexpected. Enormous was their popularity. Sets of his books were sold by the hundreds of thousands. His influence was such that for a time it swung the short story almost wholly to manner rather than to matter.

The waning of the O. Henry influence was followed by a reign of short-story lawlessness—deliberate revolt. The younger group which in 1929 was in the fullness of its creative powers, seems to be striving for originality, for strangeness, for a breaking away from the conventions so long in force. With the new century had come realism and disillusion in increasing power until they have become a ruling force. We can only say that short-story making and teaching have become veritable national industries and the output seems to be increasing. (F. L. Pa.)

SHOSHONE. This loose group of western American Indian bands gave name to the much larger Shoshonean family, or Shoshonean branch of the Uto-Aztecan family. The Shoshone proper occupied a continuous territory from central Wyoming to eastern California, and an offshoot, only dialectically different, are the Comanche of Texas. The culture varied, according to locality, from Great Basin (Plateau) to Plains type. Politically, the Shoshone have always been disunited.

SHOSHONG, a town in the British protectorate of Bechuanaland, formerly the chief settlement of the eastern Bamangwato. It is about 200 m. N.N.E. of Mafeking and 30 m. N. of Shoshong Road station on the Cape Town-Bulawayo railway. At the time of the declaration of a British protectorate in 1885 Shoshong had 20,000 to 30,000 inhabitants, including about twenty Europeans. Being the meeting place of trade routes from south and north it was of considerable importance to early explorers and traders in South-Central Africa. The population is now about 800. (*See* BECHUANALAND.)

SHOT TOWER, a tower generally about 200 feet high in which gun shot is made by dropping melted lead through a sieve, or drop pan, at the top to a tank of water at the bottom, the falling liquid assuming the round form of raindrops. The largest shot made this way, .20 inches in diameter, is dropped through about 150 feet; the smallest, dust shot, through 40 feet. The shot is polished by rotating it in a barrel with graphite. There are several shot towers in operation in England; in the United States there are shot towers at New Haven and Bridgeport, Connecticut; East Alton, Illinois; Kings Mills, Ohio; and San Francisco.

SHOTTS, mining and manufacturing parish of Lanarkshire, Scotland. It comprises eight villages, parts of two others, and the town of Cleland and is served by the L.N.E. and L.M.S. railways. Pop. (1931) 20,537. The parish contains large ironworks, collieries and quarries. Matthew Baillie (1761–1823), and Janet Hamilton (1795–1873), the poetess, were born in the parish of Shotts.

SHOVEL, SIR CLOUDESLEY or CLOWDISLEY SHOVELL as he seems to have spelt the name himself (*c.* 1650–1707), English admiral, was baptised at Cockthorpe in Norfolk on Nov. 25, 1650, and went to sea under the care of his kinsman Sir Christopher Mynns. He was present as captain of the "Edgar" (70) at the first fight at Bantry Bay, and shortly afterwards was knighted. In 1690 he convoyed William III. across St. George's Channel to Ireland; the same year he was made rear-admiral of the blue, and was present at the battle of Beachy Head on July 10. In 1692 he was appointed rear-admiral of the red, and joined Admiral Russell, under whom he greatly distinguished himself at La Hogue, by being the first to break through the enemy's line. When Russell was superseded, Shovel was put in joint command of the fleet with Admiral Killigrew and Sir Ralph Delaval. In 1702 he brought home the spoils of the French and Spanish fleets from Vigo, after their capture by Sir George Rooke, and in 1704 he served under Rooke in the Mediterranean and co-operated in the taking of Gibraltar. As commander-in-chief of the British fleets he co-operated with Peterborough in the capture of Barcelona in 1705, and commanded the naval part of the unsuccessful attempt on Toulon in October 1707. When returning with the fleet to England his ship, the "Association," struck on the rocks near Scilly (Oct. 22), and was seen by those on board the "St. George" to go down in three or four minutes' time, not a soul being saved of 800 men that were on board. The body of Sir Cloudesley Shovel was cast ashore next day, and was buried in Westminster Abbey.

See *Life and Glorious Actions of Sir Cloudesley Shovel* (1707); Burnet's *Own Times;* various discussions in *Notes and Queries,* 5th series, vols. x. and xi.; and T. H. Cooke, *Shipwreck of Sir Cloudesley Shovel* (1883).

SHOVELLER, a word originally applied to the bird now termed spoonbill (*q.v.*), but now used of *Spatula clypeata,* a duck characterized by its broad flat beak, the edges of which are beset with long lamellae by means of which food particles are filtered off from the water just as is done by the baleen in whalebone whales. The shoveller is a surface-feeding duck, and the male, with his contrasted plumage of white, brown and bay, dark green head and speculum, and orange feet, is a handsome bird. The female resembles in plumage the ordinary wild duck. The shoveller breeds locally over the greater part of Europe (including Great Britain), Asia and North America, wintering farther south, where it reaches India, Abyssinia, Central America and even Australia. Other species inhabit South America, South Africa, Australia, and New Zealand.

SHRAPNEL: *see* AMMUNITION.

SHREVEPORT, a city of north-western Louisiana, U.S.A., at the head of navigation on the Red river; the capital of Caddo parish. It has a municipal airport; is on Federal highways 71, 171 and 80; and is served by the Illinois Central, the Kansas

City Southern, the Louisiana and Arkansas, the Louisiana Railway and Navigation company, the St. Louis South-western, the Southern Pacific and the Texas and Pacific railways, and by numerous motor-bus and motor-truck lines. Pop. 43,874 in 1920 (57% native white and 40% negroes); 67,641 in 1927, according to a special enumeration under the supervision of the Federal Census Bureau; and, after annexations of territory, was 76,655 in 1930 by Federal census.

The city has an area of 27 sq.m., an assessed valuation for 1927 of $121,111,580, and a commission form of government. The Caddo parish court-house (completed in 1928, at a cost of $1,250,000) is a structure of unusual beauty and many interesting features, including a gaol on the seventh and eighth floors, the highest in the building. The city has 56 schools, 98 churches representing 12 denominations, nine hospitals with a total of 1,000 beds, 22 hotels with a total of 1,500 guest-rooms, a municipal auditorium seating 5,000, and seven theatres, including a charming playhouse for the "little theatre." It is the seat of Centenary college (Methodist; founded at Jackson in 1825 and moved to Shreveport in 1908) and the Dodd Junior college (1927), and the home of the Louisiana State fair. There are 12 lakes in the vicinity, providing good fishing and duck-hunting. Shreveport is the largest city within a radius of 175 m., and therefore an important commercial and financial centre. Its trade territory covers a rich agricultural region, vast forests of hard and soft woods, and one of the greatest oil and gas areas of the Mid-Continent field. The Caddo oil-field, north-west of the city, which field includes the Caddo Lake in its area, produced 4,067,000 bbl. in 1925. The city is headquarters for 230 oil-operating firms or individuals, and has seven large refineries. Petroleum products constitute about half (measured by value) of its total factory output, which in 1927 was valued at $20,707,409 and included 90 different products. Lumber and lumber products, on which the earlier development of the city was based, rank second in importance, and fertilizer to the amount of 75,000 tons is manufactured annually. Bank debits for 1926 aggregated $483,902,000.

Shreveport is in the Caddo Grant, a tract ceded to the United States by the Caddo Indians in 1837. In 1835 Captain Henry Miller Shreve (who had charge of improvements on the western rivers from 1826 to 1841) came up the river in his snag boat and founded a settlement here. In 1839 Shreve's Landing was incorporated as a town, and the city was chartered in 1871. In 1862, after the capture of Baton Rouge and New Orleans by the Unionists, Shreveport was occupied by the Confederate officials of the State. In the spring of 1864 it was the objective of combined land and naval expeditions of Union forces, in the course of which the Federals were worsted at Mansfield on April 8, and the Confederates at Pleasant Hill on April 9. Development of the oil and gas resources of the region began in 1906.

SHREW, a term applied to the members of the family *Soricidae* of the mammalian order Insectivora (*q.v.*).

Sorex araneus, the common shrew, or shrew-mouse (though it does not resemble the mouse in structure or in habits) is a small animal about the size of a mouse, but distinguished externally by its long slender muzzle, which projects far beyond the lower lip. The small eyes are almost concealed by fur; the ears are short, wide and provided internally with a pair of deep folds capable of closing the entrance; the tail is slightly shorter than the body, quadrangular in section, and hairy, with a short tuft at the tip. The body fur is soft and dense, brown above, grey below. Between the elbow and the knee is a gland secreting a fluid with an unpleasant cheesy odour.

The lesser or pigmy shrew (*S. minutus*) is smaller and differs slightly in its dentition. Like the last, it extends across the whole of Europe and Asia. Both live in the neighbourhood of woods, feeding by night on insects, worms, and slugs. They are pugnacious and very voracious and produce five to seven naked, blind, and toothless young in a litter.

The alpine shrew (*S. alpinus*) is restricted to the Alps of Central Europe. It is slightly larger than the common shrew and the fur is uniformly dark.

The largest American shrew is *S. bendiri.* Numerous other species, many belonging to the allied genus *Blarina,* characterized by a short tail, occur on this continent. They resemble the Old World shrews in habits.

The water-shrew (*Neomys fodiens*) is larger than the common shrew and aquatic in habits. It has much the same range as *S. araneus.* In America, two species of *Sorex* are aquatic, *S. palustris* being the commonest.

SHREWSBURY (shrōz'brĭ), **EARLS OF.** This, one of the most ancient Earldoms in the English peerage, dates from the time of William the Conqueror. Roger de Montgomery (*c.* 1030–1094), son of another Roger de Montgomery, known as "the Great," was a councillor of William, duke of Normandy, before his invasion of England, and was probably entrusted by William with the government of Normandy during the expedition of 1066. Roger received territory in Sussex, including the city of Chichester and the castle of Arundel, he became earl of Arundel, or probably and more correctly earl of Sussex. In 1071 the greater part of the country of Shropshire was granted to him, carrying with it the title of earl of Shropshire, though, from his principal residence at the castle of Shrewsbury, he like his successors was generally styled earl of Shrewsbury. He probably exercised palatine authority. He was the founder of Shrewsbury Abbey in 1083. His first wife was Mabel, daughter of the seigneur of Belesme and Alençon; hence his son Robert, who, after the death of another son, Hugh, succeeded to the earldoms of Shrewsbury and Arundel, was generally known as Robert de Belesme (*q.v.*), one of the most celebrated of the feudal nobles in the time of Henry I. Robert having been deprived of all his English estates and honours in 1102, the earldom of Shrewsbury was next conferred in 1442 on John, 5th baron Talbot, whose descendants have borne the title to the present day. (*See* TALBOT; and SHREWSBURY, 1ST EARL OF.)

SHREWSBURY, CHARLES TALBOT, DUKE OF (1660–1718), only son by his second wife of Francis Talbot, 11th earl of Shrewsbury, was born on July 24, 1660. His mother was a daughter of Robert Brudenell, 2nd earl of Cardigan, and the notorious mistress of the 2nd duke of Buckingham, by whom his father was killed in a duel in 1668. Charles was a godson of Charles II., and he was brought up as a Roman Catholic, but in 1679 under the influence of Tillotson he became a member of the Church of England. On his father's death in 1668 he succeeded to the earldom of Shrewsbury; he received an appointment in the household of Charles II., and served in the army under James II. But in 1687 he was in correspondence with the Prince of Orange, and he was one of the seven signatories of the letter of invitation to William in the following year. He crossed to Holland to join William, and landed with him in England in November 1688. Shrewsbury became a secretary of state in the first administration of William and Mary, but he resigned office in 1690 when the Tories gained the upper hand in parliament. While in opposition he brought forward the triennial bill, to which the king refused assent. In 1694 he again became secretary of state; but there is some evidence that as early as 1690, when he resigned, he had gone over to the Jacobites and was in correspondence with James at St. Germains. It has been stated that William connived at the correspondence. However this may be, William seems not to have suspected Shrewsbury's loyalty, for he was created marquess of Alton and duke of Shrewsbury, and acted as one of the regents during the king's absence from England. In 1696 definite accusations of treason were brought against him by Sir John Fenwick, which William himself communicated to Shrewsbury. The latter asked to resign on ground of health, and in 1700 the king accepted his resignation reluctantly.

For the next seven years Shrewsbury lived abroad, chiefly at Rome, whence in 1701 he wrote a letter to Lord Somers declaring that if he had a son he "would sooner bind him to a cobbler than a courtier, and a hangman than a statesman." When he returned to England in 1707 he gradually became alienated from his old Whig associates, and in 1710 became lord chamberlain in the Tory administration, to which the queen appointed him without the knowledge of Godolphin and Marlborough, while his wife

was at the same time made a lady of the bedchamber. Shrewsbury became lord lieutenant of Ireland in 1713; but he was in London in July 1714 during the crisis occasioned by the impending death of Queen Anne. On July 27, when the queen was dying, Oxford was dismissed, and Anne appointed Shrewsbury to the vacant treasurership. When the queen died on Aug. 1, Shrewsbury was able to influence the succession to the crown. He threw his influence into the scale in favour of the elector of Hanover, and powerfully promoted the peaceful accession of George I. He exchanged his onerous office for that of lord chamberlain. This also he resigned in 1715. He died on Feb. 1, 1718.

In 1705 Shrewsbury married Adelaide, daughter of the Marquis Paleotti of Bologna. On the accession of George I. the duchess became a lady of the bedchamber to the princess of Wales. Shrewsbury left no children, and at his death the dukedom became extinct, the earldom of Shrewsbury passing to his cousin Gilbert Talbot. (*See* TALBOT.)

See *Correspondence of Charles Talbot, Duke of Shrewsbury, with King William, the Leaders of the Whig Party, &c.*, edited by W. Coxe (London, 1821); Gilbert Burnet, *History of his own Time* (6 vols., 2nd ed., Oxford, 1833); F. W. Wyon, *History of Great Britain during the Reign of Anne* (2 vols., London, 1876); Earl Stanhope, *History of England comprising the Reign of Anne until the Peace of Utrecht* (London, 1870), and *History of England from the Peace of Utrecht*, vol. i. (7 vols., London, 1836–54); *The Wentworth Papers*, edited by J. J. Cartwright (London, 1883); W. E. H. Lecky, *History of England in the Eighteenth Century*, vol. i. (new edition, 7 vols., London, 1892); and G. E. C., *Complete Peerage*, vol. vii. (London, 1896).

SHREWSBURY, ELIZABETH TALBOT, COUNTESS OF (1518–1608), better known as "Bess of Hardwicke," was the daughter and co-heiress of John Hardwicke of Hardwicke, Derbyshire. She was four times married—to John Barlow, Sir William Cavendish, Sir William St. Lo (or St. Loe), and finally, in 1568, to George Talbot, 6th earl of Shrewsbury. With each marriage she made a good settlement, and before she married Shrewsbury was accounted the wealthiest woman in England. She now arranged a marriage between her daughter Elizabeth and Charles Stuart, brother of Lord Darnley, without consulting her husband. Since the Lennox family were of royal blood, Elizabeth thought the countess over-ambitious, and sent her to the Tower for a short time. The child of the Stuart marriage was the unfortunate Arabella, a claimant to the throne.

By this time the earl of Shrewsbury and his wife were on very bad terms with one another, and the former tried to obtain a divorce. The countess revenged herself by accusing him of a love intrigue with the queen of Scots, a charge which she was forced to retract before the council. In the meantime she repeated scandal about Elizabeth to Queen Mary, who made use of it in the extraordinary letter she wrote some time in 1584. In 1583 the countess of Shrewsbury went to live apart from her husband, with whom she was afterwards reconciled formally by the queen. After his death, in 1590, she lived mostly at Hardwicke, where she built the noble mansion which still stands. She was, indeed, one of the greatest builders of her time at Hardwicke, Chatsworth and Oldcoates. It is said that she believed she would not die so long as she was building. Her death came on Feb. 13, 1608, during a frost which put a stop to her building operations. She was buried in All Saints' church, Derby, under a fine monument with a laudatory inscription which she took care to put up in her lifetime.

See White Kennett, *Memoirs of the Cavendish Family* (London, 1708); and Mrs. Murray Smith (Miss E. T. Bradley), *Life of Arabella Stuart* (London, 1889); Mrs. Stepney Rawson, *Bess of Hardwicke* (1910).

SHREWSBURY, JOHN TALBOT, 1ST EARL OF (d. 1453), was second son of Richard, 5th baron Talbot, by Ankaret, heiress of the last Lord Strange of Blackmere. He was married before 1404 to Maud Neville, heiress of the barons Furnivall, and in her right summoned to parliament from 1409. In 1421 by the death of his niece he acquired the baronies of Talbot and Strange. He served in the Welsh wars (1404–13), was lord lieutenant (1414–19) of Ireland, where he saw more fighting, had a command in France (1420–24), and, after a brief stay at home on the Welsh marches, he was back at the French war in 1427. He fought at the siege of Orleans. Talbot's stubborn rashness was chiefly to blame for the English defeat at Patay in June 1429. After Patay Talbot was four years a prisoner. On his release he became one of the foremost of the English captains. In 1434 he recovered the county of Clermont, next year took part in the siege of St. Denys, and in 1436 by reducing and harrying the revolted Pays de Caux saved Normandy. He was rewarded with the offices of captain of Rouen and marshal of France. During five years as a dashing fighter he was the mainstay of the English cause. His chief exploits were the defeat of the Burgundians before Crotoy in 1437 and the recovery of Harfleur in 1440. In 1442 during a visit to England he was created earl of Shrewsbury. In November he was back in France besieging Dieppe; but "fared so foul with his men that they would no longer abide with him" and was forced to break the siege (*Chronicles of London*, p. 150). In March 1445 he was once more sent to Ireland, where he used his old methods, so that the Irish said "there came not from the time of Herod any one so wicked in evil deeds." In 1449 he served for a short time in Normandy.

When in 1452 the Gascons appealed for English help, Shrewsbury was the natural leader of the expedition. He landed in Aquitaine on Oct. 17. Bordeaux and the surrounding district returned quickly to their old allegiance, and in the following summer Shrewsbury captured Fronsac. In July the French besieged Castillon. Shrewsbury hurried to its relief, and with foolhardy valour attacked the enemy in their entrenched camp without waiting for his artillery. The English and Gascon footmen charged in vain in face of the French cannon, until Shrewsbury and the flower of his troops had fallen. This happened in July 1453, and was the end of the English rule in Gascony. Shrewsbury's fighting qualities made him something of a popular hero, and in the doggerel of the day he was "Talbot our good dog," whose valour was brought to nought by the treason of Suffolk. But in truth though a brave soldier he was no general. He was twice married, his second wife being Margaret, eldest daughter of Richard Beauchamp, earl of Warwick.

BIBLIOGRAPHY.—For Shrewsbury's French campaigns see especially the *Chronique* of E. de Monstrelet, Jehan de Waurin and Matthieu d'Escouchy (all these are published by the *Société de l'Histoire de France*), and the *Chronicles of London* (ed. C. L. Kingsford, London, 1905). Also H. Ribadieu, *Conquête de Guyenne* (1866); J. T. Gilbert, *Viceroys of Ireland* (1865); and J. H. Wylie's *Henry the Fourth* (1884–1898) for his early career.

SHREWSBURY (Salop; Welsh Amwythig), an ancient market centre and the county town of Shropshire, England. Pop. (1931) 32,370. Its position in relation to the routes leading into Wales and along the border has made it a town of great importance. The old part of the town, including churches, old houses and market hall, lies almost entirely within the remarkable southward loop here described by the Severn.

History.—The picturesque red-sandstone castle, built originally by Roger de Montgomery (1070), crowns the narrow bluff which forms the neck of the peninsula. Under the castle clusters the town, with its half-timbered houses and narrow, quaintly-named streets, leaving the public park or Quarry, outside the old walls but still within the loop of the river. Over its two ancient bridges, the English and the Welsh, the town early spread east and west into Abbey Foregate, around the abbey church and into Frankwell on the Welsh side. The strategic position of the peninsula rising above the Severn floodlands was recognized from the time of the princes of Powys, who made it their seat, called Pengwern, in the 5th and 6th centuries. At the end of the 8th century it was engulfed in the province of Mercia and given its Saxon name Scrobesbyrig, with alternative Sloppesbury, from which came the modern titles, Shrewsbury and Salop, respectively.

As a Saxon and Norman town it became the base of operations, alike of war and peace, extending up the lowland ways westward into the upper Severn valley. Being one of the chief border towns it was besieged and plundered by the Welsh on numerous occasions, and was never without fear of sudden raids. The first extant charter, dated 1199, is a grant by Richard I. to the burgesses of the town at a fee farm of 40 marks, but Henry II. is known

to have granted an earlier charter which was confirmed by King John in 1200. Henry II. in 1227 granted a gild merchant with a house. Besides these charters there are numerous confirmations before the incorporation charter of Elizabeth of 1586. Charles I. in 1638 altered the corporation to a mayor, 24 aldermen and 48 assistants. In 1684 the burgesses surrendered their charter to the king and received a new one in the following year which, however, did not change the form of government. In 1403, at Battlefield on the north side of the town, Henry Percy was defeated by Henry IV. During the late Middle Ages and again in Tudor and Elizabethan times the town profited greatly from trade with the Welsh in wool and flax. The Severn was navigable for about 40 m. above Shrewsbury, and this enabled a vast amount of commerce to be carried on with Gloucester and Bristol.

With the establishment of law and order in the Marches in Tudor times, Shrewsbury and the border saw a period of great prosperity which had as one of its expressions the spread of the custom of building half-timbered houses. Ireland's mansion (*c.* 1580), Owen's mansion (*c.* 1592), the Drapers' hall and the stone Market hall are examples of the art which culminated at this time. Another feature of border or "fall line" towns in general is exemplified by growth of the industry of printing, *e.g.*, of many Welsh books in the 17th century. The importance of the town houses of the country gentry in the 18th century consolidated the position of the town as a regional centre; while as a market and route town it has continued to flourish. The remarkable concentration of road and rail routes can be best seen from a map. Since 1918 important steam-waggon works and other industries have grown on flat lands to the north of the old settlement; and additions to the town are extending along all the main roads so that the effective urban population is much larger than the census figure given, being probably 35,000 or 40,000. Old established industries include brewing, melting and tanning. The general station, a joint station of the G.W.R. and L.M.S.R., deals with a vast amount of traffic, and the labour attracted is one important feature of the town's development.

Buildings, etc.—Shrewsbury castle, now the property of the mayor and corporation, was restored by Telford, but retains the walls of the inner court and two round Edwardian towers. Opposite the castle entrance are the old grammar school buildings, in front of which is a bronze statue of Darwin, who was born at the Mount, in Frankwell. The schools now occupy a site south of the river, in Kingsland, formerly the scene of the Shrewsbury show, a pageant held during the Festival of Trinity. St. Mary's church, in a commanding position on high ground south of the castle, is a noble building with a lofty tower and spire, displaying examples of various styles of architecture from early Norman to Perpendicular. It has some interesting painted glass brought from the abbey of Altenburg and a large 14th century Jesse window at the east end, taken from Old St. Chad's. St. Alkmond's and St. Giles's are old foundations, much altered subsequently. Old St. Chad's church was destroyed by the fall of the tower in 1788, the new church being built shortly afterwards, on a new site, with a round auditorium. The restored Abbey church (Holy Cross), retains its massive Norman nave, built of deep red sandstone, and there also remain two Early English arches and an imposing decorated western tower. Of the monastic buildings little is left, save a remarkable roofed outdoor pulpit of ornate Decorated work.

In the centre of the old town is the Market square with the old market house, an Elizabethan building of 1596. Butcher row, up a narrow "shut" from the square, contains some noteworthy 15th century houses.

Shrewsbury is the seat of a Roman Catholic bishop. For purposes of parliamentary representation the borough is included in the Shrewsbury division, together with the rural districts of Atcham and Chirbury.

SHRIKE or **BUTCHER-BIRD,** the common names of birds of the family *Laniidae. Lanius excubitor,* the greater butcher-bird, or great grey shrike—a bird which visits the British Islands in autumn or winter and occasionally in the summer; breeds from the north of France to within the Arctic Circle. Exceeding a song-thrush in length, it is more slender; pearly grey above with a black band on the head, beneath it is nearly white, or in Eastern varieties with dusky bars. The wings and tail are black and white. The smaller red-backed shrike, *L. collurio* is a well-known summer visitor to Great Britain. The cock has a grey head and neck, black cheek-band, chestnut back and pale rosy breast, while the hen is duller. The nest, in a clump of brambles, thicket or hedge, contains five or six eggs, very variable in colour but usually spotted with brown or red-brown. The alarm note is harsh. The woodchat, *L. senator,* is a third European species. All these birds have the remarkable habit of catching insects, frogs, lizards or small birds and mammals, and of spitting them on thorns in a "larder" near their nest, to eat them later.

The *Laniidae* occur both in the Old and New World. The shrikes are active and powerful birds, with stout bills often strongly hooked. Their diet is chiefly insects and small frogs, lizards, birds and mammals, but they also take seeds and fruits.

SHRIMP, a name applied in general to the smaller Crustacea of the sub-order *Natantia* of the order *Decapoda.* The shrimps and their allies are distinguished from the larger macrurous Decapoda such as the lobsters and crayfishes, by greater development of the paddle-like limbs of the abdomen or tail, which are used in swimming. The abdomen is usually sharply bent between the third and fourth segments and has a characteristically humped appearance when straightened out.

The common shrimp (*Crangon vulgaris*) of northern Europe is found abundantly in shallow water wherever the bottom is sandy. It is 2 or 3in. long, slightly flattened, and with the rostrum or beak, in front of the carapace, very short. It is of a translucent greyisn colour, speckled with brown and closely resembles the sand in which it lives. On many parts of the coast the shrimp fishery is of considerable importance.

The larger shrimp-like Crustacea are generally known as "prawns," the name being especially applied in Britain to *Leander serratus,* which is highly esteemed for the table. In warmer seas many other kinds of prawns are caught for food. These are generally species of *Penaeus,* which are distinguished from all those already mentioned by having pincers on the first three, instead of only on the first two, pairs of legs. The large river-prawns of the genus *Palaemon* (closely allied to *Leander*) found in most tropical countries are also often used as food. In the West Indies *Palaemon jamaicensis,* and in the East Indies *Pal. carcinus,* attain almost the dimensions of full-grown lobsters. (W. T. C.)

The annual catch of shrimps in the United States is about 70,000,000 lb. Most of this is taken along the southern coast from North Carolina to Texas. Louisiana, Florida, Georgia and Mississippi lead in the order named. The shrimp canners in this region pack about 14,000,000 lb. annually. The shrimps are put up in two forms, the "dry" pack and the "wet" pack.

In Japan, the annual catch ranges between 35,000,000 and 50,000,000 lb. The fishery is carried on chiefly in the southern half of the empire, in the inland sea and bays. Hand trawls and Japanese trawls are used. The Gulf of California, Mexico, has at times been the centre of a considerable shrimp fishery, particularly along the coasts of Sinaloa.

SHROPSHIRE (Salop), a county of England on the Welsh border, bounded north by Cheshire and a detached portion of Flint, east by Staffordshire, south-east by Worcestershire, south by Herefordshire, south-west by Radnorshire, west by Montgomeryshire and north-west by Denbighshire. The name Salop, in common use, comes from an early name of the county town of Shrewsbury (*q.v.*).

Towards the west Shropshire is hilly, while nearly all the county south of the Severn is upland. This comprises the Long Mountain and a small part of the conspicuous Breidden group in the west, the Shelve hill lines, Longmynd (1,696 ft.), the Caradoc range, and Wenlock Edge (1,000 ft. to 1,200 ft.), with Clun Forest in the south-west, the Clee hills in the south-east, and the Wrekin (1,335 ft.). The Wrekin is an isolated hill north of the Severn. The pre-Cambrian series of rocks are represented here and in the adjoining Ercall hill (granitoid and gneissic rocks) and again in the line of "hog-backs" including Lawley and Caradoc

running south-west. These consist of volcanic lavas and tuffs, and are, with the Wrekin, among the oldest hills in the British Isles. Next in point of age come the conglomerates, grits and shales of the Longmynd. The mass of these well consolidated rocks makes a flat-topped plateau of 4 or 5 sq.m., which faces the Caradoc hills across the Church Stretton valley. Cambrian rocks succeed hard quartzites and sandstones, with soft shales (Shineton Shale) which have been eaten out to form the hollow west of Longmynd. The Ordovician system is represented by the resistant quartzites of the Stiperstones, the volcanic ashes of Shelve Hill, the grits of Snailbeach, the sandstones of Hoaredge and a few intrusions of volcanic rocks.

Silurian rocks outcrop in the shape of a horseshoe around the mountain mass from Stiperstones to Caer Caradoc, being represented by mudstones in the smoothly contoured Long Mountain, whose slopes, nevertheless, have deep hidden dingles, by sandstones and shales in the Clun Forest and by the mudstones of Wenlock and Ludlow, with the interstratified limestones of Wenlock and Aymestry which form an unbroken scarp for 17 m. in the remarkable Wenlock Edge. This is in reality a double ridge made of two "edges," the higher and eastern of which is sometimes called View Edge. The steep scarps of both "edges" look to the north-west, and are densely clothed with woods of beech, oak, elm and hazel, while the gentler "dip-slopes" are arable and pasture.

Old Red Sandstone outcrops in the Clee hills (Titterstone Clee 1,749 ft. and Brown Clee 1,792 ft.) which stand so high because they are covered by layers of the next division of rocks, the Carboniferous, here protected in turn by a capping of hard igneous intrusive dolerite known locally as "Dhu-Stone." The Old Red Sandstone group also has extensive out-liers at Clun and Bettws-y-Crwyn among the Silurian rocks of the south-west of the county.

The Carboniferous Limestone and Millstone Grit of the Denbighshire coalfield enter the county near Oswestry in the north-west lobe, and end in the conspicuous cliff of Llanymynech hill, overlooking the Vyrnwy and Severn flats. They also appear at Lilleshall and Coalbrookdale on the west border of the eastern coalfield, and include the little coalfield of Titterstone Clee.

Elsewhere in the Hanwood, Coalbrookdale and Forest of Wyre coalfields these lower rocks are absent, and the Coal-Measures rest directly on Silurian, Ordovician and Cambrian rocks. The Coal-Measures, with their coal seams and bands of ironstone, are of great economic importance. Triassic deposits, laid down in a lake whose south shore was not far from the present border of "the Upland," cover most of north Shropshire. An island of Longmyndian rock (Haughmond Hill) and a peninsula of coal-measures (from Coalbrookdale to Lilleshall) outcrop from these sandstones, marls and conglomerates. Around Wem and Prees is a capping of Liassic clays, while outcropping conglomerates or breccias form the hills of Nesscliff, Pim Hill, Grinshill and Hawkstone. Over much of the plain, glacial deposits—boulder-clay, gravel and sand—are spread. Some peat bogs in the drift-covered region towards the Cheshire border appear to occupy the sites of lakes, of the type of the meres of the Ellesmere district, in the irregular morainic material.

The north and east of the county lie almost entirely in the basin of the Severn, which enters from Montgomeryshire and flows eastward to Shrewsbury, after which it turns south-eastward to Ironbridge, and then continues in a more southerly direction past Bridgnorth, entering Worcester near Bewdley. The scenery is striking at some places, as near the finely situated town of Bridgnorth, but it is spoilt near Coalbrookdale by factories. Its principal tributaries within Shropshire are: the Rea, Cound, Borle, Vyrnwy (a well-known trout-stream forming part of the boundary with Montgomeryshire), Perry, Tern, which receives the Roden, and the Worf. The Dee and its tributary the Ceiriog touch the north-western boundary of the county with Denbighshire.

In the south the Teme, which receives the Clun, the Onny and the Corve, flows near the Herefordshire border, which it intersects. Salmon are taken in the Severn and trout and grayling from the Teme. There are small lakes near the Denbighshire border, of which the largest is Ellesmere.

Early History.—Evidence of prehistoric occupation comes chiefly from the open hills of the south. A few stone circles and menhirs occur, like the Bronze Age tumuli, chiefly on the Longmynd, Clun Forest and other parts of the Upland. Shropshire is rich in earth encampments, possibly Early Iron Age, in some cases used if not made in Romano-British and even Saxon times. Examples crown the Wrekin, Gaer Caradoc and the two Clees. In the north are Bury Walls (on Hawkstone) and Old Oswestry (*see* OSWESTRY) with its six-fold embankment, but in prehistoric times swamp marsh and woodland must have seriously affected any attempt at permanent settlement. The "islands" of Haughmond and Grinshill may have been used as stepping-stones in a trade route of the early metal age which followed the watershed between the Perry and the Tern.

The Romans built a city, Viroconium or Uriconium (*q.v.*) (modern Wroxeter) at the junction of roads from north, south, west and east (Watling Street). It is situated some five m. below Shrewsbury, whose functions as a route centre and border town it so remarkably recalls. The city wall, which has been traced, encloses 170 ac., excavated portions of which include the forum, basilica, baths and numerous houses. Hill camps were fortified by the Romans at Chesterton Walls, Nordy Bank and Norton. Villas have been partially excavated at the Lea near Pontesbury, Acton Scott and Linley Hall, while traces of square camps occur at Leintwardine (?Bravonium) towards Caerleon and at Oakengates (?Uxacona). The discovery of pigs of lead stamped with the name of the Emperor Hadrian (A.D. 117–138) proves that mining and smelting were carried on by the Romans in the Shelve district. The mines of Grit and Roman Gravels have considerable traces of ancient workings.

The district which is now Shropshire was annexed to the kingdom of Mercia by Offa, who in 765 constructed Wat's Dyke to defend his territory against the Welsh, and in 779 drove the king of Powys from Shrewsbury and secured his conquests by a second defensive earthwork known as Offa's Dyke, which, entering Shropshire at Knighton, traverses moor and mountain by Llanymynech and Oswestry, in many places forming the boundary line of the county, and finally leaves it at Bron y Garth and enters Denbighshire. (*See* Dr. Cyril Fox, "Archaeologia Cambrensis," June 1926, etc.) Anglo-Saxon village settlements occupy most of the county except the hills of the north-west and south-west. They are easily recognizable by the terminations "bury," "ton," and "ley," etc. The numerous Celtic place names in the hilly country of the north-west and south-west (*e.g.*, frequently recurring elements like "bettws," "pentre," "llan," and "tre") are an interesting feature.

The Danes in 874 destroyed the famous priory of Wenlock, said to have been founded by St. Milburg. In 912 Aethelflead, the lady of Mercia, erected a fortress at Bridgnorth against the Danish invaders, and in the next year at Chirbury. Mercia was mapped out into shires in the 10th century after its recovery from the Danes by Edward the Elder, and Shropshire is the sole Mercian shire which did not derive its name from its chief town. The Saxon Chronicle says that the king crossed the Thames in 1006 and wintered in Shropshire. In 1016 Edmund Aetheling plundered Shrewsbury and the neighbourhood.

After the Conquest Shropshire was bestowed on Norman proprietors, pre-eminent among whom is Roger de Montgomery, the 1st earl of Shrewsbury. At this period a large part of Shropshire was covered by its vast "forests," the largest of which, Worf Forest, at its origin, was at least 8 m. by 6 m., and became a favourite hunting-ground of the English kings. The forest of Wrekin, or Mount Gilbert as it was then called, covered that hill and extended eastward as far as Sheriff Hales. Other forests were Stiperstones, the jurisdiction of which was from time immemorial annexed to the barony of Caus, Wyre, Shirlot, Clee, Long Forest and Brewood.

The constant necessity of defending their territories against the Welsh prompted the Norman lords of Shropshire to such activity in castle-building that out of 186 castles in England no fewer

than 32 are in this county. Of these the most famous are Ludlow, founded by Roger de Montgomery; Bishop's Castle; Clun Castle; Cleobury Castle; Caus Castle; Rowton Castle and Red Castle. Other castles were Bridgnorth, Corfham, Holgate, Pulverbatch, Quatford, Shrewsbury and Wem.

One of the finest examples of moated manor houses is the 13th century Stokesay Castle near Craven Arms. It has a notable 14th century half-timbered gatehouse.

Among the Norman religious foundations were the Cluniac Priory at Wenlock, re-established on the Saxon foundation by Roger Montgomery in 1080; the Augustinian abbey of Haughmond founded by William Fitz-Alan; the Cistercian abbey of Buildwas, now a magnificent ruin, founded in 1135 by Roger, bishop of Chester; Shrewsbury Abbey, founded in 1083 by Roger de Montgomery; the Augustinian abbey of Lilleshall, founded in the reign of Stephen; the Augustinian priory of Wombridge, founded before the reign of Henry I.; the Benedictine priory of Alberbury founded by Fulk Fitz-Warin in the 13th century; and Chirbury Priory founded in the 13th century.

In post-Roman times the history of Shropshire is largely concerned with the constant incursions of the Welsh from beyond Offa's Dyke. The Norman castles already enumerated, guarding the approaches to Wales (*see* Montgomeryshire), formed an inner and outer line of defence; but the western half of the county, down to the time of Elizabeth, probably had little permanent population outside the castle towns and moated farms. For centuries whole areas were waste land. When peace came in the 16th century it was chiefly Welshmen who began to occupy the rich plains. This infiltration has persisted down to modern times. Oswestry, Clun and Shrewsbury were more than once plundered and burnt, *e.g.*, by Llewellyn the Great in the 13th century. It was then that Edward I. determined to remove the Welsh menace and in 1282 his "conquest" of Wales and his restoration of the border castles brought a measure of peace to the county.

Meanwhile the Shropshire lords were actively concerned in the more national struggles. At Acton Burnell in 1283 was held the parliament which passed the famous Acton Burnell statute. During the Percy rebellion a battle at Shrewsbury (1403) saw the defeat and death of Hotspur. About 1473 a "Council of the Marches" was established to administer the Welsh borderland. It lasted for two centuries, with its headquarters at Ludlow, and did much good in suppressing border riots. During its term the Union of England and Wales was effected by parliament, and the boundaries of the Shire of Salop were fixed. On the outbreak of the Civil War in the 17th century the majority of the Shropshire gentry declared for the king. A mint and printing press were set up in Shrewsbury. The town was forced to surrender in 1644, and the royalist strongholds of Ludlow and Bridgnorth were captured two years later.

One of the first acts of William and Mary was to abolish the Council of the Marches. About a century later came the agricultural and industrial revolutions which so greatly affected the occupations and distribution of the population. The county is mainly indebted to geographical and geological causes for its industrial life both in the past and in the present, proximity to Wales having largely influenced the ancient cloth trade, while the richness of its mineral resources has resulted in the coal and iron industry of to-day.

The history of the cloth trade in Shropshire centres in Shrewsbury (*q.v.*), where the drapers occupied a singular position in drawing their revenue not from their own manufacture, but from the distant markets of Oswestry, Welshpool and Montgomery, though the goods were dressed by the middlemen of Shrewsbury. The beginnings of the wool trade go back to the 13th century, when the interests were of municipal importance, Shrewsbury, Ludlow, Oswestry and Bridgnorth being the leading Shropshire centres. By the 16th century Shrewsbury drapers had many privileges and with geographical advantages the town became the chief market for an area including Merionethshire, Montgomeryshire and parts of Denbighshire.

It is to this period of prosperity in the border, when the Council of the Marches had established order and commerce and population increased, that we trace the spread of the custom of constructing houses with timber frames, many of which are to-day world-famed for their beauty and elegance. Such "black and white" houses, large and small, give a peculiar charm to the border counties from Cheshire to Gloucestershire. In Shropshire the best examples are in those towns mentioned above; while country houses include Pitchford Hall near Acton Burnell (cir. 1570) and Park Hall near Oswestry (1560) which was, however, nearly destroyed by fire in 1918. While some houses of this type date from the 15th century, most are of 16th century date, when much building in stone and brick was also carried on, Benthall Hall (1580), Shipton (1589) and Condover (1590) being fine Elizabethan country houses. By the end of the 18th century the Shropshire cloth trade had declined, new markets having been established in Wales with better means of communication, the improvement of roads and the construction of canals.

Within the county the River Severn had long been a source of food and a highway of industry. The salmon and eel fisheries of the river are famous, and Shrewsbury fishermen retain the primitive "coracle." In mediaeval times the religious houses were conveniently placed near the river (*e.g.*, Buildwas, Shrewsbury and the White [Alberbury] Abbeys), both for fishing and for water communication. Thus Buildwas Abbey exported wool to Italian markets in the 13th and 14th centuries.

At this time the Severn was navigable nearly up to Welshpool, and Shrewsbury, Bridgnorth, Gloucester and Bristol were connected by brisk traffic, which persisted and at times flourished down to about 1850. Goods carried included coal, iron, lead ores, groceries, wool and timber. Nearly 400 barges were in use in 1758, Broseley alone having 87 vessels employed in the export of coal and pig and bar iron. But the river was not navigable for three or four months of the year, and as the ancient rules for maintaining the waterway, etc., fell into disuse the barge traffic decayed until, by 1900, it had practically disappeared.

In 1792 the Shropshire canal was completed, in which the inclined plane system invented by Mr. William Reynolds of Ketley was first successfully used instead of locks. Local transport of coal and iron was greatly assisted by this and other canals in the industrial districts. The Shropshire Union canal was designed by Telford. By means of this system, now defunct, it was possible to pass from the Severn to the Dee, Mersey and Stour. With the building of railways the canals gradually fell into disuse, though they were still used for heavy goods up to the World War.

The railway systems show a remarkable concentration on Shrewsbury, whose position as a route centre they have greatly enhanced. The principal line is that of the G.W.R. from Albrighton to Shrewsbury, Chirk and Birkenhead. Other main railways run from Shrewsbury to Welshpool, to Whitchurch, to Bridgnorth and Bewdley and to Ludlow. The L.M.S. line from Stafford skirts the north-west border of the coalfield to Wellington. From Craven Arms a railway line (L.M.S.) runs to Knighton and Builth Road. There are numerous local lines.

The chief industries are coal-mining, iron founding and the making of china, tiles and bricks. They are concentrated in the "Coalfield Peninsula" from Broseley to Lilleshall. Other coalfields are those of Chirk, the Forest of Wyre, Hanwood and the Clee hills. Iron smelting is an old industry at Coalbrookdale, charcoal having been used long before the beds of coal, found interbedded with the ironstone, were utilized. Abraham Darby of Coalbrookdale first applied pitcoal to the reducing of ironstone. Under the Darbys and Reynolds the Shropshire works gained a reputation both for their large size castings and for their delicate "hollow" work. The first cast-iron bridge ever erected (1779), designed by Abraham Darby, spans the Severn near Coalbrookdale and gives its name to the town of Ironbridge. The manufacture of cast and wrought iron still continues on a smaller scale.

Very important industries early developed from the exploitation of the coal-measure clays. Bricks, white, red and blue, are largely made, and roof tiles, fire bricks and encaustic tiles. Coarse pottery, earthenware and drain pipes are also made from local clays, while the Coalport china works and the once famous Broseley clay

pipes are typical of other aspects of the industry, though Kaolin clay is imported for these old industries. Other clays used for brick-making include the marls of the Upper Trias, boulder clay and river alluvium. The chief building stone is the upper Triassic sandstone, the most famous quarries being at Grinshill, whence came the stone of Buildwas Abbey (*e.g.*) in the 12th century. Many other rocks, including limestone, igneous rocks and conglomerates, are locally used as building material. The dolerite or "dhu-stone" which caps the Clee hills is a well-known road metal.

For the most part, however, Shropshire remains an agricultural county. More than four-fifths of its area is under cultivation. On the sandy soils and loams of the north barley and oats are the chief crops, and sugar beet is increasingly grown. Wheat is grown especially on the west and south sides. There are considerable tracts of hill-pasture in the south, where Shropshire and Kerry Hill Sheep (the latter related to the old Clun Forest breed) are reared. "Cheshire" cheese is made on the northern plain from Market Drayton to Ellesmere. The cattle are chiefly Shorthorns, but Herefords are preferred for fattening. The prosperous market towns of Shrewsbury, Oswestry, Wellington, Ellesmere and Ludlow (*q.v.*) serve as centres for the agricultural regions. The county contains considerable areas of coppice and woodland, modern plantings of conifers occurring chiefly in the south, while the northern plains have much hedgerow timber and beautiful clusters of typical Scots pine. Part of the ancient Forest of Wyre extends into the Cleobury Mortimer area in the south-east.

The area of the ancient county is 859,516 ac., with a population of 244,162 in 1931. The area of the administrative county is 861,800 ac. or 1,343 sq.m. The dioceses of Lichfield and Hereford divide the county between them, but a few parishes in the west are in the diocese of St. Asaph. The municipal boroughs are Bishop's Castle, Bridgnorth, Ludlow, Oswestry, Shrewsbury and Wenlock.

There are 14 hundreds, 267 civil parishes and 284 ecclesiastical parishes or districts. The county is in the Oxford circuit and assizes are held at Shrewsbury. It has one court of quarter sessions and is divided into 18 petty sessional divisions. For purposes of parliamentary representation there are four divisions, those of Ludlow, Oswestry, Shrewsbury and the Wrekin, each returning one member.

Hartshorne, *Salopia Antiqua* (London, 1841); Fletcher, *Religious Census of Shropshire in 1676* (1891); W. W. Watts, *Shropshire, The Geography of the County* (Shrewsbury, 1919); Shropshire Archaeological and Natural History Society (1877, etc.).

SHROVE TUESDAY, the day before Ash Wednesday, the first day of Lent, so called as the day on which "shrift" or confession was made in preparation for the great fast. Shrove Tuesday is called in French *Mardi gras,* "Fat Tuesday," in allusion to the fat ox which is ceremoniously paraded through the streets. The Germans know it as *Fastendienstag.* It is celebrated in Catholic countries, as the last day of the carnival, with feasting and merrymaking, of which, in England, the eating of pancakes alone survives as a social custom, the day having been called at one time "Pancake Tuesday."

In the United States the festival season preceding Lent, particularly associated with New Orleans, La., is known as the Mardi Gras. Properly speaking, the season begins with the New Year and terminates with parades, pageantry and a ball on Shrove Tuesday. This carnival season, of ancient and somewhat obscure origin, was introduced into America by the French colonists. Celebrations, accompanied by masking, are recorded as among the activities of the soldiers at Ft. Louis de la Louisiane (1702–10), on the first site of Mobile, Ala. Similar festivities were observed by the residents of New Orleans from its foundation, and were continued during the Spanish control of Louisiana. The custom was retained after the United States purchased that territory, but it was not until 1857 that a group of former residents of Mobile, Ala., where masked parades had long been a prominent feature of the celebration, organized "The Mystick Krewe of Comus," and produced the first spectacular parade with floats at New Orleans. Since that date "King Rex" has yearly ruled over the city on Shrove Tuesday or Mardi Gras, and appeared in the streets accompanied by his "Mystick Krewe of Comus." In the evening the frolic season terminates with brilliantly illuminated pageantry, depicting scenes from literature or history, followed by a ball.

See P. J. Hamilton, *Colonial Mobile* (1910); L. De V. Chaudron, *Mobile Mystics and the Story of the Mardi Gras* (Mobile, 1910); J. S. Kendall, *History of New Orleans* (1922).

SHUFFLE-BOARD or **SHOVEL-BOARD** (originally "shove-board"), the game in which wood or metal discs are "shoved" by the hand or with an implement so that they shall come to a stop on or within certain lines or compartments marked on the "board"—a table or a floor. It was formerly very popular in England, especially with the aristocracy, under the names *shove-groat, slide-groat* and *shovel-penny,* being mentioned as early as the 15th century. It was a favourite pastime at the great country houses, some of the boards having been of exquisite workmanship. That at Chartley hall, in Staffordshire, was over 30ft. long and was made up of 260 pieces. Shuffle-board enjoys considerable vogue in the United States. The board is from 28 to 30ft. long and from 18 to 20in. wide, of pine, poplar or white wood, with a gutter 4½in. wide extending entirely round the board. The surface is slightly sanded and sometimes oiled. About 5in. from each end of the board is drawn a line called the *deuce line.* Each side, whether composed of two or four persons, uses four discs of polished brass or iron, generally about 2in. in diameter and ½in. thick. When two persons play they shove first from one end of the board and then from the other; but when four play one of each side remains permanently at each end. The discs, four of which are marked A and four B, are shoved alternately by each side. A disc resting between the deuce line and the end of the board is *in* and scores two. One protruding over the end sufficiently to be lifted by the finger is called a *ship* and counts three. A disc resting on the board but not crossing the line counts one. In scoring only the best of the eight discs counts, unless one side has two that are better than any of their opponents', in which case both count. The side first scoring 21 points wins.

A variety of shuffle-board is very popular as a deck game on board steamers and yachts. It is played by pushing wooden discs by means of crutch-shaped cues, or *shovels,* into which the discs fit, so that they come to a stop within the lines of a large rectangle drawn with chalk on the deck and divided into squares numbered from 1 to 10 with an extra square nearest the player, numbered –10. The game is usually 21 points.

SHUKRIA: *see* ARABS.

SHUMEN, incorrectly SHUMLA, a town of Bulgaria, 50 m. W. of Varna, on the Sofia-Varna railway. Pop. (1926) 25,315, about one-third being Muslims. The town is built within a cluster of hills, northern outliers of the eastern Balkans, which curve round it on the west and north in the shape of a horse-shoe. As a centre of communications in the southern Danube valley, Shumen has great strategical importance. In the picturesque upper quarter is the magnificent mausoleum of Jezairli Hassan Pasha. The principal mosque is the largest in Bulgaria. The town has an important trade in grain and wine, besides manufactures of silk, red and yellow slippers, ready-made clothes, richly embroidered dresses for women, and copper and tin wares.

In 811 Shumen was burned by the emperor Nicephorus, and in 1087 besieged by Alexius I. In 1387 it was taken by the Turks. In the 18th century it was enlarged and fortified. Three times, in 1774, 1810 and 1828, it was unsuccessfully attacked by Russian armies. The Turks consequently gave it the name of Gazi ("Victorious"). In 1854 it was the headquarters of Omar Pasha and the point at which the Turkish army concentrated (*see* CRIMEAN WAR). On June 22, 1878, it capitulated to the Russians.

SHUMLA: *see* SHUMEN.

SHURUPPAK (modern Fara), an ancient city of Mesopotamia situated on the old course of the Euphrates 50 m. N.W. of Lagash in 31° 30′ N., 45° 30′ E. The city is of special importance in the prehistoric period. It was famous as the home of Zuisudu, the hero of the flood story, and the Semitic version actually places the construction of the ark and all the details of the story at Shuruppak, which with Sippar, Larak and Eridu are mentioned as the only cities before the flood. The town entirely

disappears from ancient records after the last dynasty of Ur, somewhere before 2300 B.C. Excavations have thrown considerable light on the earliest period. Burials have been found with the bodies folded in the so-called embryonic position and wrapped in a reed mat. Clay coffins have also been found with the mat burials. The goddess of the city was Ninlil, the earth mother of Nippur, and the chronology of the town was kept by calling the year after the annual magistrate. A few tablets have been found before the time of Urnina. The town probably belonged to the southern kingdom of Lagash, and Langdon believes that it is not included in the dynastic list because there was the contemporary kingdom of Unzi of Akshak. He suggests that there was an extensive Sumerian kingdom at Lagash for a short period before Urnina, and cites the evidence of the similarity of legal terms in the business documents of Shuruppak, Lagash and Akkad.

SHUSHTAR, a town in the province of Khuzistan, Persia, about 32° N. and 49° E., in the angle formed by the bifurcation of the Karun River into the Ab i Gargar and Ab i Shatait, some 40 m. below the point where the Karun debouches into the plains from the Bakhtiari mountains. The town covers a larger area than its estimated population of 20,000 warrants, being in large part in a ruinous and deserted condition; it has indeed been described as one of the most tumble-down places in all Persia. Many of the houses, of stone and brick, have cellars, called *shewadan,* in which the inhabitants shelter in the excessive heat of summer, which on occasion reaches 128° F. The sanitary conditions are very bad. The bazaar is a poor one and the few permanent shops are to be found in the street leading through the centre of the town to the Pul i Bulaiti (bridge). Even the mosques are devoid of special architectural features except perhaps the oldest one built under the Abbasids. On the other hand, the citadel, or Qal'ah Salasib, is a most imposing though ruinous mass, crowning the cliff, covering an area 350 by 150 yd., and described by Sykes as "the finest fort he had ever seen in Persia." The town has three exits: (a) westward over the bridge to Dizful, now interrupted owing to the bridge being broken down in the middle, its place being taken by a ferry; (b) southward by the Pul i Lashkar road to the Miyanab (the name of the fertile tract between the Gargar and Shatait branches); and (c) over the great dam to the suburb of Bulaiti.

Water Works.—Shushtar is most famed for the great works constructed in ancient times for the disposal of the voluminous water of the Karun river. These comprise (a) the Ab i Gargar Canal (the Masruqan of the middle ages). (b) The great barrage called the Band i Qaisar which is thrown across the Ab i Shatait (the principal arm of the river) west of the town. It is about 440 yd. long and supports a bridge, the Pul i Dizful (previously referred to). (c) The canal called Minau, which takes off above the barrage by a tunnel cut out of the rock on the western side of the town below the citadel, the purpose of which was to irrigate the Miyanab. Tradition says that the Minau Canal was built by Dara the Great and that it was Ardashir I. (the Sasanid) who began to construct the barrage after the canal mouth had dried up. The barrage was only completed under Shapur II. by the Roman prisoners with Valerian II. The Ab i Gargar was first dug simply to divert the volume of the water of the main river; the Band i Qaisar was then constructed, and the bed of the river above the barrage was paved with huge stone slabs bound with iron, to prevent further erosion. This paving was called *Shadurwan,* a term also applied to the barrage itself. Ultimately, a new barrage is said to have been built across the Gargar.

Population and Industries.—The population is a mixture of Arab and Iranian or proto-Iranian elements, known locally as Shushtaris, speaking a patois of their own and all Shia Mohammedans. A few Bakhtiaris are the only other element. Travellers speak of the disagreeable and fanatical character of the inhabitants; but among the Persians their devoutness has earned for the town the honorific title of *Dar al Muminin.* Its position gives the town a considerable commercial as well as strategic importance. It stands on a trunk road from Mohammerah via Ahwaz, Dizful, Khurramabad and Qum to Tehran, in large part fit for motor traffic. The industries are carpet weaving called *gilim,* the making of woollen cloths for *abas,* coarse cotton canvas and turbans, glazed earthenware, pack and riding saddles; copper, brass and silver-work; tanning and dyeing. A project was under consideration in 1928 for hydro-electric development by utilizing the water of the Karun near Shushtar.

History.—In the Umayyad period Shushtar became a stronghold of the Kharijites, one of the earliest religious sects of Islam. Under the Caliphs it was the capital of one of the seven provinces into which Khuzistan was then divided. When Baghdad became the centre of the empire, Shushtar, by its proximity was advantageously affected. The town was conquered by Timur and remained in the hands of the Timurids until 1514, when it fell to a Shia dynasty of Sayyids under the suzerainty of the Safavids and became a centre of Shia propaganda. In the beginning of the 19th century it was governed by a son of Fath Ali Shah who restored the barrage and the bridge; and at this time it was said to have a population of 45,000.

SHUVALOV (shōōv'ạ-lŏv) or SCHOUVALOFF, **PETER ANDREIVICH,** COUNT (1827–1889), Russian diplomatist, was born in 1827. In 1864 Court influence secured for him the appointment of governor-general of the Baltic Provinces, and in 1866 he was made head of the political police in Russia. In 1873 he was sent on a mission to London, ostensibly to arrange matters in dispute between England and Russia in Central Asia, but also to arrange the marriage of the grand duchess Marie Alexandrovna with the duke of Edinburgh, which took place in January of the following year. The success of this mission led to the appointment of Shuválov as ambassador to London; and he justified his selection by the extraordinary diplomatic ability he displayed during the Russo-Turkish War of 1877–78 and the subsequent negotiations, when the relations between Russia and Great Britain were strained almost to the point of rupture. After the publication of the treaty of San Stefano, which seemed to render a conflict inevitable, he concluded with Lord Salisbury a secret convention which enabled the two powers to meet in congress and find a pacific solution for all the questions at issue. When it became known that the San Stefano arrangements were profoundly modified by the treaty of Berlin, public opinion in Russia condemned him as too conciliatory, and in the autumn of 1879, when Bismarck assumed an attitude of hostility towards Russia, Count Shuválov, who had been long regarded as too amenable to Bismarckian influence, was recalled. He died at St. Petersburg in 1889. (D. M. W.)

SHWEBO, town and district in the Sagaing division of Burma. The town is situated in the midst of a rice plain, 53 m. N.E. from Mandalay by rail. Pop. (1921) 10,605. It is of historic interest as the birthplace and capital of Alompra, the founder of the last Burmese dynasty. After British annexation it became an important military cantonment; but there is no longer any garrison. The area of the district is 5,714 sq.m.; pop. (1921) 391,284, showing an increase of 34,921 in the decade. It lies between the Katha, Upper and Lower Chindwin and Mandalay districts. The Irrawaddy forms the dividing line on the east. The physical features of the district vary considerably. The Minwun range runs down the whole eastern side, skirting the Irrawaddy. In the north it is a defined range, but at Sheinmaga, in the south, it sinks to an undulation. West of the Mu river, in the centre of the district, there is a gradual ascent to the hills which divide Shwebo from the Upper Chindwin. Between these ranges and on both sides of the Mu is a plain, unbroken except for some isolated hills in the north and north-east and the low Sadaung-gyi range in the south-east. The greater part of this plain is a rice-growing tract, but on the sloping ground maize,

millets, sesamum, cotton and peas are raised. A good deal of sugar is also produced from groves of the *tari* palm. The Mu river is navigable for three months in the year, from June to August, but in the dry season it can be forded almost anywhere.

Extensive irrigation works existed in Shwebo district, but they fell into disrepair in King Thibaw's time. Chief of these was the Mahananda lake. The old works have been restored and extended, and in 1906 the main canal was formally opened. The district is on the northern borders of the dry belt; the southern tracts have between 25 and 40 in. of rain, the northern tracts rather more. The Sagaing-Myitkyina railway runs through the heart of the district, and a railway was recently opened connecting Yè-u (pop. 2,742 in 1921) with the Chindwin river port of Mônywa.

SHYOK, a large tributary of the upper Indus, which rises near the southern foot of the great pass of the Karakoram range, on the route from Leh to Yarkand. Two important streams, with affluents, flow south from the Karakoram until they reach one of the great longitudinal troughs north of and parallel to the Himalaya system and the Indus-Brahmaputra line, and north of the latter. They both join the stream along this trough which, flowing north-westwards, makes a very sharp bend, and thus joins the Indus in Baltistan. Below a station called Yapchan, situated some 35 m. S. of the Karakoram pass, at a junction of valleys, the river bed begins to encase itself in a deep, narrow gorge, in which, normally, it receives the drainage of the Little Khumdan glacier. In 1926 this glacier pushed its way into and across the gorge, and thus built an ice-dam 480 ft. high. The ice-dammed lake above had grown to a length of 9 m., an average breadth of 1,000 yd. and a depth of 25 ft. by July 1928. At the beginning of August the level of the lake rose steadily, and on Aug. 4, 1928, a crack in the dam had developed. This caused widespread anxiety, and elaborate beacon-signalling arrangements were improvised and some villages below were evacuated. The alarm was intensified as a beacon fire was seen, but it proved to be a fire kindled by a Yarkandi caravan. Subsequent reports showed that the lake was leaking slowly through the crack in the ice-dam, and the danger of flood passed away.

SIALKOT or **SEALKOTE,** a town and district of British India, in the Punjab. The town, which has a station on the North-Western railway, is 72 m. N.E. of Lahore. Pop. (1921) 70,619. It is a military cantonment, being the headquarters of a brigade. There are remains of a fort dating from about the 10th century; but the mound on which they stand is traditionally supposed to mark the site of a much earlier stronghold, and some authorities identify it with the ancient Sakala or Sagal. The town has an extensive trade, and manufactures of sporting implements, boots, paper, cotton, cloth and shawl-edging.

The District of Sialkot has an area of 1,796 sq.m. It is an oblong tract of country occupying the submontane portion of the Rechna (Ravi-Chenab) Doab. Sialkot is above the average of the Punjab in fertility. The upper portion is very productive; and the southern portion, though less fertile, now receives irrigation from the Upper Chenab Canal. Sialkot is reputed to be healthy; it is free from excessive heat, judged by the common standard of the Punjab; and its average annual rainfall varies from 35 in. near the hills to 22 in. in the parts farthest from them. The population in 1921 was 937,823. The principal crops are wheat, barley, maize, millets and sugar-cane.

The early history of Sialkot is closely interwoven with that of the rest of the Punjab. It was annexed by the British after the second Sikh war in 1849; since then its area has been considerably reduced, assuming its present proportions in 1867.

SIAM (Muang Thai), an independent kingdom, in the Indo-Chinese or Further India Peninsula, with an area of about 220,000 sq.m. (For map, *see* Indo-China.) The country contains four natural regions:

(1) *North.* About 60,000 sq.m. in area, a series of parallel ranges, lying north and south, and rising from mere gently sloping acclivities in the south, to precipitous masses in the north. Between these ranges of limestone and red sandstone flow four streams, turbulent and shallow in their upper reaches, but slow-moving and deep where they near the points of junction. Of these the Menam is the largest, deepest and most sluggish. The districts watered by the lower reaches of the four rivers are fertile and contain a considerable population of Siamese. Farther north live the Laos, scattered in villages along all the river banks, and numerous communities of Shan, Karen, Kamoo and other tribes in the uplands and on the hill tops.

(2) *East.* About 70,000 sq.m. practically a huge basin, the bottom of which is a plain lying from 200 to 300 feet above sea-level, and the sides hill ranges rising to between 1,000 and 2,000 feet. The plain is mostly sandy and almost barren, subject to heavy floods in the rainy season and to severe drought in the dry. The hills, composed of limestone, red sandstone, etc., are clothed with a thin shadeless growth of stunted forest which only here and there assumes the characteristics of ordinary jungle. Nearly 2,000,000 people, mixed Siamese, Lao, and Cambodian, probably amongst the poorest peasantry in the world, occupy this inhospitable region.

(3) *Central.* Estimated area, 50,000 sq.m. This is the heart of the kingdom, the home of the greater part of its population and the source of nine-tenths of its wealth. It is a great alluvial plain flanked by high mountains on the west, inclining gently to the sea in the south and round the inner Gulf of Siam and with a long strip of mountainous seaboard stretching out to the south-east. The western range, whose highest peak is Mogadok (5,000 ft.) forms the boundary between central Siam and Burma. The eastern and south-eastern ranges also have peaks of from 3,000 to 5,000 feet. The rivers, with the exception of the Menam Chao Phaya, the principal river of Siam, are short and of little value except for traffic by small native boats. The Menam Chao Phaya flows from the point where it is formed by the junction of the rivers of northern Siam almost due south for 154 m., when it empties itself into the inner gulf. In the neighbourhood of Chainat, 40 m. below Paknam Poh, it throws off three branches, Menam Noi and the Lopburi, which rejoin the parent stream much lower down, and the Suphan which has its own outlet to the sea. About the centre of its course, the main river is joined by its only tributary, the Nam Sak, which drains the most easterly part (the Pechabun valley) of north-east Siam. The Menam Chao Phaya is a deep, fairly rapid river, subject to a regular rise and flood every autumn and is affected by the tide 50 m. inland. It is navigable for 20 m. by vessels of over 1,500 tons and, if it were not for the enormous sand bar at the mouth, ships of almost any size could reach Bangkok. (*See* Bangkok.) Vessels up to 300 tons and 12 ft. draught can ascend the river 50 m. and more, and beyond that point large river boats and deep-draught launches can navigate for many miles. The river is loaded with silt which, during the flood season, is deposited on the plain. With the exception of the forest growth on the slopes of the bounding hills the whole of central Siam is open rice-land, alternating with great stretches of grass, reed jungle and bamboo scrub, much of which is under water for quite 3 months each year.

(4) *Southern.* Area about 20,000 sq.m. This comprises that part of the Malay Peninsula belonging to Siam. It is a narrow strip at the north but widens out to the south where the habitable section consists of the lower slopes of the range with the valleys and small alluvial plains which lie between its spurs. The remainder is mostly covered with dense forest containing several kinds of valuable timber. The coast, both east and west, is much indented and studded with islands. The rivers are small and shallow. The highest mountain is Kao Luang, an almost isolated projection over 5,000 feet high, round the base of which lie the most fertile lands of this section, and near which are situated a few small towns, such as Bandon, and many villages.

Climate.—Siam has a monsoon climate—the wet season, May to October, corresponding with the prevalence of the S.W. monsoon in the Bay of Bengal. The full force of the monsoon is broken by the western frontier hills so that the average rainfall of Bangkok is about 50 inches and of Chieng Mai about 42 in. The temperature during the wet season averages 65–75° F at night and 75–85° F by day; but breaks in the rains occur which are hot and steamy. The cool season begins with the commencement of the N.E. monsoon in November. Siam then enjoys cool

nights (40–50° F) and day temperatures rarely as high as 90° F in the shade; but the east coast of the Malay Peninsula receives the full force of the north easterly gales. In February the northerly current begins to lose strength and the gradual heating of the land produces local sea breezes along the coast. Inland, temperature rises to over 100° F, but the extreme continental heats of India are unknown. The comparative humidity of the atmosphere makes the climate trying for Europeans.

Flora.—In its flora and fauna Siam combines the forms of Burma and the Shan States with those of Malaya and Cambodia. The coast region is characterised by mangroves, *Pandanus*, rattans and similar palms; the central region by rice fields, coco-nut and areca palms, and tropical economic plants; the temperate uplands of the interior are forested and contain some Himalayan and Japanese species—oaks, pines, chestnuts, peach and apple trees, raspberries, honeysuckle, vines, saxifrages, Cichoraceae, anemones and Violaceae; there are many valuable timber trees—teak sappan, eagle-wood, wood-oil (Hopea), and other Dipterocarpaceae, Cedrelaceae, Pterocarpaceae, Xylia, ironwood and other dye-woods and resinous trees, these last forming in many districts a large proportion of the more open forests with an undergrowth of bamboo. The chief products of the plains are rice (the staple export), pepper, sirib, sago, sugar cane, coco-nut, betel, palmyra or sugar and attap palms; banana, durian, pommelo, guava, bread fruit, mango, pineapple, custard apple, mangosteen and other fruits.

Fauna.—Among the big game animals are the elephant, tiger, leopard, fishing-cat, leopard-cat and other species of wild cat, honey-bear, large sloth-bear, and one- and two-horned rhinoceros. Wild cattle include the gaur, banting and water buffalo. The goat antelope, several varieties of deer, wild pig, rats, bats and monkeys also exist. There are 56 varieties of snakes, of which only 12 are poisonous. Crocodiles haunt the rivers and estuaries. Fresh and salt water fish are numerous and, after rice, form the main food of the population. The country is rich in birds many of which are common to Burma and Cambodia.

Inhabitants.—The estimated population for 1925–26 was 9,831,000. Of this about 3,800,000 are Siamese, about 3,650,000 Laos, about 500,000 Chinese, 400,000 Malays, and the rest Cambodians, Burmese Indian, Mon, Karen, Annamite, Kache, Lawa and others. There are about 1,800 Europeans and Americans mostly resident in Bangkok. The Siamese inhabit central Siam principally, but extend into the nearer districts of the other sections. Laos predominate in northern and eastern Siam; Malays mingle with Siamese in southern Siam; Chinese are everywhere but mostly in the towns. Bangkok, the capital, with some 350,000 inhabitants, is about one-third Chinese; in the suburbs are settlements of Mons, Burmese, Annamites and Cambodians, descendants of ancient prisoners of war. The Eurasian population is very small compared with that of other large Eastern cities. Of the tribes in the mountains some are remnants of very ancient inhabitants, probably of the Mon-Khmer family, who were supplanted by a later influx of more civilised Khmers from the southeast, the fore-runners and part ancestors of the Siamese, and were still farther thrust into the remoter hills when the Lao-Tai descended from the north. Of these the principal are the Lawa, Lamet, Ka Hok, Ka Yuen and Kamoo; the last four collectively are known to the Siamese as Ka. Other immigrant tribes include the Karens (about 60,000) of the western frontier range, offshoots from the main tribes on the Burma side of the range and possibly of Burma-Tibetan origin; the Lu, Yao, Yao Yin, Meo and Mussur, who have Yunnanese characteristics, and possibly entered northern Siam since the beginning of the 19th century; a small tribe called Chong, behind Chantabun; and the Sakei and Semang in the higher ranges of southern Siam. The last three have Negrito characteristics and may represent a race far older even than the ancient Ka.

Racial Characteristics and Dress.—The typical Siamese is of medium height, well formed, with olive complexion, darker than the Chinese, fairer than the Malays; eyes well shaped but slightly inclined to the oblique; broad flat nose; prominent lips; face wide across the cheek bones; chin short. A thin moustache is common; any beard is plucked out. Hair is black, coarse and cut short. Lips usually deep-red and teeth black as a result of chewing betel. The children are pretty but early lose their charm. The position of women is good. Polygamy is common only among the upper classes but the first wife is the head of the household. The Siamese are gentle, patient, law-abiding, kindly and hospitable to strangers, light hearted, sympathetic, and little given to quarelling or violent crimes. They are able, intelligent farmers but as they do not care for any other than agricultural labour, most of the industries and trades are in the hands of the Chinese. The national costume is the *panung*, a piece of cloth 1 yd. wide and 3 yd. long. The middle of it is passed round the body, covering it from the waist to the knees, and is hitched in front so that two ends of equal length hang down; these being twisted together are passed back between the legs, drawn up and tucked into the waist at the middle of the back. The *panung* is worn by both sexes but the women supplement it with a scarf worn round the body under the arms. Among the better classes both sexes wear also a jacket buttoned to the throat, stockings and shoes, and all the men, except servants, wear hats.

The staple food is rice and fish. Meat is eaten, but as the slaughter of animals is against Buddhist tenets, is not often obtainable, with the exception of pork, killed by Chinese. Men but not women smoke. Everybody chews betel. The principal pastimes are gambling, boat-racing, cock- and fish-fighting and kite-flying, and a kind of football.

Slavery has been gradually abolished by a series of laws. No such thing as caste exists and low birth is no insuperable bar to the attainment of the highest dignities. There are no hereditary titles, those in use being conferred for life only and being attached to some particular office.

Towns.—Siam has very few towns with a population of over 10,000, the majority being scattered townships and villages; the capitals of provinces are often only a few houses gathered round the market place, the offices and the governor's residence. The more important places of northern Siam include Chieng Mai (*q.v.*) the terminus of the Northern railway; Raheng, a timber station and the starting point of a Burmese trade route; Pitsanulok of historical interest and a centre of agricultural activity. In Eastern Siam the only towns of importance are Korat, the centre of a silk weaving industry; Ubon, the future terminus of the Eastern railway, and Nong Kai, an ancient place on the Mekong river. In Central Siam after Bangkok and Ayuthia are Pak Nam, with naval fortifications at the entrance to the Menam river; Paklat, a town of Mons, descendants of refugees from Pegu; Nontaburi, a big market centre; Lopburi, the last capital before Ayuthia and the residence of kings during the Ayuthian period, a city of ruins but now re-awakening as a railway centre. To the west of the Menam Chao Phraya are Suphanburi and Ratburi, ancient cities; Pechaburi (the Piply of early travellers); and Nakon Patom (Phrapatum) with its huge pagoda on the site of the capital of Sri Wichaiya, a kingdom of 2,000 years ago, and now a place of military, agricultural and other schools. To the east in the Bang Pakong basin and on the eastern shore of the Gulf are Petriou; Bang Plasoi, a fishing centre; Rayong, Chantabun (*q.v.*) and Krat, which produce gems and pepper. In Southern Siam the chief towns are Puket, the centre of the tin mining of the country; Nakon Sri Tammarat and Patani with a good roadstead which attracted European traders in the 16th and 17th centuries.

Communications.—Central Siam is well supplied with water communications: east to west canals link the three main river systems and bring the farthest parts of the kingdom within touch with Bangkok. In 1903 a department of government was formed to control the canals, the traffic on which is so great that the collection of a small toll more than pays for all maintenance expenses. The low level of the land, the soft soil, the absence of suitable road building material prohibits road construction but a bureau of roads and highways, organized by the railway department hopes to develop a policy of road construction whereby highways will serve as feeders to the railways at the main trading centres. In the mountainous country of northern and southern

Siam, road building is again difficult, and travelling in the remoter parts is still a matter of much discomfort.

In 1892 the construction of the first State Railway from Bangkok to Korat was undertaken. In 1926, 1,631 miles of State railways were in operation and 281 under construction. There were also 66 miles of private lines. Bangkok is the terminus of all main lines. The main line to the north terminates at Chieng Mai; the southern line threads the Malay Peninsula to Padang Besor where it joins the Federated Malay States Railway from Penang and Singapore. A branch line from Haad Yai passes along the east coast to Sungei Golok to join the Federated Malay States Railway. The north-eastern line to Korat is being extended to Khonkaen. The Korat-Ubon line is open as far as Buriram. The Eastern line runs to Aranya Pradesa on the Cambodian frontier.

Siam joined the Postal Union in 1885 since when there has been a steady and consistent improvement in postal, telegraphic and telephonic communication throughout the kingdom. Foreign telegraph lines communicate with Saigon, the Straits Settlements and Moulmein. Aviation has been adapted to postal communication and gives the remote provincial places a regular postal service. Dorn Muang, 22 km. north of Bangkok, is the chief aerodrome and has been used as a port of call by foreign aviators on long distance flights. Other towns have prepared landing places. Wireless installations under the control of the navy are found at Bangkok and Singora; another, under the control of the Post and Telegraph Department, is at Koh-Khan.

Agriculture.—Rice cultivation occupies almost all the inhabitants of Siam outside the capital. The sowing and planting season is from June to August and the reaping season from December to February; 40 or 50 varieties of paddy are grown and Siam rice is of the best in the world. Irrigation, until recently, was rudimentary and water supply depended chiefly on local rainfall. Under the advice, however, of an expert lent by the Government of India, the Siamese began work, in 1916, on the Prasak South Canal System. This, completed in 1924 at cost of £1,200,000, will eventually irrigate 240,000 acres. Work is now in progress on the Saphan programme. Other products of the plain include tobacco, pepper, coco-nuts (annual export of copra, 10,000 tons), sugar cane and many fruits. Live stock in 1926 included 8,389 elephants, 247,158 horses and ponies, 4,013,882 bullocks, and 4,216,127 buffaloes.

BY COURTESY OF THE BOARD OF FOREIGN MISSIONS OF THE PRESBYTERIAN CHURCH

SIAMESE ACTORS IN THE ELABORATE APPAREL COMMON IN PLAYS

Mining.—The minerals of Siam include tin, tungsten, wolfram, coal, iron, zinc, manganese, antimony, gold, silver, rubies, sapphires. Tin mining is carried on in the island of Puket, in the north of the Puket province and other parts of the Malay Peninsula where wolfram is also now being extracted in considerable quantities. Tin production in 1926–27 amounted to 10,140 tons. The Mining Department is well organised and employs several highly qualified English experts.

Timber.—Teak grows all over the hill district north of 15° N. but attains its best development in the west. The extraction of teak, almost entirely in British hands, employs a large number of people. The dry logs are floated down to Bangkok while large quantities are also exported via Burma. In 1926–27 the export of teak amounted to 59,339 tons, valued at £747,144. Other forest products include thingan wood (*Hopea odoratus*) used for boat building; damar oil from the *Dipterocarpus,* agilla wood, sapan, rosewood, iron wood, ebony and rattan. The forests are under the control of a Siamese conservator aided by British officials.

Commerce.—Commerce with India, China and Japan dates from the beginning of the Christian era and may be even earlier. European trade began in the 16th century. Over 85% of the foreign trade passes through Bangkok. Imports (1926–27) £15,935,121; exports £17,963,042. Siam is essentially an agricultural country and her exports comprise two main products—rice, £14,795,041; teak £747,144 (1926–27). Imports included cotton goods £2,292,638, gunny bags, £777,829, foodstuffs, £2,292,203, metal manufactures, £967,224, and machinery £326,219.

Government.—The government is an absolute monarchy. The executive power is exercised by the King advised by the Supreme Council of State and a Cabinet of 10 ministers. The Supreme Council of State is an advisory body, created by the present King Prajadhipok at the beginning of his reign, and consists of five princes of wide experience who possess the confidence of the country. It meets once a week, is presided over by the King, and considers extremely confidential matters and matters which affect the King personally and the royal family. By a Royal Decree of Jan. 10, 1895, a Legislative Council was established, but its functions have now been taken over by the Supreme Council of State, the Cabinet Council and the Department of Legislative Redaction of the Ministry of Justice. The Legislative Council seldom met but the Supreme Council and the Cabinet Council meet regularly.

For administrative purposes the country is divided, as from April 1, 1926, into 14 *montons* (or divisions), 13 of which are under a Lord-Lieutenant who derives his authority direct from the King, and exercises control over a number of subordinate governors in different parts of the monton; the Bangkok division (which includes the capital) is under the control of a Lord Prefect. The montons are subdivided into 79 provinces (Changwats) which are again subdivided into 413 districts (Ampurs) and 5,109 communes (Tambons). The policing of the montons is provided for by a gendarmerie of over 8,000 men and officers, a well-equipped and well-disciplined force. That of the suburban provinces is effected by branches of the Bangkok civil police.

Finance.—The revenue of Siam for 1908 was 58 million ticals or £4,300,000. In 1926–27 the revenue was £7,827,618 and the expenditure £7,808,362. The principal sources of revenue were

Land Tax	£ 911,459
Capitation Tax	863,636
Opium	1,433,671
Customs	930,118
Excise	901,197
Railways	645,800
Mines and Forests	641,818

Up to March 31, 1925, the amount spent on works of development was: construction of railways, £14,054,821; irrigation, £1,804,921; Bangkok waterworks, £394,344.

The unit of Siamese currency is the tical, a silver coin of fixed value of 1s.8d or 12 ticals to the £. Currency in use is mainly in the form of notes of which the first issue was made in 1902. In 1925 there was £10,735,305 worth of currency notes in circulation.

Weights and Measures.—The coinage furnishes the standard weight. 1 tical=15 grams; 4 ticals=1 Tamlung; 20 Tamlungs=1 Chang; 1 Picul or Hâp=60·48 kilograms=100 Catties of $1\frac{1}{3}$ lb., which is the catty usually employed in commerce.

The unit of length is the Wah. 1 Niew=·83 in.; 12 Niu=1 Keub (10 in.); 2 Keup=1 Sawk (20 in.); 4 Sawk=1 Wah (80 in.); 20 Wah=1 Sen (133 feet); 400 Sen=1 Yote (10 miles roughly). For square measure the unit is the Rai, ·39 acre, and for capacity, the Kanahan=$\frac{19}{20}$ litre.

In 1924 a law was passed for the introduction of the metric system which is to be compulsory in 1930.

Army and Navy.—All able bodied men are liable by the Military Service Act of 1917, to two years' service with the colours and for varying periods in the reserves. The army is divided into ten divisions. Aviation schools are in existence and a flying corps has been formed which is chiefly employed in development of civil aviation. The navy is small and consists of 5 gunboats, 3 destroyers, 4 torpedo boats and various small craft. One thousand men are available for service afloat and there are 1,000 marines besides a reserve of 20,000 men.

Justice.—Since the institution of the Ministry of Justice in

1892 very great improvements have been effected. The old tribunals, where customary law was administered by ignorant satellites of the great, amid corruption, have all been replaced by organised courts with qualified judges appointed from the Bangkok law school and under the direct control of the ministry, except in the most outlying parts. A provincial judicial scheme now in force provides a Court at the headquarters of each province (Changwat) and a Central Court at the chief town of each Circle (Monton) and a Supreme Court at Bangkok. Extra-territorial power was secured by treaty for all subjects of a foreign power. A commission for the codification of laws is in existence which is to cover Penal Code, Criminal Procedure Code, Commercial Code, Law of Judicial Organisation. When the codification has been completed the recognition of Siamese laws by all the powers may be expected and an end of extra-territoriality.

Religion.—Buddhism is the prevailing religion of the Siamese and Laos but the Malays of the Peninsula are Mohammedans. Buddhism in Siam is tinged by Burmese and Sinhalese influences and in the remote country districts by spirit-worship characteristic of the Ka and hill peoples of Indo-China. In Bangkok Brahmanical influence is still noticeable and Brahman priests assist at all acts of public importance. The Siamese, as Southern Buddhists, pride themselves on their orthodoxy and since Burma and Ceylon have ceased to be independent, the King of Siam is regarded as the sole surviving defender of the faith. A close connection exists between the laity and priesthood for the Buddhist rule prescribing that every man should enter the priesthood for at least two months is almost universally observed. The accounts given as to the profligacy and immorality in the monasteries are exaggerated. Many of the temples are under the direct supervision of the King and in these a stricter rule of life is observed. Some of the priests are learned in the Buddhist scriptures and most of the Pali scholarship in Siam is to be found in the monasteries. There is little public worship. On the day set apart for worship (*Wan Phra*, or "Day of the Lord") the attendance at the temple is small and consists mostly of women. Religious and semi-religious ceremonies play a large part in Siamese life. Few weeks pass without some function or procession. The cremations of great people, often lasting several days, are the occasion of public festivities and are celebrated with processions, theatrical shows, illuminations and fireworks. The English, French and American missionaries in Siam have done much to help on the general work of civilisation while the progress of education has been largely due to their efforts.

Education.—The Buddhist monasteries throughout the country carry on almost the whole of the elementary education in rural districts. A provincial training college was established in 1903 for the instruction of priests and laymen in the work of teaching and by this means and with regular government supervision and control the monastic schools are being brought into line with the government educational organization. The Minister of Education is responsible for education throughout the country with the exception of such Departmental schools as the Military, Naval, Law and Police schools and a few others. There are 343 Government schools with 47,268 pupils and 1,958 teachers; 65 technical departments in Government schools with 1,100 pupils, principally in training for teachers; 4,707 local schools run by the local authorities under departmental inspection, with 527,603 pupils and 9,872 teachers; 573 private schools with 27,435 pupils and 1,446 teachers. Many of the special schools use the English language for conveying instruction and in three the whole curriculum is conducted in English by English masters. In 1917 the Chulalongkorn University was founded at Bangkok. In it are incorporated special schools of Administration, Engineering, Medicine, Literature and Science. There are also Military and Naval schools. Many of the special schools award scholarships to enable the best of their pupils to complete their studies abroad.

(E. Y.)

HISTORY

The town of Lampun (Labong or Haribunchai), the first Lao capital in Siam, was founded about A.D. 575. The fusion of races may be said to have begun then, and the Siamese language, written character and other racial peculiarities were in course of formation. But the finishing touches to the new race were supplied by the great expulsion of Lao-Tai from south-west China by Kublai Khan in A.D. 1250. Thereafter the north, the west and the south-west of Siam, comprising the kingdom of Swankalok-Sukhotai, and the states of Suphan and Nakhon Sri Tammarat (Ligore), with their sub-feudatories, were reduced by the Siamese (Thai), who, during their southern progress, moved their capital from Sukhotai to Nakhon Sawan, thence to Kampeng Pet, and thence again to Suvarnabhumi near the present Kanburi. A Sukhotai inscription of about 1284 states that the dominions of King Rama Kamheng extended across the country from the Mekong to Pechaburi, and thence down the Gulf of Siam to Ligore; and the Malay annals say that the Siamese had penetrated to the extremity of the peninsula before the first Malay colony from Menangkabu founded Singapore, *i.e.*, about 1160.

Sano also was attacked, and its fall completed the ascendancy of the Siamese (Thai) throughout the country. The city of Ayuthia which rose in A.D. 1350 upon the ruins of Sano was the capital of the first true Siamese king of all Siam. This king's sway extended to Moulmein, Tavoy, Tenasserim and the whole Malacca peninsula. About this time Siam attacked Cambodia, seized Angkor and carried off some 90,000 prisoners. This was the beginning of a series of wars lasting some 400 years, until Cambodia fell entirely under Siamese rule and influence. Vigorous attacks were also made during this period on the Lao states to the north-west and north-east, and Siamese supremacy was pretty firmly established in Chiengmai and its dependencies by the end of the 18th century, and over the great eastern capitals, Luang Prabang and Vien-chang, about 1828.

Phra Naret.—During the 15th and 16th centuries Siam was frequently invaded by the Burmese and Peguans, who, attracted probably by the great wealth of Ayuthia, besieged it more than once without success, the defenders being aided by Portuguese mercenaries, till about 1555, when the city was taken and Siam reduced to dependence. From this condition, however, it was raised a few years later by the great conqueror and national hero Phra Naret, who after subduing Laos and Cambodia invaded Pegu, which was utterly overthrown in the next century by his successors. But after the civil wars of the 18th century the Burmese, having previously taken Chieng-mai, which appealed to Siam for help, entered Tenasserim and took Mergui and Tavoy in 1764, and then advancing simultaneously from the north and the west destroyed Ayuthia after a two years' siege (1767).

The intercourse between France and Siam began about 1680 under Phra Narain, who, by the advice of his minister, the Cephalonian adventurer Constantine Phaulcon, sent an embassy to Louis XIV. An interesting episode was the active intercourse, chiefly commercial, between the Siamese and Japanese governments from 1592 to 1632. Japan was, in 1636, closed to foreigners; but trade was carried on at all events down to 1745 through Dutch and Chinese and occasional English traders. In 1752 an embassy came from Ceylon, desiring to renew the ancient friendship and to discuss religious matters. After the fall of Ayuthia a great general, Phaya Takh Sin, collected the remains of the army and restored the fortunes of the kingdom, establishing his capital at Bangkok; but, becoming insane, he was put to death, and was succeeded by another successful general, Phaya Chakkri, who founded the present dynasty. Under him Tenasserim was invaded and Tavoy held for the last time by the Siamese in 1792, though in 1825, taking advantage of the Burmese difficulty with England, they bombarded some of the towns on that coast. The supremacy of China is indicated by occasional missions sent, as on the founding of a new dynasty, to Peking, to bring back a seal and a calendar.

European Contacts.—Of European nations the Portuguese first established intercourse with Siam (1511). They were supplanted gradually in the 17th century by the Dutch. English traders were in Siam very early in the 17th century; there was a friendly interchange of letters between James I. and the king of Siam, who had some Englishmen in his service, and, when the ships

visited "Sia" (which was "as great a city as London") or the queen of Patani, they were hospitably received and accorded privileges. The important items of export were, as now, tin, varnish, deerskins and "precious drugs." Later on, the East India Company's servants, jealous at the employment of Englishmen not in their service, attacked the Siamese, which led to a massacre of the English at Mergui in 1687, and the factory at Ayuthia was abandoned in 1688. A similar attack is said to have been made in 1719 by the governor of Madras. After this the trade was neglected. Pulo Penang, an island belonging to the Siamese dependency of Kedah, was granted on a permanent lease to the East India Company in 1786, and treaties were entered into by the sultan of Kedah with the company. In 1822 John Crawfurd was sent to Bangkok to negotiate a treaty with the suzerain power, but the mission was unsuccessful. In 1824, by treaty with the Dutch, British interests became paramount in the Malay Peninsula and in Siam, and, two years later, Captain Burney signed the first treaty of friendship and commerce between England and Siam. A similar treaty was effected with America in 1833. Subsequently trade with British possessions revived, and in time a more elaborate treaty with England became desirable. Sir J. Brooke opened negotiations in 1850 which came to nothing, but in 1855 Sir J. Bowring signed a new treaty whereby Siam agreed to the appointment of a British consul in Bangkok, and to the exercise by that official of full extra-territorial powers. Siam entered into treaties with Japan in 1898 and Russia in 1899. A further convention afterwards provided for a second British consular district in northern Siam, while England and France have both appointed vice-consuls in different parts of the country.

France and England.—For centuries Siam had been distracted by wars with Cambodians, Peguans and Burmans, but the incorporation of Lower Cochin China, Annam and Tongking by the French, and the annexation of Lower and Upper Burma successively by the British, freed her from all further danger on the part of her old rivals. But later, disputes with frontier tribes led to complications with France, who asserted that the Siamese were occupying territory that rightfully belonged to Annam, which was now under French protection. France, while assuring the British Government that she laid no claim to the province of Luang Prabang, which was situated on both banks of the upper Mekong, roughly between the 18th and 20th parallels, claimed that farther south the Mekong formed the true boundary between Siam and Annam, and demanded the evacuation of certain Siamese posts east of the river. The Siamese refused to yield, and early in 1893 encounters took place in the disputed area, in which a French officer was captured and French soldiers were killed. The French then despatched gunboats from Saigon to enforce their demands at Bangkok, and these made their way up to the capital in spite of an attempt on the part of the Siamese naval forces to bar their way. In consequence of the resistance with which they had met, the French now greatly increased their demands, insisting on the Siamese giving up all territory east of the Mekong, including about half of Luang Prabang, on the payment of an indemnity and on the permanent withdrawal of all troops and police to a distance of 25 kilometres from the right bank of the Mekong. Ten days' blockade of the port caused the Siamese government to accede to these demands, and a treaty was made, the French sending troops to occupy Chantabun until the provisions of this treaty should have been carried out.

In 1895 lengthy negotiations took place between France and England concerning their respective eastern and western frontiers in Farther India. These negotiations bore important fruit in the Anglo-French convention of 1896. By this convention Siam's independence was guaranteed by the two European powers who alone have interests in Indo-China. Encouraged by the assurance of the Anglo-French convention, Siam now turned her whole attention to internal reform, and to such good purpose that, in a few years, improved government and expansion of trade aroused a general interest in her welfare, and gave her a stability which had before been lacking. With the growth of confidence negotiations with France were reopened, and, after long discussion, the treaty of 1893 was set aside and Chantabun evacuated in return for the cession of the provinces of Bassac, Melupré, and the remainder of Luang Prabang, all on the right bank of the Mekong, and of the maritime district of Krat. These results were embodied in a new treaty signed and ratified in 1904.

Meanwhile, in 1899, negotiations with the British government led to agreements defining the status of British subjects in Siam, and fixing the frontier between southern Siam and the British Malay States, while in 1900 the provisions of Sir J. Bowring's treaty of 1855, fixing the rates of land revenue, were abrogated in order to facilitate Siamese financial reform.

In 1907 a further convention was made with France, Siam returning to the French protectorate of Cambodia the province of Battambang conquered in 1811, and in compensation receiving back from France the maritime province of Krat and the district of Dansai, which had been ceded in 1904. This convention also modified the extra-territorial rights enjoyed by France in Siam, and disclosed an inclination to recognize the material improvements of the preceding years. In 1907 also negotiations were opened with Great Britain, the objects of which were to modify the extra-territorial rights conceded to that power by the treaty of 1855, and to remove various restrictions regarding taxation and general administration, which, though diminished from time to time by agreement, still continued to hamper the government. These negotiations resulted in a treaty, signed and ratified in 1909, by which Siam ceded to Great Britain her suzerain rights over the dependencies of Kedah, Kelantan, Trengganu and Perlis, Malay states situated in southern Siam just north of British Malaya, containing in all about a million inhabitants and for the most part flourishing and wealthy, and obtained the practical abolition of British jurisdiction in Siam proper.

In 1917 Siam declared war on Germany and Austria-Hungary. All enemy subjects were interned and a quantity of German shipping taken as prize. The most important modern treaties are those made with the United States (1920); Japan (1924); Denmark, France, Holland, Portugal and Spain (1925); and in the same year a provisional economic arrangement was entered into with Germany. In 1925, also, two new treaties (a new general and a new commercial treaty), were signed between Great Britain and Siam: they were ratified in May 1926. The present king is Prajadhipok of Sukhodaya, born Nov. 8, 1893. He succeeded his brother Rama VI. in Nov. 1925 and he is the seventh monarch of the present reigning dynasty.

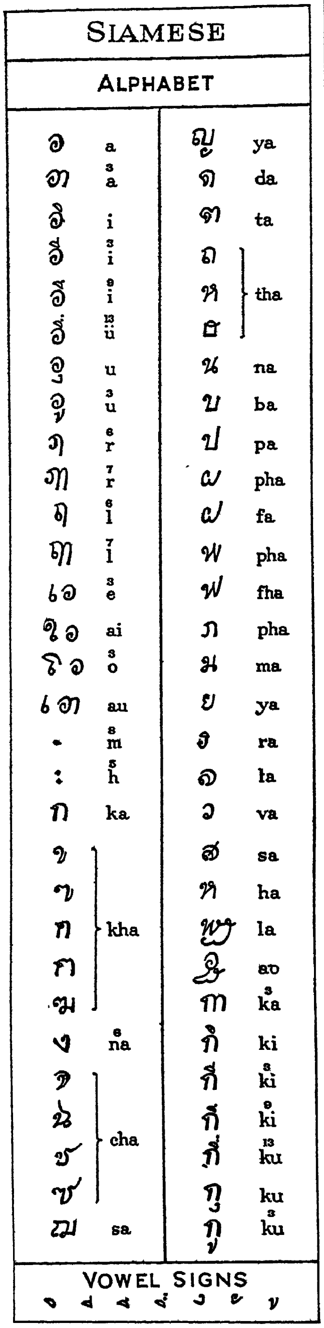
SIAMESE LANGUAGE AND LITERATURE. Siamese belongs to the Tai group of the Siamese-Chinese family of languages. Its connection with Chinese is distant but with other languages of the Tai group very close. It is spoken throughout central Siam, in all of southern Siam except Patani Monton, in northern Siam along the river-banks as far up as Utaradit and Raheng, and in eastern Siam as far as the Korat Monton. Siamese was purely monosyllabic, each true word consisting of a single vowel sound preceded by, or followed by, a consonant. Of such monosyllables there are less than 2,000, and therefore many syllables have to do duty for the expression of more than one idea, confusion being avoided by the tone in which they are spoken.



The current Siamese characters are derived from the Cambodian alphabet, which owes its origin to the alphabet of the inscriptions, an offshoot of the character found on the stone monuments of southern India in the 6th and 8th centuries.

The Siamese alphabet consists of 44 consonants, in each of which the vowel sound "aw" is inherent, and of 32 vowels all marked not by individual letters, but by signs written above, below, before, or after the consonant in connection with which they are to be pronounced. Several of the 44 consonants express each a slightly different intonation of what is practically the same consonant, the sound of "kh," for instance, being represented by six different letters and the sound of "t" by eight. Other letters are present only for use in certain words imported from Pali. The vowel signs have no sound by themselves, but act upon the vowel sound "aw" inherent in the consonants, converting it into "a," "i," "o," "ee," "ow," etc. Each of the signs has a name, and some of them produce modulations so closely resembling those made by another that at the present day they are scarcely to be distinguished apart. Only vowel or diphthong sounds, or the letters "m," "n," "ng," "k," "t," and "p" are permissible at the end of words. Hence the final letter of all words ending in anything else is simply suppressed or is pronounced as though it were a letter naturally producing one or other of those sounds. Thus many of the words procured from foreign sources are more or less mutilated in pronunciation, though the entirely suppressed or altered letter is still retained in writing.

Siamese is written from left to right. In manuscript there is usually no space between words, but punctuation is expressed by intervals isolating phrases and sentences.

The Tonal System.—Of the simple tones there are five—the even, the circumflex, the descending, the grave, and the high—any one of which when applied to a word may give it a quite distinct meaning. Four of the simple tones are marked in the written character by signs placed over the consonant affected, and the absence of a mark implies that the one remaining tone is to be used. The consonants are grouped into three classes, to each of which a special tone applies, and consequently the application of a tonal sign to a letter has a different effect, according to the class to which such letter belongs. Though many syllables have to do duty for the expression of more than one idea, the majority have only one or at most two meanings, but some are used with quite a number of different inflections, each of which gives the word a new meaning. Thus, for example, the syllable *khao* may mean "they," "badly," "rice," "white," "old," or "news," simply according to the tone in which the word is spoken. Words are unchangeable and incapable of inflection. There is no article, and no distinction of gender, number, or case. These, when necessary, are expressed by explanatory words after the respective nouns; only the dative and ablative are denoted by subsidiary words, which precede the nouns, the nominative being marked by its position before, the objective by its position after, the verb, and the genitive (and also the adjective) by its place after the noun it qualifies. Occasionally, however, auxiliary nouns serve that purpose. Words like "mother," "son," "water" are often employed in forming compounds to express ideas for which the Siamese have no single words, *e.g. lûk cân,* "the son of hire," a labourer; *mê mü,* "the mother of the hand," the thumb. The use of class words with numerals obtains also. In Siamese the personal pronouns are mostly represented by nouns expressive of the various shades of superior or lower rank according to etiquette. The verb is, like the noun, perfectly colourless—person, number, tense, and mood being indicated by auxiliary words only when they cannot be inferred from the context. Such auxiliary words are *yû,* "to be," "to dwell," (present); *dai,* "to have"; *leao,* "end" (past); *cā,* "also" (future); the first and third follow, the second and fourth precede, the verb. *Hài,* "to give" (prefixed), often indicates the subjunctive. There are compound verbs; thus, *e.g., pai,* "to go," is joined to a transitive verb to convert it into an intransitive or neuter; and *thûk,* "to touch," and *tòng* "to be compelled," serve to form a sort of passive voice. The number of adverbs, single and compound, is very large. The prepositions mostly consist of nouns.

In Siamese the subject of the sentence precedes the verb and the object follows it. The possessive pronoun follows the object. The adverb usually follows the verb. In compound sentences the verbs are placed together as in English, not separated by the object as in German. When an action is expressed in the past the word which forms, with the verb, the past tense is divided from the verb itself by the object.

In addition to the ordinary language of the people there is a completely different set of words ordained for the use of royalty, to avoid the employment of downright expressions of vulgarity or of words which might be capable of conveying an unpleasant or indelicate idea other than the meaning intended. Words of Sanskrit origin have been freely adopted and many Cambodian words are also used. The language is so complete that the dog, pig, crow, and other common or unclean animals are all expressed by special words, while the actions of royalty, such as eating, sleeping, walking, speaking, bathing, dying, are spoken of in words quite distinct from those used to describe similar actions of ordinary people.

See O. Frankfurter, *Elements of Siamese Grammar* (1900); *Linguistic Survey of India,* vol. ii. (1904).

LITERATURE

The genius of the Siamese finds its best literary expression in verse which contains a great variety of metre, but the three commonest metres are called *Klon, Kap* and *Klong.* The tones of the language play a very important part in Siamese poetry—indeed they may be said to take the place of rhymes; the *Kap,* however, has rhymes in addition. Every subject is material for the Siamese poet and the verses are comparable with those of almost any land. *Klong* and *Kap* forms are combined in the style known as *Nirat* poetry, or extended narrative love-verse, and the *Klon'pet ton* or thumb-nail love-songs are numbered by hundreds. They are unrivalled for elegance of diction and sweet sound, perfectly balanced little pieces of eight lines divided into two stanzas; each line having eight syllables. This form of verse

is confined to the treatment of love and passion. The other metres are of interest only to the academician.

Siamese is rich in quasi-historical and mythological literature. The purely native material is informed by an imagination far less vivid than that of the Indian *Ramayana*, (*Ramakien*), but is decidedly interesting as an index of the Siamese mind. It is sometimes very difficult to decide whether a story is purely native, as Siam drew upon the mighty sources of India, Cambodia and China; where the material was not too definitely alien, the Siamese pressed it very closely into their own mould, producing a very different piece of literary effort from the original. *Wet ya Sun yin* and *Wo ra loongs* are examples of stories originally borrowed from India. Semi-magical stories are numerous and nature-stories abound. A study of the mythological literature sheds a flood of light on the origin and development of Indo-Chinese superstition. *Phum hon,* a very popular tale, tells of a young woman loved by an elephant, and *Prang tong* is a story of a princess who was prenatally betrothed to a giant. Siamese cosmogony is enshrined in the *Nok khum,* and these mythological works may be considered the earliest examples of native literature.

There exists much religious material in Siamese—almost the whole of the Buddhist Canon having appeared, some parts of it existing in many different versions: *Pattama Sompothiyan* is the standard Siamese life of Buddha. There is often great difficulty in distinguishing between Buddhist literature proper and *Niti* or traditional literature. Much of this is from the Bali language and from Javanese, which in their turn were inspired from India. The outstanding work in this division is called the *Maxims of Phra Ruang*. Phra Ruang was the national hero-king and he is held up to Siamese youth as the mighty ideal of manhood.

It is in law that Siamese literature shows its best early prose. Five ancient canons, some of them founded on the *Law of Manu,* exist and present the earliest form of Siamese law and a very early style of Siamese literary composition. A large collection of early royal edicts has come down to our day although a modern code of laws has long since superseded the old statutes. A penal code based on foreign procedures was issued in 1908 and additions are made periodically. Never has Siam published so lavishly; every month new legal codes, translations of religious texts, new versions of foreign classics or translations of alien literature roll from unwearied presses. More especially versions from the Pali scriptures of Buddhism abound and there is nowadays a movement on foot to supply the lacunae in historical literature.

The wars of the middle ages and early modern times in Siam have robbed us of much literary material which must have existed centuries ago. There is as yet no reliable, connected history of Siam in the native tongue, although we have a fairly complete history of the Aguthia dynasty and of the modern line of kings. The cause for dissatisfaction with these histories is almost entirely concerned with the earlier parts which have drawn largely upon the quasi-historical and legendary literature. Modern works on general history are of almost daily publication now, however, and histories of Siam, based on material drawn from foreign contemporary sources are in course of preparation. The educational department of the Siamese Government is indeed the modern fairy godmother of the people in matters of dissemination of general knowledge. (See *Catalogue of the India Office Library,* London.)

(A. N. J. W.)

SI-AN (Hsi Gnan Fu; Si Gnan Fu; Si-gan Fu; Sian Fu), the capital of the province of Shensi, in north-west China, in 34° 17′ N., 108° 58′ E. The city is said to have one million inhabitants, of whom 50,000 are Mohammedans. The site is on a broad loess terrace the surface of which is of recent accumulation. Si-an lies where the road over the Tsin-ling shan meets the road down the Wei valley. Eastward of Si-an the valley narrows remarkably to the fortress of Tung-kwan. The city is in a fertile spot commanding routes up and down the Wei-ho, to Kansu and Central Asia, as well as to Szechwan and Tibet. Its strategical position at the entry into China from the west has helped it to play an important part in the history and administration of China. Shi Hwang-ti (246–210 B.C.), the first universal emperor, established his capital at Kwan-chung, on the site of the modern Si-an. Under the succeeding Han dynasty (206 B.C.–A.D. 14), this city was called Wei-nan and Nui-shi; under the eastern Han (A.D. 25–221) it was known as Yung Chow; under the T'ang (618–907) as Kwannui; under the Sung (960–1127) as Yung-hing; under the Yuan and Ming (1260–1644) as Gan-si. During the Ts'in, Han and T'ang dynasties the city was usually the capital of the empire, and in size, population and wealth it is still among the most important cities of China. It was visited by Marco Polo in the 13th century, and he refers to it as Kenjanfu. During the Mohammedan rebellion it was unsuccessfully besieged by the rebels during 1868–70. The city is square in plan, and includes within its limits the two district-cities of Ch'ang-gan and Hei-ning. There are extensive walls and fortifications around the city. Several of the temples and public buildings are very fine, and many historical monuments are found within and about the walls. Many of these are now housed in the Pei Lin, or "forest of tablets," a museum containing tablets, coins, bronzes, etc., appertaining to the history of the city. One of the most notable is the Nestorian tablet, accidentally discovered in 1625 in the Ch'ang-gan suburb. The stone slab is 9 ft. high by 3 ft. wide.

The contents of the inscription, which consists of 1,780 characters, may be described as follows: (1) An abstract of Christian doctrine of a vague and figurative kind. (2) An account of the arrival of the missionary, Olopan (probably a Chinese form of Rabban=Monk) from Tats'in in the year 635, bringing sacred books and images; of the translation of the said books; of the imperial approval of the doctrine and permission to teach it publicly. Then follows a decree of the emperor (T'ai-tsung, a very famous prince), issued in 638, in favour of the new doctrine, and ordering a church to be built in the square of justice and peace (*Ining fang*) in the capital. The emperor's portrait was to be placed in this church. After this comes a description of Tats'in, and then some account of the fortunes of the church in China. Kaotsung (650–683, the devout patron also of the Buddhist traveller and doctor, Hsüan Ts'ang) it is added, continued to favour the new faith. In the end of the century Buddhism got the upper hand, but under Yuen-tsung (713–755) the church recovered its prestige, and Kiho, a new missionary, arrived. Under Tih-Tsung (780–783) the monument was erected, and this part of the inscription ends with a eulogy of I-sze, a statesman and benefactor of the church. (3) Then follows a recapitulation of the above in octosyllabic verse. The Chinese inscription, which concludes with the date of erection, viz., 781, is followed by a series of short inscriptions in Syriac, and the *Estrangelo* character, containing the date of the erection, the name of the reigning Nestorian patriarch, Mar Hanan Ishua, that of Adam, bishop and pope of China, and those of the clerical staff of the capital. Then follow 67 names of persons in Syriac characters, most of whom are characterized as priests, and 61 names of persons in Chinese, all priests but one.

The stone remained in the enclosure of a dilapidated temple until 1907, when it was housed in the Pei Lin and a replica deposited, in 1908, in the Metropolitan Museum of Art, New York, moved later to the Lateran, in Rome, under pontifical charge. Replicas have been given by Prince Frits Holm to 14 countries.

The importance of Si-an as a trade centre was noticed by Marco Polo, who mentions it as a place "of great trade and industry. They have great abundance of silk, from which they weave cloths of silk, and gold of divers kinds, and they also manufacture all sorts of equipments for an army. They have every necessary of man's life very cheap." The trade, before the recent period of disorder, was also extensive. To the northward were sent cotton, tea, tobacco and cereals, and from the north, coal, iron and salt were imported. To Kansu were sent cotton and cereals, while horses, wool, sheep, fur and tobacco were imported. Silk and tea, porcelain, sugar and paper were sent to Kuku Nor and thence to Central Asia, while from the west Si-an received rhubarb and medicinal herbs, the products of stock breeding, jade from the Tarim basin (Khotan), and a quantity of cloth from Russia. Cotton, wool, skins and fur were sent to Szechwan, while sugar, silk and cheap opium were imported. Medicinal plants were received from South China. From the south-east, through

Hang-chow, came tea, paper, porcelain, pepper and European materials, while most of the silk also came this way.

SIBELIUS, JOHAN JULIUS (1865–), Finnish composer, known as Jean Sibelius, was born at Tavastehus on Dec. 8, 1865. He studied music under Wegelius at Helsingfors 1885–89, under Becker 1889–90 in Berlin, and under Fuchs and Goldmark in Vienna 1890–91. He showed imagination and power of expression, a masculine sentiment and a respect for his art which never allowed him to abuse his profound technical powers for the display of mere virtuosity. Among his compositions are: 10 symphonic poems, six symphonies, a violin concerto, a string quartet, *Voces Intimae, Valse Triste,* several works for choir and orchestra, incidental music to *Pelléas et Mélisande, As You Like It, The Tempest,* the pantomime, *Scaramouche,* numerous songs and miscellaneous pieces.

ŠIBENIK, a port of Dalmatia, Yugoslavia, on the Adriatic Sea (Ital. *Sebenico*). Pop. (1910) 12,588, over 98% being Croatians. Šibenik, full of Venetian Gothic and Renaissance architecture, is built on a steep hill, and is partly walled. On the seaward side are two forts, now dismantled, and the castle of St. Anna. There are both Orthodox and Roman Catholic bishops, the see of the latter having been founded in 1298. Most of the inhabitants are of the Roman faith and have a beautiful cruciform church built entirely of stone, even the waggon vaults over the nave, choir and transepts being unprotected by lead or tiles. Probably no other church in Europe, of equal size, is similarly constructed. The older part (1430–41) is Italian Gothic.

Šibenik is a naval base, has a wireless station and a steamship station, and has a considerable export trade in bauxite. It is lighted by electricity, the power being supplied by the celebrated falls of Kerka. There are several schools including a secondary one, and also a Forest School. The town is a weaving centre, and here the national costumes are made. Other industries include an insecticide powder mill, a calcium carbide factory, woollen mills, oil refining, the preparation of the *Rhus Cotenus* for dyeing purposes, wine and honey, while fishing and sponge and coral fishing are also carried on. Many of the inhabitants are fishermen.

Šibenik is said to have been founded by the Uskoks (*see* Bosnia) fleeing from Turkish oppression, who then took to piracy. Later the town became famous as a favourite residence of the Croatian kings. In 1117 it was captured by Venice, but held by Hungary from 1351 to 1412, when it again became Venetian. In 1647 it was unsuccessfully besieged by the Turks, and after the fall of Venice in 1797 it became French. From 1815 to 1918 it was Austrian, and in the latter year, before Dalmatia was incorporated in Yugoslavia, it was occupied by the Italians.

SIBERIA, the name in Russian Sibir, of the chief settlement of the Tatar khan Kuchum, Isker on the Irtysh, which was captured by the Cossack *Yermak* in 1581. Subsequently the term was used to denote the dominions of Russia in northern Asia, which were the first to be absorbed by Russia, the more densely peopled south retaining its independence longer. The term had considerable elasticity as regards its southern boundary, being used sometimes as if it included the steppes of the south and at other times as if the steppes of Akmolinsk, Semipalatinsk and the Turgai were not included. Administratively it is now divided into the Uralsk Area, which also includes part of European Russia, the Siberian Area, the Yakutsk Republic, The Buriat Mongol Republic and the Far Eastern Area, while the steppe region above referred to is incorporated in the Kazak republic (*qq.v.*). The geography of Siberia is included in the article Russia (*q.v.*). (X.)

History.—According to Radlov, the earliest inhabitants were the Yeniseians who were followed by the Ugro-Samoyedes, who also came originally from the high plateau and were compelled, in the 3rd century B.C., to cross the Altai and Sayan ranges and to enter Siberia. To them must be assigned the remains dating from the Bronze period which are scattered all over southern Siberia. Iron was unknown to them; but they excelled in bronze, silver and gold work. Their ornaments and implements, often polished, evince artistic taste; and their irrigated fields covered wide areas. On the whole, their civilization stood much higher than that of their more recent successors. Eight centuries later the Turkish stocks of "Tukiu" (the Chinese spelling for "Turks"), Khagases and Uigurs—also compelled to migrate north-westwards from their former seats—subdued the Ugro-Samoyed. They likewise left numerous traces of their sojourn, and two different periods may be distinguished in their remains. They were acquainted with iron, and learned from their subjects the art of bronze-casting, which they used for decorative purposes only, and to which they gave a still higher artistic stamp. Their pottery is much more perfect and more artistic than that of the Bronze period, and their ornaments are accounted among the finest of the collections at the St. Petersburg museum of the Hermitage. This Turkish empire of the Khagases must have lasted until the 13th century, when the Mongols destroyed their civilization. A decline is shown by the graves which have been discovered. In the beginning of the 16th century Tatar fugitives from Turkestan subdued the loosely associated tribes inhabiting the lowlands to the east of the Urals. Agriculturists, tanners, merchants and mollahs (priests) were called from Turkestan, and small principalities sprang up on the Irtysh and the Ob. These were united by Khan Ediger, and conflicts with the Russians, who were then colonizing the Urals, brought him into collision with Moscow; his envoys came to Moscow in 1555 and consented to a yearly tribute of 1,000 sables. As early as the 11th century, the Novgorodians had occasionally penetrated into Siberia; but the fall of the republic checked the advance of the Russians. On the defeat of the rebel Stenka Razin (1667–71) many who were unwilling to submit to the iron rule of Moscow made their way to the settlements of Stroganov in Perm, and tradition has it that, in order to get rid of his guests, Stroganov suggested to their chief, Yermak, that he should cross the Urals into Siberia, promising to help him with supplies of food and arms. Yermak entered Siberia in 1580 with a band of 1,636 men, following the Tagil and Tura rivers. Next year they were on the Tobol, and 500 men successfully laid siege to Isker, the residence of Khan Kuchum, in the neighbourhood of what is now Tobolsk. Kuchum fled to the steppes, abandoning his domains to Yermak, who, according to tradition, purchased, by the present of Siberia to Ivan IV., his own restoration to favour. Yermak was drowned in the Irtysh in 1584 and the Cossacks abandoned Siberia. But new bands of hunters and adventurers poured every year into the country, and were supported by Moscow. To avoid conflicts with the denser populations of the south, they preferred to advance eastwards along higher latitudes; meanwhile Moscow erected forts and settled labourers around them to supply the garrisons with food. Within 80 years the Russians had reached the Amur and the Pacific. This rapid conquest is accounted for by the circumstance that neither Tatars nor Turks were able to offer any serious resistance. In 1607–10 the Tunguses fought for their independence, but were subdued about 1623. In 1628 the Russians reached the Lena, founded the fort of Yakutsk in 1637, and two years later reached the Sea of Okhotsk at the mouth of the Ulya river. The Buriats offered some opposition till, in 1643 Poyarkov's boats descended the Amur, returning to Yakutsk by the Sea of Okhotsk and the Aldan, and in 1649–50 Khabarov occupied the banks of the Amur. In 1852 a Russian military expedition under Muraviev explored the Amur, and by 1857, a chain of Russian Cossacks and peasants were settled along the whole course of the river. The accomplished fact was recognized by China in 1857, and 1860 by a treaty. In the same year in which Khabarov explored the Amur (1648) the Cossack Dejnev, starting from the Kolyma, sailed round the north-eastern extremity of Asia through the strait which was rediscovered and described 80 years later by Bering (1728). Cook in 1778, and after him La Pérouse, settled definitively the broad features of the northern Pacific coast. Although the Arctic ocean had been reached as early as the first half of the 17th century, exploration of its coasts was begun only in the 18th century (1735–39).

The scientific explorations of Siberia, begun in the period 1733 to 1742 by Messerschmidt, Gmelin, and De Lisle de la Croyère, was followed up by Müller, Fischer and Georgi. Pallas, Hansteen and Erman (1828–30), Humboldt, Ehrenberg and Gustav Rose also paid in the course of these years short visits to Siberia. Ritter elaborated in his *Asien* (1832–59), the foundations of a sound knowledge of the structure of Siberia. To Middendorff's journey (1844–45) to north-eastern Siberia—contemporaneous with Castrén's journeys for the special study of the Ural-Altaian languages—the expeditions of Akhte and Schwarz (1852), and later on (1854–57) of the Siberian expedition we owe so marked an advance in our knowledge of East Siberia. The Siberian branch of the Russian Geographical Society was founded at the same time at Irkutsk, and afterwards became a permanent centre for the exploration of Siberia; while the opening of the Amur and Sakhalin attracted Maack, Schmidt, Glehn, Radde and Schrenck, whose works on the flora, fauna and inhabitants of Siberia have become widely known.

Political History.—The events along the trans-Siberian track after the abdication of the tsar in March 1917, his murder in 1918, and the fall of the Provisional Government (Nov. 1917) were part of the general history of the time. Siberia had supplied the moderate Socialists with a valuable contingent of soldiery taken from the political exiles, and also, regrettably, many criminals. Conditions in Siberia were determined by the retreat thither of anti-Bolshevik politicians and the presence of English, French, Japanese and American armed forces, while Russia was in the hands of Lenin, who had made a separate peace with Germany. Czecho-Slovak troops, 70,000 in number, who were opposed to the Brest-Litovsk Treaty, had no other way of exit from Russia. They held and defended the Siberian line until they had to give it up. Siberia, loosely organized, became a centre of resistance to Bolshevik rule under Admiral Kolchak, who took the title of supreme ruler. He was defeated by the Red armies after an attempted invasion of European Russia, and perished in the debacle. (*See* RUSSIA: *History*.)

Since 1920 the gradual organization of the Siberian section within the so-called federal framework of the Union of Socialist Soviet Republics has led to the establishment, under the name of republics (1922–23), of various administrative units. The major part of Siberia (pop. 8,238,000, area 4,500,000 sq. kilo.), forms a region within the U.S.S.R.; the Buriats (481,100) and the Yakuts (288,200) form republics and with the Far Eastern republic (1,721,900), are parts of the U.S.S.R.

SIBERIAN AREA, an administrative unit of Asiatic Russia, with an area of 4,028,615 square kilometers. The Arctic ocean, from Gyda bay to Khatanga bay forms its northern, and Mongolia and the Kazakstan A.S.S.R. its southern boundary. To the west lies the Uralsk Area, and to the east the Yakutsk and Buriat-Mongol republics. It coincides roughly with the former Yeniseisk, Tomsk and Irkutsk Governments of Imperial Russia. The name Siberia (Sibir) was the Russian name given to the chief settlement, Isker on the Irtysh, of the Tatar Khan Kuchum, and was subsequently extended to include the whole of the Russian dominions in Asia. After the 1917 revolution various republics and areas, each having a good deal of local autonomy were separated off and now the name Siberia is limited to the central region which was not thus split off. Much of it consists of the basin of the Yenisei river (*q.v.*). Stretching from the Sayan alpine regions in the south (lat. 51° 45′ N.) to Cape Chelyuskin in the north (77° 38′ N.), it displays much orographical variety. The West Sayan mountains have their southern base on the plateau, and their northern at a much lower level, and reach heights of 10,000 feet. Around and north-east of Lake Baikal well-marked ridges fringe the plateau, with steep north-western slopes turned towards the valleys (*e.g.*, the beautiful and fertile valley of the Irkut river between the Tunka Alps and the Sayan). A typical feature of the north-eastern border of the high plateau is a succession of broad valleys, longitudinal in an orographical sense, but not geologically, since they are erosion valleys and not synclinal foldings of rocks. Formerly submerged by Alpine lakes, they are now sheeted by flat alluvial soil, suitable for agriculture, and drained by rivers which afterwards make their way northwards through narrow gorges pierced in the mountain walls; the valleys of the Us, the Upper Oka and Irkut are of this type.

An Alpine region, 100 to 150 m. in breadth, fringes the plateau to the north-west, and is called in east Siberia the *taiga:* it consists of separate chains of mountains (4,800 to 6,500 ft.) clothed with dense forest, except on the highest parts, and having narrow marshy valleys, thickly strewn with boulders, *e.g.*, the Altai in the west, the Kuznetskiy Ala-tau, the Us and Oya mountains in West Sayan, the Nizhne-Udinsk taiga, and several chains pierced by the Oka river. North of these alpine regions is the broad belt of fertile black-earth high plains (1,200 to 1,700 ft.) stretching from Tomsk eastwards, and from Kansk penetrating in a great arc south-eastwards to Irkutsk (*see* YENISEI RIVER for structure). North of the town of Yeniseisk, and east of the Yenisei river is a broad belt of Alpine tracts of Archaean origin reaching their greatest elevation in the Yeniseisk taiga, between the Angara (Upper Tunguska) and the Middle or Stony Tunguska. North of this region begins the slope towards the Arctic plains, interrupted by the north-west to south-east ranges of the Upper Inbatsk district and the Syverma, beyond which lie the bleak tundra plains.

The Taimyr peninsula is strictly the name of the northward projection from Taimyr bay on the west to Khatanga gulf on the east, but it is often applied to the whole district between the Yenisei gulf and the Khatanga gulf. The northern coast and the islands off it are not yet accurately known: the Russian explorer Vilkitski, in 1913–14, discovered the islands named after him, lying south of the Nordenskjöld archipelago. Recent corrections of the coast of western Siberia resulting from the explorations of Russian navigators indicate that, except for Cape Chelyuskin, the Taimyr peninsula stretches about 40 m. farther north, and that the gulfs of the Ob and Yenisei should be farther to the west than shown on older maps. East of Cape Chelyuskin good harbours are scarce, but the *Eclipse* in 1914–15 wintered safely in a bay in long. 92° E., and Vilkitski's *Taimyr* in that winter remained safely frozen in Toll bay in lat. 76° 30′ N., long. 100° E. A rolling treeless tundra plain (100 to 150 ft.) covers Taimyr except for the Byrranga mountains (2,000 to 3,000 ft.) and, though comparatively well drained, is difficult to cross except in winter: erratic blocks are widely distributed. Polar bears and seals are found in summer, and in that season Samoyede reindeer breeders migrate to Taimyr Land with their herds, avoiding the Taimyr gulf region,

which is deficient in reindeer "moss." In winter the region is deserted.

Ethnology.—The majority of the population in the Siberian Area is Russian, but there are still survivals of earlier immigrants. Of the Palaeo-Siberians, the most interesting are the Yenisei Ostyaks living along the Yenisei and its tributaries from Yeniseisk to the Lower Tunguska, and most numerous about Sumarokovo, near the confluence of the Stony Tunguska. They are probably a remnant of the primitive aborigines of Siberia, and their race and language are unrelated to any other. They are in no way connected with the Ostyaks of the Ob basin, and are not Mongolian in appearance. They are fairer than the other Yenisei races and sometimes have long, oval faces and fine hair. They call themselves Tindigyet, Kanacket or Din (people), and live in birch bark tents and use hollowed trees for boats. They are a hunting and fishing people and apparently came from the Tom basin, where some place names belong to their language.

Of the Neo-Siberians, the Samoyedes are the most widespread. They have migrated from the Altai, driven north by the Turco-Tatars in the 5th century A.D., and may be the descendants of the people whose civilization can be traced in the Upper Yenisei. They are closely related to the Finno-Ugrians and Samoyede may be a corruption of *Suomi*, the name the Finns give to their native land. The three chief branches in the Siberian Area are the Tavgi reindeer nomads of the Taimyr region, the hunting Ostyak Samoyedes between the taiga and the tundra, and the fishing and hunting Samoyedes along the banks of the Yenisei. They are meso- to brachycephalic, have straight black hair, sallow skin, narrow oblique eyes and broad flat faces and noses. They are short, stout and muscular. Related to them are the Beltirs of the Abakansk steppe, the Kaibals of the Upper Yenisei, the Kamassins of Kainsk, the Karagasses, Motors, and Soyots of the Sayan district. These southern peoples are being absorbed; they frequently speak Tatar and have become settled cultivators or herdsmen. Of the Tatars, the chief branches are those of the Baraba steppe and the Chulim river, who are gradually becoming Russianized, the Altai Tatars, including the Teleuts or Telengites of the Kuznetsk district, the Chern or Black Forest Tatars of the Biya river, and the Tatars of the Abakansk steppe. The Tatars of the Altai mountains are successful cattle and horse breeders, and have large flocks of sheep and goats. There are some Tungusic tribes between the Lower and Middle Tunguska, the best known being the Chapogir. Their original home was Manchuria and they are of the Ural-Altaic group to which the Manchus belong, and are nomad reindeer breeders. The Russian population is mainly settled in the rich agricultural belt through which the trans-Siberian railway passes.

Agriculture and Stock Raising.—Cultivation is densest round Omsk, especially to the south, and in the region to the south of the railway from Lake Chany eastwards to Tomsk. Eastward from that region there are scattered patches along the railway, and along the courses of the Upper Yenisei and its tributaries, especially in the Abakan and Tuba valleys. From Irkutsk a belt of cultivation extends along the Angara and its tributaries as far north as lat. 55° N. The chief crops are wheat, rye, barley, potatoes, flax, hemp, sunflower seed, beans and grasses. In the Minusinsk district beet is successfully grown and there are beet sugar factories; water melons also thrive. In Irkutsk rye is the predominant crop. The sandy black soils of the Kainsk and Mariinsk districts near Tomsk, and of the Altai favour wheat production, as does the black earth of the Baraba steppe, and wheat in these districts forms 50 to 75% of the harvest. The brown, less fertile soils of Tomsk are favourable to barley and spring rye. Winter rye and oats flourish east of Tomsk. The long winter and slight snowfall everywhere make spring corn a better crop than winter corn, and fruit growing is rarely successful. Makhorka tobacco is grown along the Irtysh, south of Omsk, and supplies the Omsk tobacco factory.

Of wild produce, the cones of the *Pinus Cembra* of the northern Tomsk and Mariinsk districts and of the mountain regions of Biisk and Kuznetsk find a ready market in the oil pressing factories of Tomsk; bilberries, cranberries and dried mushrooms are also exported. The introduction of agricultural machinery and of fertilizers is improving the harvest. Novo-Sibirsk and Omsk are the chief centres of distribution, and there is a machine-testing station at Novo-Sibirsk. Grain elevators are increasingly common. Most grain is exported unmilled, but Tomsk, Biisk, Barnaul and Novo-Sibirsk have extensive milling industries. Freightage costs militate against the export of Siberian grain. Dairying is the most productive occupation, though only introduced in 1893. There are technical dairy schools at Omsk, Kainsk, Barnaul and Zmyeinogorsk, in addition to a central laboratory at Tomsk and other small local laboratories. The reasons for its success are its small bulk which lessens transport difficulty, and the fact that Siberian milk contains a high proportion of fat owing to the rich pasture; the average yield is 1 lb. of butter to 20·05 lb. milk as against 1 lb. to 28 lb. in Denmark. Ice trucks for butter leave Novo-Sibirsk several times a week during the summer and collect from the various butter transit centres en route. Siberian cheese is increasingly finding its way on to the market. East of Krasnoyarsk dairy farming is of little importance; the cattle are few in number, small, and yield little milk.

Horses and working cattle are raised, especially in the west, for local use; the Kuznetsk breed is famous, but the number of horses fell during the post-1914 period and have not yet reached pre-war numbers. The stock raising districts of Minusinsk, Achinsk and Turukhansk are recovering more rapidly. Sheep-breeding, especially of the newly introduced merino sheep, is rapidly developing on the Yenisei plains, where the hay is excellent. Pig-breeding has developed with the increasing dairy industry, which provides buttermilk as pig food, and bacon and sausage factories are springing up. Reindeer are valuable in the Turukhansk district, while in the southern hill regions the *maral*, a kind of wapiti, is bred in farms for the sake of its horns, which are in demand in China for the preparation of a drug called *panty*. Bee-keeping is of very ancient origin, and is profitable in the Achinsk, Minusinsk, Kusnetsk, Biisk and Zmyeinogorsk districts; the destruction of the forests and the desiccation of the steppe have diminished it elsewhere. In spite of the vast forest wealth of the region the timber industry is little developed, mainly owing to the lack of transport facilities; the Tomsk district is markedly deficient in timber and receives some of its timber from camel transport across the Kirghiz steppe. If the Yenisei sea-route comes into regular use, a timber export may spring up on that river. There are timber mills at Omsk, Novo-Sibirsk and Tomsk; those at Novo-Sibirsk use the wood from the district between Barnaul and the railway, but these mills supply local needs only, as do the mills at Irkutsk.

Mining.—The mineral wealth of the region is great, but little worked at present. Rich deposits of magnetic iron ore exist on the Telbes, a tributary of the Kondoma near Kuznetsk, with beds of good coking coal 20 m. away. Gold exists in quantity, but is hampered by lack of proper dredging apparatus. The Mariinsk taiga gold mines are prosperous, and the first dredger in west Siberia was established here, but the Altai placer mining is declining. The Bogom-Darovanni reef gold mine near the Abakan river is up-to-date and flourishing. The Yenisei gold areas, one in the region between the Pit and the Angara rivers, and one in the upper basins of the Teya and Kalami, tributaries of the Stony Tunguska, are less fully developed in the absence of roads. They are, however, able to get food from the rich Minusinsk district and do not suffer from the danger of starvation, as do some mines in Yakutsk. The Bodaibo district on the Vitim river lies within the Siberian Area and produces 25% of all the gold in U.S.S.R. The gold is alluvial and 13 tons can be produced per annum; transport is a difficulty, since necessaries have to be brought from Irkutsk, but a recently constructed light railway to the Vitim river has somewhat lessened the costs. There is an assaying and gold-smelting laboratory at Bodaibo. Silver is produced in quantity in the Altai region, and platinum from Verkhoture in the Tara river district. Platinum occurs with the gold in the Pitski Mountains and in the Vitim district. Asbestos is worked in the Angara district and from the dolomite veins of the left bank of the Kamishta, a tributary of the Abakan. It is reported from other

places in the Altai, but is not at present worked (1928). Graphite of good quality exists near Turukhansk on the Yenisei and on the Lower Tunguska, but is little exploited. Mica is spasmodically worked in the Krasnoyarsk district.

There are antimony mines in the Yeniseisk district and in Minusinsk also, while radium has recently been found on the Ayakhta, a tributary of the Pit, and osmiridium is known in the Nizhne-Udinsk district. Coal is mined in the Kuznetsk beds which extend from Sudzhenka on the railway to 40 m. S. of Kuznetsk and the output in 1926–27 was 1,950 tons, mainly of coking or semi-anthracite coal used on the railway. The Minusinsk region, and Dudinsk on the Lower Yenisei have rich deposits, as yet little worked. Copper exists in the Minusinsk district, and near Verkhne-Udinsk. Salt is obtained from salt lakes in the Baraba steppe; from Lake Abakanskoe, which produces about 7,500 tons per annum, and from Ussolye near Irkutsk the annual output is about 10,000 tons. Glauber's salt (sulphate of sodium) is found in the lakes of the Baraba steppe. Hot mineral springs exist near Biisk. Lime, building-stone and clays are abundant and the Irkutsk district produces kaolin and white clay for porcelain. The jasper and porphyry of the Altai region are famous. The above is an indication only of the great mineral wealth of the Siberian Area; much of the region is as yet unsurveyed and of the mineral wealth reported (*see* Yenisei River), little is worked. Increasing colonization and consequent improvement of transport may lead to a great development of mining.

Industries and Communications.—Factories are springing up in the larger towns, the chief occupations being distilling, brewing, tanning, soap and tallow making, flour-milling, saw-milling, weaving, oil-milling, glass-making, brick and cement making and pottery. There are printing works at Omsk, Tomsk and Irkutsk, and the latter town has cigarette-case factories, steam sausage and pearl-barley factories. Rope-making is usually a *koustar* (peasant) industry, but Barnaul and Minusinsk have rope factories. The most famous glass factory is that 28 m. from Krasnoyarsk, established in 1840. Of timber industries, apart from saw-milling, Minusinsk has boat-building and Omsk, Tomsk and Irkutsk carriage-building; Omsk also manufactures railway sleepers. At Tomsk and Biisk are match factories. In the western districts *koustar* industries carried on in the peasants' cottages are common; they are less so in the east. The most noted of these are the smiths and joiners of Kuznetsk and Tomsk, the making of metal pots for milk and *barnaulkas*, or skin coats of the Barnaul district, the cedar-nut oil of Biisk, the pottery of Yeniseisk, the boot-making of the Irkutsk district. Woodwork, the dressing of sheep-skin and wool products, weaving and metal work are widespread peasant industries in the Yenisei basin and the Irkutsk district.

The Yenisei and its tributaries form the main avenue of communication north of the trans-Siberian railway, but rivers and roads alike are impassable during spring and autumn. The great military road or *Trakt* of Siberia passes through the south from Omsk via Tomsk and Krasnoyarsk to Irkutsk, and traffic along it is by post horse in summer and sledge in winter. Even this road is difficult and in places impassable in spring and autumn. In many places there are no bridges and ferries are used. The effect of the building of the railway in 1891–1905 in these conditions was marked and immediate; villages became towns with large populations in a few years, colonization and settlement near the railway increased, and the possibilities of export produced remarkable developments, *e.g.*, the dairy industry. In 1915 a branch from Novo-Sibirsk to Barnaul and Semipalatinsk was opened, with a branch line to Biisk and this line is now being prolonged to link up with the Turkestan and Orenburg-Tashkent railways. The effect on the development of Siberian products, especially grain and coal, should be marked, and settlement will be further increased. Other branch lines link Tatarskaya, 105 m. E. of Omsk, with Slavgorod and the Kulundinsk steppes, practically uninhabited in 1907, but rapidly settled during 1907–12, Taiga with Kuznetsk, and Achinsk with Minusinsk. No branch lines go northward except a short one to Tomsk.

Colonization.—The administrative centre is Novo-Sibirsk, (*q.v.*), and other towns (*q.v.*) are Barnaul, Irkutsk, Krasnoyarsk, Omsk and Tomsk, with populations from 70 to 120 thousand. Biisk has a population of 45,574 and Minusinsk of 20,403. It will be noted that all these towns are on the railway. Colonization did not begin to any extent, in the west, until the 18th century, when forts were constructed from Omsk south-eastwards along the Irtysh to protect the settlers from Kirghiz raids. Criminal, political and religious exiles were banished to Siberia up to 1900; the first mention of such exile is in 1648. In 1904 exile for political offences was again restored and is still in force (1928). Between 1823 and 1898, 700,000 exiles, with 216,000 voluntary followers passed through Tobolsk. Of the religious exiles the *raskolnik* or dissenters from the ecclesiastical changes introduced by Nikon, and from the changes introduced by Peter the Great, formed a valuable element among the colonists, being ascetic, industrious and abstemious. Some colonists were peasants ordered to settle at certain places so as to maintain road communication. But the largest element and the most important was the voluntary immigrants, who are still pushing eastwards in great numbers and gradually bringing all the fertile regions of the south of the Siberian Area under cultivation. Between 1896 and 1909 over a million immigrants settled in the Altai region and few returned. Of those settling east of the Yenisei and in the Irkutsk district, many found the climatic conditions impossible and returned westwards. Education varies with accessibility. The large towns on the railways have schools and technical institutions, but the more remote settlements and the nomads, present a difficult problem and among them the illiteracy rate is high. (R. M. F.)

SIBI, a town and district of Baluchistan. The town is now an important junction on the Sind-Peshin railway, where the Harnai line and the Quetta loop line meet, near the entrance of the Bolan pass, 88 m. S.E. of Quetta. Pop. (1901) 4,551. The district, which was constituted in 1903, has an area of 4,152 sq.m.; pop. (1901) 74,555. The greater part became British territory by the treaty of Gandamak in 1879; the rest is administered under a perpetual lease from the khan of Kalat. Political control is also exercised over the Marri-Bugti country, with an additional area of 7,129 sq. m. Pop. (1901) 38,919.

See *Sibi District Gazetteer.*

SIBIU (Ger. *Hermannstadt,* Hung. *Nagyszeben*), a town of Transylvania, Rumania, capital of the department of Sibiu. Pop. (1928) 33,400, of which 16,000 were Germans, 12,000 Rumanians, 5,400 Magyars. Sibiu is beautifully situated in the fertile valley of the Sibiu, surrounded by mountains. An old "Saxon" colony, it still retains a mediaeval Germanic appearance. The Gothic Protestant church, begun in the 14th century and finished in 1520, contains a beautiful font (1438) and a mural painting of the Crucifixion by Johannes von Rosenau (1445). The "new church," a 15th century addition, comprising the western part of the building, contains many beautiful monuments of Saxon notables. The fine 15th century town hall contains the archives of the "Saxon nation." Sibiu is the seat of an Orthodox archbishopric and of the superintendent of the Transylvanian Protestants. It contains a good museum, an Orthodox seminary, a law academy, several secondary schools and manufactures of cloth, linen, leather, caps, boots, soaps, candles, ropes and breweries and distilleries.

Sibiu was a Roman colony (Libinium) re-founded by colonists from Nuremberg in the 12th century. Its history is bound up with that of the Saxon communities in Transylvania (*q.v.*), and it was at one time capital of the principality of Transylvania.

SIBONGA, a municipality (with administration centre and 24 *barrios* or districts) of the province and island of Cebu, Philippine Islands, on the east coast 30 m. S.W. of Cebu, the provincial capital. Pop. (1918), 27,199. It is a port for the coasting trade and is connected by rail with Cebu. Corn and tobacco are the principal products. In 1918, it had 499 household industry establishments with output valued at 92,000 pesos. Of the 13 schools, 11 were public. The language is Cebu-Bisayan.

SIBSAGAR, a town and district of British India, in Assam. The town is situated on the Dikhu river, 8 m. from the Brahmaputra, and is picturesquely built round a magnificent tank. Pop.

(1921) 5,329.

The DISTRICT OF SIBSAGAR has an area of 5,202 sq.m.; population (1921), 823,197. It consists of a level plain, much overgrown with grass and jungle, and intersected by numerous tributaries of the Brahmaputra. Reserved forests extend over 1,100 square miles. Sibsagar is the chief centre of tea cultivation in the Brahmaputra valley. It contains a large number of well-managed tea-gardens, which in 1921 had a population of quarter of a million and 100,000 acres under tea with an output of nearly 50 million pounds. There are also several timber mills.

SIBTHORP, JOHN (1758–1796), English botanist, was born at Oxford on Oct. 28, 1758, the youngest son of Dr. Humphrey Sibthorp, Sherardian professor of botany at Oxford. He graduated at Oxford in 1777, and studied medicine at Edinburgh and Montpellier. In 1784 he succeeded his father in the Sherardian chair. He travelled to Göttingen and Vienna, in preparation for a botanical tour in Greece (1786). Returning to England at the end of the following year he took part in the foundation of the Linnaean Society in 1788, and published *Flora Oxoniensis* (1794). He made a second journey to Greece, but died at Bath of consumption on Feb. 8, 1796. He bequeathed his books on natural history and agriculture to Oxford university, where he founded the Sibthorpian professorship of rural economy, attaching it to the chair of botany. The task of preparing the works *Flora Graeca* and *Florae Graecae Prodromus* was undertaken by Sir J. E. Smith.

SIBYLLA, a proper name, afterwards used as a common noun (as we say, "a Daniel"); the derivation and meaning are unknown but certainly are not Greek; they are possibly Semitic. In the disturbed period preceding the development of the full classical culture; *i.e.*, about 800–600 B.C., religious movements of all sorts were common in Greece and Asia Minor, and especially, inspired prophets were numerous. Of these one of the most famous was Sibylla of Marpessus, a village near Troy, also claimed as a native of Erythrae; of her Heracleitus says (Frag. 12, Bywater) that "with her maddened mouth . . . she reaches a thousand years with her voice by the power of the god"; *i.e.*, Apollo, by whom this real or imaginary person was thought to be inspired. Numerous prophecies, generally in hexameter verse, the usual metre of Apolline oracles, were attributed to her, and her great popularity led ultimately to her multiplication, numerous places claiming, from about the 4th century on, to be her native city, or to have been visited by her, or to be the birthplace of another Sibyl of like inspiration. Varro (*ap.* Lactantius, *divin. instit.* I. 6.) gives a list of ten, which includes the famous Cumaean Sibyl, often identified with the Erythraean.

She was supposed to be the authoress of the Sibylline Oracles, which were kept in the temple of *Iuppiter Capitolinus* at Rome under the care of the *quindecimviri* (*see* ROMAN RELIGION), and consulted in emergencies by order of the Senate. Apollo loved her and granted her the gift of prophecy, and also a life of as many years as she had grains of dust in her hand; but she forgot to ask for youth, and so gradually withered away almost to nothing. It was presumably she who offered Tarquinius Superbus nine books of prophecies, and, on his declining to pay the price asked, burned first three and then three more, finally selling the remainder for the sum she originally demanded for all. (Ovid, *Metam.*, xiv., 130 et seq.; Dionysius Hal. iv. 62). Of the official collection supposed thus to have originated, one or two fragments still survive (*see* Diels, *Sibyllinische Blätter*).

Finally, Jewish and Christian apologists discovered a Judaean or Babylonian Sibyl, to whom were attributed the numerous prophecies, still extant, containing Judaeo-Christian propaganda.

See Bouché-Leclercq, *Histoire de la Divination dans l'Antiquité*, ii. p. 133 et seq.; Buchholtz in Roscher's *Lexikon*, s.v.; Wissowa, *Religion u. Kultus*, 2nd. ed. p. 534 et seq., and authorities cited there.

SIBYLLINE ORACLES, a collection of Apocalyptic writings, composed in imitation of the heathen Sibylline books by the Jews and, at a later date, by the Christians in their efforts to win the heathen world to their faith. The fact that they copied the form in which the heathen revelations were conveyed (Greek hexameter verses) and the Homeric language is evidence of a degree of external Hellenization, which is an important fact in the history of post-exile Judaism.

Book III. contains Jewish oracles relative to the Golden Age established by Roman supremacy in the East about the middle of the 2nd century B.C. (especially 175–181: *cf.* I. Macc. viii. 1–16). The evacuation of Egypt by Antiochus Epiphanes at the bidding of the Roman ambassadors suits the warning addressed to "Greece" (lines 732–740) against overweening ambition and any attempt upon the Holy City, which is somewhat strangely enforced by the famous Greek oracle, "Let Camarina be, 'tis best unstirred." Older than these are the Babylonian oracle (97–154) and the Persian (381–387). A later Jewish oracle (46–62) refers to the wars of the second Triumvirate of Rome, and the whole compilation seems to come from a Christian redactor.

Book IV. is a definite attack upon the heathen Sibyl (the Jews and Christians did not attempt to pass off their "forgeries" as genuine) as the mouthpiece of Apollo by a Jew who speaks for the Great God and yet uses a Greek review (49–114) of ancient history from the Assyrian empire. There are references to the legendary escape of Nero to Parthia (119–124) and the destruction of Jerusalem in A.D. 70 (130–136).

Book V. contains a more developed form of the myth of *Nero redivivus* in which a panegyric on him (137–141) has been brought up to date by some Jew or Christian, and eulogies of Hadrian and his successors (48–51) side by side with the legend of the miserable death of Titus in quittance of his destruction of Jerusalem (411–413) which probably represents the hope of the zealots who survived it.

The remaining books appear to be Christian (some heretical) and to belong to the 2nd and 3rd centuries.

BIBLIOGRAPHY.—Lanchester in Charles, *Apocrypha and Pseudepigrapha* vol. ii. (1913); an English trans. with notes by H. N. Bate in the S.P.C.K. *Translations of Early Documents* (1918); Schürer, *Geschichte des judischen Volkes*, iii. 555–592, who gives full bibliography. (J. H. A. H.; W. O. E. O.)

SICANI, generally regarded (together with the Elymi) as the oldest inhabitants of Sicily. Sicania and the Siculi (*q.v.*) or Siceli are mentioned in Homer (*Odyssey*, XX. 383, XXIV. 307), the latter apparently being known to the Greeks as slave dealers. From the similarity of name, it would be natural to identify the Sicani with the Siculi, but ancient authorities expressly state that they were two distinct peoples (*see* SICILY: *History, ad init.*). At first the Sicani occupied nearly the whole of the island, but were gradually driven by the Siculi into the interior and the north and north-west. The most important of the towns to which a Sicanian origin can be assigned and the site of which can be determined, are: Hyccara (*Muro di Carini*), taken and plundered by the Athenians during the Sicilian expedition (415 B.C.); and Omphakē, between Agrigentum (*Girgenti*) and Gela (*Terranova*).

SICILY (Ital. *Sicilia*), an island of the Mediterranean sea belonging to Italy, separated from the mainland by the Straits of Messina, which at their narrowest part are about 2m. in width. In shape it is roughly triangular, whence the ancient poetical name of *Trinacria,* referring to its three promontories of Pelorum (now Faro) in the north-east, Pachynus (now Passero) in the south-east, and Lilybaeum (now Boeo) in the west. Its area, exclusive of the adjacent small islands, is 9,860sq.m.; while the area of the whole group is 9,936 sq.m. Pop. (1921) 4,061,452.

The island occupies that part of the Mediterranean in which the shallowing of the waters divides that sea into two basins, and in which there are numerous indications of frequent changes in a recent geological period. The channel between Cape Bon in Tunis and the south-west of Sicily (a distance of 80m.) is, on the whole, shallower than the Straits of Messina, being for the most part under 100 fathoms in depth, and exceeding 200 fathoms only for a very short interval, while the Straits of Messina have almost everywhere a depth exceeding 150 fathoms.

The north coast is generally steep and cliff-bound and abundantly provided with good harbours, of which that of Palermo is the finest. In the west and south and in the south part of the east side, the hills are much lower and recede farther from the sea. The coast is for the most part flat, more regular in outline and less favourable to shipping, while in the east, where the sea-

bottom sinks rapidly down towards the eastern basin of the Mediterranean, steep rocky coasts prevail except opposite the plain of Catania. In the northern half of this coast the lava streams of Mount Etna stand out for a distance of about 20m. in a line of bold cliffs and promontories.

The surface of Sicily lies for the most part more than 500ft. above the level of the sea. Caltanissetta, in the centre, stands 1,900ft. above sea-level. Considerable mountains occur only in the north, where the lower slopes of all the heights form one continuous series of olive-yards and orangeries. Of the rest of the island the greater part forms a plateau varying in elevation and mostly covered with wheat fields. The only plain of any great extent is that of Catania, watered by the Simeto, in the east; to the north of this plain the active volcano of Etna rises with an exceedingly gentle slope to the height of 10,868ft. from a base 400sq.m. in extent. This is the highest elevation of the island. The steep and narrow crystalline ridge which trends north-eastwards, and is known to geographers by the name of the Peloritan mountains, does not reach 4,000ft. The Nebrodian mountains, a limestone range connected with the Peloritan range and having an east and west trend, rise to a somewhat greater height, and farther west, about the middle of the north coast, the Madonie culminate at the height of nearly 6,500ft. From the western end of the Nebrodian mountains a lower range (in some places under 1,500ft. in height) winds on the whole south-eastwards in the direction of Cape Passaro. With the exception of the Simeto, the principal perennial streams—the Salso, the Platani and the Belice—enter the sea on the south coast.

Geology.—In general, the older beds occur along the northern coast, and progressively newer and newer beds are found towards the south. Folding, however, has brought some of the older beds to the surface in the hills which lie to the north and north-east of Sciacca. The Monti Peloritani at the north-eastern extremity of the island consist of gneiss and crystalline schists; but with this exception the whole of Sicily is formed of Mesozoic and later deposits, the Tertiary beds covering by far the greater part. Triassic rocks form a discontinuous band along the northern coast, and are especially well developed in the neighbourhood of Palermo. They rise again to the surface in the southern part of the island, in the hills which lie to the north of Sciacca and Bivona. In both areas they are accompanied by Jurassic, and occasionally by Cretaceous, beds; but of the latter there are only a few small patches. In the south-eastern part of the island there are also a few very small outcrops of Mesozoic beds. The Eocene and Oligocene form a broad belt along the northern coast, very much more continuous than the Mesozoic band, and from this belt a branch extends southwards to Sciacca. Another patch of considerable size lies to the east of Piazza Armerina. Miocene and Pliocene deposits cover nearly the whole of the country south of a line drawn from Etna to Marsala; and there is also a considerable Miocene area in the north about Mistretta. Volcanic lavas and ashes of a recent geological period form not only the whole of Etna but also much of the Monti Iblei in the south.

Climate.—The climate of Sicily resembles that of the other lands in the extreme south of Europe. As regards temperature, it has the warm and equable character which belongs to most of the Mediterranean region. At Palermo in only seven of the 30 years 1871–1900, was the thermometer observed to sink below the freezing-point; frost thus occurs in the island even on the low grounds, though never for more than a few hours. On the coast snow is seldom seen, but it does fall occasionally. On the Madonie it lies till June, on Etna till July. The annual rainfall, except on the higher mountains, does not reach 30in., and it occurs chiefly in the winter months, while during June, July and August the whole rainfall does not exceed 2in., except on the slopes of the mountains in the north-east. Hence most of the streams dry up in summer. The chief scourge is the scirocco, which is experienced in its most characteristic form on the north coast.

Flora.—The flora of Sicily is remarkable for its wealth of species. The families most abundantly represented are the *Compositae, Cruciferae, Labiatae, Caryophyllaceae* and *Scrophulariaceae.* The *Rosaceae* are also abundantly represented, and among them are numerous species of the rose. The general aspect of the vegetation of Sicily, however, has been greatly affected, as in other parts of the Mediterranean, by the introduction of plants within historical times. Besides the olive, all the members of the orange tribe, the agave and prickly pear have been introduced since the beginning of the Christian era. With respect to vegetation and cultivation three zones may be distinguished. The first reaches to about 1,600ft. above sea-level, the upper limit of the members of the orange tribe; the second ascends to about 3,300ft., the limit of the growth of wheat, the vine and the hardier evergreens; and the third, that of forests, reaches from about 3,300ft. upwards. Among other trees may be mentioned the sumach, the date-palm, the plantain, various bamboos, cycads, and the dwarf-palm. The *Arundo Donax,* the tallest of European grasses, is largely grown for vine-stakes.

Population.—For the area and population of the several provinces *see* ITALY. Between 1881 and 1901 the population increased at the rate of 20·5% and between 1901 and 1921 at the rate of 13·8%. The average density is extremely high for a country which lives almost exclusively by agriculture, and is much higher than the average for Italy in general.

Agriculture.—Two types of agriculture prevail in Sicily—the extensive and the intensive. The former covers mainly the interior of the island and half the southern coast, whilst the latter is generally adopted on the eastern and northern coasts. Large holdings of well over 1,000ac. are indispensable to the profitable pursuit of extensive agriculture.

Intensive agriculture in Sicily is limited to fruit trees and fruit-bearing plants. Large extents of land along the coasts are exclusively cultivated as vineyards, or as olive, orange and lemon groves. The by-products of the citrus-essences, citrate of lime, etc., are also of some importance. Vegetables are grown chiefly in the neighbourhood of large cities. Almonds are freely cultivated, and they seem to be the only trees susceptible also of cultivation upon the *latifondi* together with grain. A large export trade in almonds is carried on with north and central Europe. Hazelnuts are grown in woods at a level of more than 1,200ft. above the sea. These also are largely exported to central Europe for use in confectionery. The locust bean (used for forage), figs and peaches are widely grown, while in certain zones the pistachio and the manna-ash yield rich returns. On the more barren soil the sumach shrub, the leaves of which are used for tanning, and the prickly pear grow freely. The latter fruit constitutes, with bread, the staple food of the poorest part of the rural population for several months in the year.

Climatic conditions prevent cattle-raising in Sicily from being as prosperous an undertaking as in central Italy. The total number of bullocks in the island is calculated to be 221,357 (1918). Sheep and goats, which subsist more easily on scanty pasturage, are more numerous, the total number being calculated at 1,553,623. The wool harvest is scanty, and the production of butter a negligible quantity, though there is abundance of the principal product of Sicilian pasture lands, cheese of various kinds, for which there is a lively local demand. The Sicilian race of horses would be good but has degenerated in consequence of insufficient nourishment and overwork. A better breed of horses is being obtained by more careful selection, and by crossing with Arab and English stallions imported by the Government.

The absence of forests, which cover hardly 3% of the total area of the island, constitutes a serious obstacle to the prosperity of Sicilian pastoral and agrarian undertakings. The few remaining forests are almost all grouped around Etna and upon the high zone of the Madonian mountains. Plans for reforesting certain areas have been advanced.

In that part of the island which is cultivated intensively some 3,084,000hectol. of wine were produced in 1926 and had not the phylloxera devastated the vineyards during the last decade of the 19th century the production would be considerably higher; 132,900 tons of olives, 162,200hectol. of olive oil and 595,100 tons of oranges and lemons were also produced. The zone of the *latifondi,* or extensive culture, yielded 143,000 tons of beans in 1926. The total exports in 1925 were half as much again as

the imports, and about 70% of the former were agricultural products.

Mining.—The most important Sicilian mineral is undoubtedly sulphur, mined principally in Caltanissetta and Girgenti, and in minor quantities in Palermo and Catania (208,447 tons in 1925).

Another Sicilian mineral industry is the production of common salt and rock-salt. The centre of the asphalt mining industry is the province of Syracuse (200,000 tons in 1925). Pumice stone is also exported from Lipari.

Other Industries.—Deep-sea fisheries give employment to many Sicilians, who exercise their calling not only off the coasts of their island, but along the north African shore, from Morocco to Tripoli. In 1914 the total number of fishermen was 46,583, as against 127,558 for the whole of Italy, and 8,789 tons of fish were caught. Only 32 tons of coral were obtained in 1914, for a value of £15,168—about one-tenth of the quantity for 1900. The sponge divers brought up sponges valued at £24,000. The estimated hauls of tunny fish were 2,088 tons, valued at £72,780.

The majority of the Sicilian industries are directly connected with various branches of agriculture. Such, for instance, is the preparation of the elements of citric acid. The total production of raw citrate of calcium was 82,190 tons in 1924–5, of which 4,678 tons were exported, and 1,020 of tartaric acid; 2,780 tons of citric acid, produced at Palermo and Linate in Lombardy, were also exported. Older and more flourishing is the Marsala industry. Marsala wine is a product of the western vineyards situated slightly above sea-level. Another flourishing Sicilian industry carried on by a large number of small houses is that of preserving vegetables in tins. An artificial lake at Piana dei Greci above Palermo is used for the production of electric power and for the irrigation of the Conca d'Oro. Good furniture is made at Palermo and lace (mostly from old patterns) at several places.

Communications.—Before 1860 there was no railway in Sicily. The total length of Sicilian railways is now nearly 1,200m., all single lines. Their construction was rendered very costly by the mountainous character of the island. Messina is connected with the railway system of the mainland by ferry-boats from Villa San Giovanni and Reggio. From Messina lines run along the northern coast to Palermo, and along the east coast, *via* Catania to Syracuse: the latter line is prolonged along the south of the island *via* Canicatti to Aragona Caldare, Girgenti and Porto Empedocle. From Catania another line runs westward through the centre of the island *via* San Caterina Xirbi (with a branch to Canicatti) to Roccapalumba (with a branch to Aragona Caldare), and thence northwards to Termini, on the line between Messina and Palermo. This is the direct route from Catania to Palermo. From Catania begins the line round Etna following its south, west and north slopes, and ending at Giarret Riposto on the east coast railway. From Valsavoia (14m. south of Catania on the line to Syracuse) a branch line runs to Caltagirone. From Palermo a line runs southwards to Corleone and San Carlo (whence there are diligences to Sciacca on the south coast) and another to Castelvetrano, Marsala and Trapani. Narrow-gauge railways have been constructed, especially in the south, so that Catania is linked up with Ragusa and Castelvetrano with Porto Empedocle and Licata. A steam tramway runs from Messina to the Faro at the north-east extremity of the island, and thence along the north coast to Barcelona, and another along the east coast from Messina to Giampilieri. Communications by sea are important. A steamer leaves Naples every night for Palermo, and *vice versa*. Palermo, Messina and Catania (*qq.v.*) are the most important harbours. Porto Empedocle and Licata share with Catania most of the sulphur export trade, and the other ports of note are Marsala, Trapani, Syracuse.

Economic, Intellectual and Moral Conditions.—As a general rule, trade and the increase of production have not kept pace with the development of the ways of communication. The poverty of the Sicilian population is accentuated by the unequal distribution of wealth among the different classes of society. About one-fifth of the total area of the island belongs to 1,025 individuals, and half of this is properly cultivated, the rest being badly or insufficiently so. But the proportion of the area of the island used for agricultural purposes is very high—no less than 94·6%. A small but comparatively wealthy class—composed principally of the owners of *latifondi*—resides habitually in the large cities of the island, or even at Naples, Rome or Paris.

Emigration only attained serious proportions within the last decade of the 19th century. In 1897 the emigration from the island was 15,994; in 1898, 21,320; and in 1899, 24,604. Since then it has increased: in 1905 the emigrants numbered 106,000, and in 1906, 127,000 (3·5% of the population). Of these about three-fourths were adults; but the rapid increase in the population has more than covered the deficiency.

Emigration has fallen since the World War. When in 1860, Sicily was incorporated in the Italian kingdom, hardly a tenth of the population could read and write. Upon the completion of unity, elementary schools were founded everywhere; but, though education was free, the indigence of the peasants in some regions prevented them from taking full advantage of the opportunities offered. In 1921, 51% of the whole population over six years old, and in 1925, 74% of the persons married, could read. Brigandage of the classical type has disappeared from Sicily, and energetic proceedings are now, for the first time, being taken against the Mafia (*q.v.*). (G. G. CH.; G. MO.; T. A.)

New Measures.—The institution in 1925 of the *Provveditorato alle opere pubbliche in Sicilia* (a special commission for public works) has rendered co-ordination and rapid action possible. Over 1,200 miles of high-roads are being improved, and over 450 miles of new roads are to be finished by 1931. Important harbour works, schools, aqueducts and other public works have been undertaken, the total cost of which will be some £8,000,000. Marshy land is being drained and new villages are being built. Much is being done in the way of co-operation and the granting of credits, especially since the Bank of Sicily ceased to be a bank of issue, and became (like the Bank of Naples and the Monte dei Paschi at Siena) a public credit institution. It was thus able to create an association for the cultural and economic development of the island, out of which has already grown a regular motor service for tourists along the main routes. The National Association for the interests of southern Italy maintained in 1925–26 159 day-schools, frequented by 14,588 pupils, and 742 schools for adults, which in the first five years were frequented by 162,955 pupils.

Archaeology.—The pre-Hellenic inhabitants of Sicily are called by classical authors Sicani or Siculi, variant names of kindred tribes who doubtless migrated at much the same time from north Africa. It is, however, very convenient to retain the two names, to apply the term Sicanian to the stone age, and to reserve Siculan for the Chalcolithic and the bronze and iron ages, the first Siculan period being Chalcolithic, the second Siculan being bronze age, while the beginnings of the iron or the third Siculan period will be from 900 to 700 B.C., and the beginning of a fourth Siculan may be placed at 700 B.C. when the native civilization is hybridized with the Greek.

The Sicanian Period.—Pottery incised with geometrical designs, including one bell-beaker, the Sicanian period is known principally from two sites, Stentinello and Matrensa. Stone implements from these places were of poor quality and there were no other objects of interest except the pottery, which is hand-made and baked in an open fire. The surface is blackish-grey, and the ornament upon it, which looks as if it were merely incised, has a strange regularity produced by real stamps, not by puncture by bone awls. This phenomenon is unique at this early time. Most unfortunately no vases have been recovered intact, but from the fragments it is inferred that there were, at any rate, hemispherical bowls, basins with ring handles and conical vases with a ring foot. The pottery of the caverns at Villafrati and Moarda belongs to a later stage of the Neolithic. The finding of a bell-beaker connects it with the civilization of the dolmen-builders.

Many parts of Sicily still remain to be explored for traces of the Sicanian period, but so far as the present material goes, the first Siculan does not seem to have evolved from the Sicanian, or, if it has, the steps are still missing; for all the outward and

material evidence of the two civilizations shows them to be very different. A few rock-hewn tombs of the first Siculan period have been discovered near Palermo and a considerable number near Girgenti, but the largest cemeteries were found by Paolo Orsi in the Syracusan district. The principal sites are those of Castelluccio, Melilli, Monte Racello, Monte Tabuto, Vallelunga and Monte Salia. The typical burial was in a rock-hewn chamber, the construction varying according to the nature of the ground, so that at Monte Tabuto the dead were buried in disused flint-mines, while at Monte Racello natural caverns were enlarged for the purpose, and actual surface-graves were even formed out of slabs on the top of the broken ground. At Castelluccio, however, which may be taken as the standard case, the circular or elliptical chambers were hewn in a vertical face of rock and entered by a short horizontal corridor.

Each chamber contained many skeletons, in one case no less than twenty-six. They were invariably buried in the squatting position, accompanied by a small number of weapons and ornaments and a regular equipment of pottery. It seems that the idea was to seat them as at a banquet, with large jars beside them to hold water, and smaller decorated cups out of which to drink it. The weapons and implements were sometimes of stone, especially flint, sometimes of copper in primitive forms as if the Neolithic period was only just past and hardly forgotten. Of personal ornaments there were few. Of pottery, all hand-made, there were three kinds, viz., a rough household ware, pots of a better clay coated with a red or yellow slip and—far the most important—a ware covered either with a cream-coloured or dark-red slip on which very simple geometric patterns were executed in dark-brown. This painted ware is the peculiar distinction of the first period. Nothing very closely resembling it is known anywhere else.

A curious fact is that an elaborately carved bone ornament found at Castelluccio is so nearly identical with one found in the second city of Hissarlik that the two must have had a common origin.

The Second Siculan Period.—The second Siculan period of the full bronze age is represented at its best by the cemeteries of Plemmirio, Milocca, Cozzo Pantano and Thapsos close to Syracuse, and by Caldare and Cannatello near Girgenti. All these contain Mycenaean imports, of which the earliest are clearly to be dated as late Minoan third period. (*See* AEGEAN CIVILIZATION.) Bronze swords from the same sites are also quite definitely of Mycenaean origin, and prove the existence of a considerable direct trade with the Aegean. To Aegean influence is probably due the remarkable development in tomb-construction which characterizes the second Siculan. All the cemeteries consist of rock-hewn tombs; the construction is no more than a natural and logical evolution from the rock-tombs of the first Siculan. The roof of the chamber is sometimes of tholos form, which again recalls Aegean precedents. Inside it is usually elliptical; a raised bench cut in the rock runs round it, and niches are often hewn in the walls. Within this chamber the dead were buried as if seated at a stately banquet with the finest products of Sicilian potters for their table service and the rarest of foreign drinking cups. The size of the great food-basins is remarkable; they are often two and a half or three feet in height.

The native pottery is made principally in a grey-faced ware ornamented with moulded strips or with a few sparsely incised lines; there is also a yellow-faced ware. Painted ware is unknown. The shapes are very few—a high stand, a biconical cup with side handles, a conical cup, a jug and one or two large water jars. Foreign trade added the amphora, pyxis, pedestalled cup and stirrup-handled vase, and gave a great impetus to metal-working. Swords, daggers and even basins were imported, but the various hoards of bronze objects show that a great quantity of native work must have existed. The tombs, however, were systematically ransacked for metals, after the Roman time. Another proof of foreign influence is the introduction of the fibula, which appears at Cozzo Pantano for the first time. The earliest fibulae are of two types, the plain violin-bow with bamboo-knots and the harp-shaped or elbowed fibula, each made in a very massive form.

These four cemeteries near Syracuse must be assigned on the evidence of the foreign imports to the 14th and 13th centuries B.C. Caldare and Cannatello, further inland, date from the 12th to 11th centuries. Latest of all, and marking the last stage of the bronze age, is Cassibile, a large cemetery near Syracuse, in which there were no Mycenaean products and the fibulae were perceptibly less archaic.

Intermediary Period.—Next in chronological order come four sites between Syracuse and Girgenti which span the gap between the bronze and iron ages, the later graves in them belonging entirely to the early iron age. On Orsi's system they are to be classed as intermediate between the second and the third Siculan. These are Pantalica, Grammichele, Caltagirone and Monte Dessueri. Here the form of the tomb is already beginning to be modified, the number of burials in each grave is smaller, and the tomb-furniture is later in character. This is especially perceptible in the personal ornaments; the fibulae have quite changed, for in place of the primitive violin-bow the simple rounded bow is predominant and more sophisticated forms, like the eyed harp-fibula, begin to appear.

In addition to arm-rings and finger-rings and mirrors of bronze there are now found, though rarely, gold-rings, silver armlets and silver rings. Rectangular bronze "razors" come into use, like those known in Italy but of different origin. There are no weapons, perhaps owing to the rifling of the graves, but flame-shaped and leaf-shaped bronze knives occur. The native pottery is very varied in form at this time, the best of it being in a ware faced with red haematite. Feather-patterned ware soon goes out of fashion; the impulse towards originality is killed by a fondness for geometrically painted wares, the products of new Greek schools. These begin to appear sporadically about 900 B.C.

The Iron Age.—On a site like Pantalica, with a range of several centuries, we pass into the iron age without any striking changes. Modifications occur in the types of the fibulae and there is a gradual, but quite perceptible, deterioration of the pottery. All the bronze-age types of fibulae gradually give way to later forms, of which the most general and popular is the two-eyed serpentine, which continues in use down to 500 B.C.

The first appearance of this fibula marks a distinct chronological point; it is the beginning of the early iron age, and if the contents of tombs belonging to this stage are isolated, and examined separately from the rest, then certain definite characteristics begin to appear. The old Siculan civilization of the great days survives in a much impoverished form; it has entered upon its decadence. The architecture has lost all its beauty and elaboration of detail. Within a very simple chamber the dead are no longer seated at a banquet, but extended at full length on the ground with their heads resting on a block of stone; and the objects buried with them consist of little but a few small water-jars and trumpery pots. We now pass into Orsi's third period, early in the 9th century. The partial regeneration of Siculan life which begins gradually in the 9th century is entirely due to Greek influence, through trade, which preceded any actual colonization by fully 150 years. Thus everything of interest in Siculan life from the 9th century to the 5th B.C. is either a Greek importation or the direct imitation of a Greek original.

From a number of sites, the most important of which were Lentini (the ancient Leontinoi), Licodia and Finocchito, were obtained examples of geometrically painted vases, the earliest of which are of pure Dipylon style, while the latest are a hybridized product which may be termed Graeco-Siculan. A characteristic vase shown from Lentini, belongs to the third Siculan period. If not an actual importation it is a close copy of some Dipylonic original at least as early as the 8th century B.C. At Lentini there were still earlier types, little oenochoae and askoi painted with the simplest kind of linear designs. This style is not found even in the first of the Greek colonies, and must therefore, precede the period of colonization. Orsi is evidently justified in assigning it to the 8th and possibly to the 9th century B.C.

The introduction of these new models led to the imitation of purely Greek shapes by the native potters, so that oenochoae and askoi were copied in the rough country ware, and to a closer study of decorative designs, which resulted in the production of

a new kind of white-faced ware with geometrical patterns painted upon it. This gradually improved in technique until it reached its high-water mark in the late third and early fourth Siculan periods. The Graeco-Siculan ware continued in use until it was finally replaced about 500 B.C. by purely Greek imported vases.

BIBLIOGRAPHY.—The original authority for this entire article is to be found in the various writings of Paolo Orsi. The references to the different Italian publications in which they appeared are given in T. E. Peet, *The Stone and Bronze Ages in Italy;* and D. Randall-MacIver, *The Iron Age in Italy* (1927). These two works contain the literature of the subject in English. (D. R.-M.)

HISTORY

Original Inhabitants.—The island (Σικελία, *Sicilia*) obviously takes its name from the Sicels (Σικελοί, *Siculi*), a people whom we find occupying a great part of the island, chiefly east of the river Gela. We are told that they found in the island a people called Sicans (Σικανοί, *Sicani*); but the outstanding fact is that archaeologically no substantial difference between them can be found; and probably both are branches of the Libyco-Iberian stock.

In the north-west corner of the island we find a small territory occupied by a people who seem to have made much greater advances towards civilized life, the Elymi, who probably came from Asia Minor, where they had already fallen under Greek influence. Their towns were Eryx and Segesta.

Foreign Colonists.—The Greeks were not the first colonizing people who were drawn to the great island. As in Cyprus and in the islands of the Aegean, the Phoenicians were before them. Numerous small trading settlements grew up on promontories and small islands all round the coast, not much later, no doubt, than their colonies in North Africa and their factories in southern Spain. These were unable to withstand the Greek settlers, and the Phoenicians of Sicily withdrew step by step to form three considerable towns in the north-west corner of the island near to the Elymi, at the shortest distance by sea from Carthage—Motya, Solus and Panormus (*see* PALERMO).

Greek Colonization.—This begins with the foundation in 735 B.C., of the Sicilian Naxos by Chalcidians of Euboea under Theocles. The next year Corinth began her system of settlement in the west: Corcyra, the path to Sicily, and Syracuse were planted as parts of one enterprise. From this time, for about 150 years, Greek settlement goes steadily on. The east coast, nearest to Greece and richest in good harbours, was occupied first. Here, between Naxos and Syracuse, arose the Ionian cities of Leontini and Catana (729 B.C.), and the Dorian Megara Hyblaea (726 B.C.). Settlement on the south-western coast began in 691–90 B.C. with the joint Cretan and Rhodian settlement of Gela, and went on in the foundations of Selinus (the most distant Greek city on this side), of Camarina (598 B.C.), and in 582 B.C. of the Geloan settlement of Acragas (Agrigentum, Girgenti), planted on a high hill, a little way from the sea, which became the second city of Hellenic Sicily. On the north coast the Ionian Himera (founded in 648 B.C.) was the only Greek city in Sicily itself, but the Cnidians founded Lipara in the Aeolian Islands. At the north-east corner, opposite to Italy, and commanding the strait, arose Zancle, a city of uncertain date (first quarter of the 8th century B.C.) and mixed origin, better known as Messana (Messene, Messina).

But there were also independent Sicel towns in the interior, and there was a strong religious intercommunion between the two races. Sicel Henna (Enna, Castrogiovanni) is the special seat of the worship of Demeter and her daughter.

In the 7th century B.C. and the early part of the 6th the Greek cities of Sicily had their full share in the general prosperity. Their political constitutions were aristocratic, but civil dissensions led very early to the rise of tyrants. The most famous if not the first is Phalaris (*q.v.*) of Acragas (Agrigentum). Under his rule the city at once sprang to the first place in Sicily, and he was the first Siceliot ruler who held dominion over two Greek cities, Acragas and Himera. This time of prosperity was also a time of intellectual progress. Stesichorus of Himera (*c.* 632–556 B.C.) holds a great place among the lyric poets of Greece. The architecture and sculpture of this age have also left some of their most remarkable monuments among the Greek cities of Sicily, especially at Selinus. In this period, too, begins the fine series of Sicilian coins (*see* NUMISMATICS: *Sicily*).

Growth of Tyrannies.—A change began in the 6th century. The Phoenician settlements in Sicily became dependent on Carthage, whose growing power began to be dangerous to the Greeks of Sicily. Meanwhile the growth of tyrannies in the Greek cities was beginning to group several towns together under a single master, and thus to increase the greatness of particular cities at the expense of their freedom. Thus Theron of Acragas (488–472), acquired also, like Phalaris, the rule of Himera. Anaxilaus of Rhegium, occupied Zancle and changed its name to Messana. The Deinomenid dynasty, began at Gela in 505, and was in 485 translated by Gelon (*q.v.*) to Syracuse. That city now became the centre of a greater dominion over both Greeks and Sicels than the island had ever before seen. But Gelon, like several later tyrants of Syracuse, takes his place—and it is the redeeming point in the position of all of them—as the champion of Hellas against the barbarian. Gelon was followed by his brother Hieron (478–467), the special subject of the songs of Pindar, whose influence extended as far as Italy, where he supported Locri against Anaxilaus of Rhegium and Cumae against the Etruscans. Acragas meanwhile flourished under Theron; but a war between him and Hieron led to slaughter and new settlement at Himera.

None of these tyrannies was long-lived. The power of Theron fell to pieces under his son Thrasydaeus. When the power of Hieron passed in 467 B.C. to his brother Thrasybulus the freedom of Syracuse was won by a combined movement of Greeks and Sicels. About 50 years of great prosperity followed. Art, science, poetry had all been encouraged by the tyrants. Empedocles of Acragas is best known from the legends of his miracles and of his death in the fires of Aetna; but he was not the less philosopher, poet and physician, besides his political career. Gorgias (*q.v.*) of Leontini had a still more direct influence on Greek culture, as father of the technical schools of rhetoric throughout Greece. Architecture, too, advanced, and the Doric style gradually lost somewhat of its ancient massiveness.

During this time of prosperity there was no dread of Carthaginian inroads. But now comes the great Sicel movement under Ducetius, who, between force and persuasion, came nearer towards uniting his people into one body than had ever been done before by founding the new city of Palicae in the plain. His power grew, and Acragas could withstand him only by the help of Syracuse. But his work was cut short by his death in 440, though his foundation of *Kale Akte* lived on, and we presently hear of Sicel towns under kings and tyrants, all marking an approach to Greek life.

Interference of Athens.—Sicilian isolation was broken in upon by the great Peloponnesian War. The Siceliot cities were drawn into alliance with one side or the other, till the main interest of Greek history gathers for a while round the Athenian attack on Syracuse.

The interference of Athens in Sicilian affairs in 415 was partly in answer to the cry of the exiles of Leontini, partly to a quite distinct appeal from the Elymian Segesta. That city, an ally of Athens, asked for Athenian help against its Greek neighbour Selinus.

The details of the great Athenian expedition (415–413) belong partly to the political history of Athens (*q.v.*), partly to that of Syracuse (*q.v.*). But its results make it a marked epoch in Sicilian history, and the Athenian plans, if successful, would have changed the whole face of the West. The whole war was remarkable for the large entrance of the barbarian element into the Athenian reckonings; it was undertaken on behalf of Segesta; the Sicels gave Athens valuable help; the greater barbarian powers out of Sicily also came into play. Some help actually came from Etruria. But Carthage was more far-sighted. If Syracuse was an object of jealousy, Athens, succeeding to her dominion, creating a power too nearly alike to her own, would have provoked far greater jealousy. So Athens found no active support save at Naxos and Catana, though Acragas, if she would not help the invaders, at least gave no help to her own

PICTURESQUE SICILIAN VIEWS

1. Ruins of a castle built in 396 B.C., high on the hillside, overlooking Taormina; formerly the Acropolis of Tauromenium
2. Looking down on Girgenti (Agrigentum) from the rock of Athena. The rock of Athena is identified by some scholars with the Acropolis of the Greek city of Acragas
3. Old house and courtyard in Taormina, the Casa Floresta
4. Taormina seen from the sea. The hill of Mola may be seen in the background
5. Cloisters of the Benedictine Monastery of Monreale. The arches, decorated with mosaic, are supported by 216 pairs of columns. The style is Southern Italian Romanesque
6. Cathedral at Palermo, completed in 1185 by Archbishop Walter of the Mill, an Englishman. The arch on the left is one of the two which connect the cathedral with the old Campanile

rival. But after the Spartan Gylippus came, almost all the other Greek cities of Sicily were on the side of Syracuse. The main result of the expedition, as regards Sicily, was to bring the island more thoroughly into the thick of Greek affairs. Syracuse, threatened with destruction by Athens, was saved by the zeal of her metropolis Corinth in stirring up the Peloponnesian rivals of Athens to help her, and by the advice of Alcibiades after his withdrawal to Sparta. All chance of Athenian dominion in Sicily or elsewhere in the west came to an end. Syracuse repaid the debt by good service to the Peloponnesian cause, and from that time the mutual influence of Sicily and old Greece is far stronger than in earlier times.

Carthaginian Wars.—But before the war in old Greece was over, 70 years after the great victory of Gelon (410), the Greeks of Sicily had to undergo barbarian invasion on a vaster scale than ever. The disputes between Segesta and Selinus called in these enemies also. Carthage, after a long period of abstention from intervention in Sicilian affairs, and the observance of a wise neutrality during the war between Athens and Syracuse, stepped in as the ally of Segesta, the enemy of her old ally Selinus. Her leader was Hannibal, grandson and avenger of the Hamilcar who had died at Himera. In 409, at the head of a vast mercenary host, he sailed to Sicily, attacked Selinus (*q.v.*), and stormed the town after a murderous assault of nine days. Thence he went to Himera, with the object of avenging his grandfather. By this time the other Greek cities were stirred to help, while Sicels and Sicans joined Hannibal. At last Himera was stormed, and 3,000 of its citizens were solemnly slaughtered on the spot where Hamilcar had died. Hannibal then returned to Carthage after an absence of three months only. The Phoenician possessions in Sicily now stretched across the island from Himera to Selinus. The next victim was Acragas, against which another expedition sailed in 406 under Hannibal and Himilcon; the town was sacked and the walls destroyed, and the population took refuge at Gela.

Meanwhile the revolutions of Syracuse affected the history of Sicily and of the whole Greek world. Dionysius (*q.v.*) the tyrant began his reign of 38 years in the first months of 405. Almost at the same moment, the new Carthaginian commander, Himilcon, attacked Gela and Camarina. Dionysius, coming to the help of Gela, was defeated, and evacuated both it and Camarina, leaving them for the Carthaginians to plunder. He was charged (no doubt with good ground) with treachery. But now a peace, no doubt arranged at Gela, was formally concluded. Carthage was confirmed in her possession of Selinus, Himera and Acragas, with some Sican districts which had opposed her. The people of Gela and Camarina were allowed to occupy their unwalled towns as tributaries of Carthage. Leontini, latterly a Syracusan fort, as well as Messana and all the Sicels, were declared independent, while Dionysius was acknowledged as master of Syracuse. Under him Sicily became for the first time the seat of a great European power, while Syracuse, as its head, became the greatest of European cities.

The reign of Dionysius (405–367) is divided into marked periods by four wars with Carthage, in 398–397, 392–391, 383–378 and 368–367. In the first Dionysius took and destroyed the Phoenician stronghold of Motya; but Himilcon founded Lilybaeum as a substitute on the mainland in the following year (396), destroyed Messana, founded the hill-town of Tauromenium above Naxos for Sicels who had joined him, defeated the fleet of Dionysius off Catana and besieged Syracuse. But the Carthaginians suffered from pestilence in the marshes of Lysimeleia; and after a masterly combined attack by land and sea by Dionysius Himilcon went away utterly defeated, taking with him his Carthaginian troops and forsaking his allies. Gela, Camarina, Himera, Selinus, Acragas itself, became subject allies of Dionysius. The Carthaginian dominion was cut down to what it had been before Hannibal's invasion. Dionysius then planted mercenaries at Leontini, conquered some Sicel towns, Henna among them, and made alliances with others. He restored Messana, peopling it with motley settlers, among whom were some of the old Messenians from Peloponnesus. But yielding to Spartan opposition Dionysius moved them to the north coast, where they founded Tyndaris. He took the Sicel Cephaloedium (Cefalù), and even the old Phoenician border-fortress of Solous was betrayed to him. He beat back a Rhegine expedition; but his advance was checked by a failure to take the new Sicel settlement of Tauromenium. His enemies of all races now declared themselves. Many of the Sicels forsook him; Acragas declared herself independent; Carthage again took the field.

In the war of 392–391 most of the Sicels joined the Carthaginian leader Magon; but he was successfully withstood at Agyrium by Agyris, the ally of Dionysius. The two tyrants drove Carthage to a peace by which she abandoned all her Sicel allies to Dionysius, who founded the towns of Hadranum and Halaesa for them. This time he took Tauromenium and settled it with his mercenaries.

Dionysius in 390–387 warred against the Italiot cities in alliance with their Lucanian enemies. Rhegium, Croton, the whole toe of the boot, were conquered. In the Adriatic he helped Hellenic extension, desiring no doubt to secure the important trade route into central Europe. He planted directly and indirectly some settlements in Apulia, while Syracusan exiles founded the more famous Ancona. He helped the Parians in their settlements of Issa and Pharos; he took into his pay Illyrian warriors with Greek arms, and helped the Molossian Alcetas to win back part of his kingdom. He was even charged with plotting with his Epirot ally to plunder Delphi, and sent a fleet along the west coast of Italy, to carry off the wealth of the great temple of Caere.

In the third war (383–378) Dionysius seems for once to have had his head turned by a first success. His demand that Carthage should altogether withdraw from Sicily was met by a crushing defeat. Then came a treaty by which Carthage kept Selinus and part of the land of Acragas. Dionysius had also to pay 1,000 talents. In the last years of his reign he gave help to Sparta against Thebes, sending Gaulish and Iberian mercenaries to take part in Greek warfare. His last war with Carthage, which began with an invasion of western Sicily, and which was going on at his death in 367 B.C., was ended by a peace by which the Halycus remained the boundary.

The tyranny of Dionysius fell, as usual, in the second generation; but it was kept up for ten years after his death by the energy of Philistus, now minister of his son Dionysius the younger. It fell with the return of the exile Dion in 357.

Between the death of Dion in 354 and the coming of Timoleon in 344 we hear of a time of confusion in which Hellenic life seemed likely to die out. The cities, Greek and Sicel, were occupied by tyrants. The work of Timoleon (*q.v.*), whose headquarters were first at Tauromenium, then at Hadranum, was threefold—the immediate deliverance of Syracuse, the restoration of Sicily in general to freedom and Greek life, and the defence of the Greek cities against Carthage. The great victory of the Crimissus in 339 led to a peace with Carthage with the old frontier; but all Greek cities were to be free, and Carthage was to give no help to any tyrant.

During the 20 years after the death of Timoleon (336–317) the Carthaginians played off one city and party against another, and Agathocles (*q.v.*), following the same policy, became in 317, by treachery and massacre, undisputed tyrant of Syracuse, and spread his dominion over many other cities. Acragas, strengthened by Syracusan exiles, now stands out again as the rival of Syracuse. The Carthaginian Hamilcar won many Greek cities to the Punic alliance. Agathocles, however, with Syracuse blockaded by a Carthaginian fleet, planned to carry the war into Africa.

For more than three years (310–307) each side carried on warfare in the land of the other. Carthage was hard pressed by Agathocles, while Syracuse was no less hard pressed by Hamilcar. Agathocles won many battles and towns; he quelled mutinies of his own troops; by inviting and murdering Ophellas, lord of Cyrene, he doubled his army and brought Carthage near to despair. Meanwhile Syracuse, all but lost, had driven back Hamilcar, and had taken him prisoner in an unsuccessful attack on Euryelus, and slain him when he came again with the help of the Syracusan exile Deinocrates. Acragas, deeming Agathocles and the barbarians alike weakened, proclaimed freedom for the Sicilian cities under her own headship. But her hopes perished

when Agathocles came back from Africa, landed at Selinus, and marched to Syracuse, taking one town after another. He now relieved Syracuse from the Carthaginian blockade; his mercenaries gained a victory over Acragas; and he sailed again for Africa; when fortune turned against him there he left his sons and his army to death, bondage or Carthaginian service, and came back to Sicily almost alone. Yet he could still gather a force which enabled him to seize Segesta, to slay or enslave the whole population and to settle the city with new inhabitants. A peace with Carthage, with the old boundary, secured Agathocles in the possession of Syracuse and eastern Sicily (301).

At some stage of his African campaigns Agathocles had taken the title of king. In his old age he took a wife of the house of Ptolemy; he gave his daughter Lanassa to Pyrrhus, and established his power as the first Sicilian ruler of Corcyra.

The Appearance of Rome.—On the death of Agathocles tyrants sprang up in various cities. Acragas, under its king Phintias, won back for the moment somewhat of its old greatness. By a new depopulation of Gela, he founded the youngest of Siceliot cities, Phintias, at the mouth of the southern Himera. Messana was seized by the disbanded Campanian mercenaries of Agathocles (*c.* 282), who proclaimed themselves a new people in a new city by the name of Mamertines, children of Mamers or Mars. Messana became an Italian town—"Mamertina civitas."

The Campanian occupation of Messana is the first of the chain of events which led to the Roman dominion in Sicily. Pyrrhus (*q.v.*) came as the champion of the western Greeks against all barbarians, whether Romans in Italy or Carthaginians in Sicily. His Sicilian war (278–276) was a mere interlude between the two acts of his war with Rome.

The Greek king, on his way back to fight for Tarentum against Rome, had to cut his way through Carthaginians and Mamertines in Roman alliance. His saying that he left Sicily as a wrestling-ground for Romans and Carthaginians was the truth of the matter. Very soon came the first war between Rome and Carthage (the "First Punic War").

Sicily never had a more hopeful champion than Hieron II. of Syracuse, who, claiming descent from Gelon, pressed the Mamertines hard. He all but drove them to the surrender of Messana; he even helped Rome to chastise her own rebels at Rhegium.

The exploits of Hieron had already won him the title of king (270) at Syracuse; but his alliance with Rome (263) marks a great epoch in the history of the Greek race. He was the first of Rome's kingly vassals. His only obligation was to give help to the Roman side in war; within his kingdom he was free.

First Punic War.—During the 23 years of the First Punic War (264–241) the rest of the island suffered greatly. The war for Sicily was fought in and around Sicily, and the Sicilian cities were taken and retaken by the contending powers (*see* PUNIC WARS). By the treaty which ended the war in 241 Carthage ceded to Rome all her possessions in Sicily, which thus became the first Roman province.

We have no picture of Sicily in the first period of Roman rule. One hundred and seventy years later, several towns within the original province enjoyed various degrees of freedom, which they had doubtless kept from the beginning. Panormus, Segesta, with Centuripae, Halaesa and Halicyae, once Sicel but now Hellenized, kept the position of free cities. The rest paid tithe to the Roman people as landlord. The province was ruled by a praetor sent yearly from Rome. It formed, as it had even from the Carthaginian period, a closed customs district. Within the Roman province the new state of things called forth much discontent; but Hieron remained the faithful ally of Rome through a long life. On his death (215) and the accession of his grandson Hieronymus, his dynasty was swept away by the last revolution of Greek Syracuse. The result was revolt against Rome, the great siege and capture of the city, the addition of Hieron's kingdom to the Roman province. Two towns only, besides Messana, which had taken the Roman side, Tauromenium and Netum, were admitted to the full privileges of Roman alliance. Some towns were destroyed; the people of Henna were massacred. Acragas, again held for Carthage, was the centre of a campaign (214–210).

Roman Sicily.—Independent Sicilian history now comes to an end for many ages. The allied cities kept their several terms of alliance; the free cities kept their freedom; elsewhere the land paid to the Roman people, according to the law of Hieron, the tithe which it had paid to Hieron. But, as the tithe was let out to *publicani,* oppression was easy. The praetor, after the occupation of Syracuse, dwelt there in the palace of Hieron as in the capital of the island. But, as a survival of the earlier state of things, one of his two quaestors was quartered at Eryx, the other being in attendance on himself. Under the supreme dominion of Rome even the unprivileged cities kept their own laws, magistrates and assemblies, provision being made for suits between Romans and Sicilians and between Sicilians of different cities.

Sicily was the first land to be tilled by slave-gangs, on the estates both of rich natives and of Roman settlers. It became the granary of Rome and the free population naturally degenerated and died out. The slaves were most harshly treated, and even encouraged by their masters to rob. The land was full of disorder, and the praetors shrank from enforcing the law against offenders, many of whom, as Roman knights, might be their own judges. Of these causes came the two great slave-revolts of the second half of the 2nd century B.C. The first lasted from 136 to 132, the time of Tiberius Gracchus and the fall of Numantia. Enna and Tauromenium were the headquarters of the revolt. The second lasted from 104 to 99, the time of the Cimbrian invasion.

Pirates troubled the coast, and all other evils were outdone by the three years' government of Verres (73–71 B.C.). Verres plundered and impoverished everywhere, removing anything of value, especially works of art, that took his fancy, and there is hardly a city that had not to complain of what it suffered at his hands. Another blow was the occupation of Messana by Sextus Pompeius in 43 B.C. He was master of Sicily for seven years, and during this period the corn supply of Rome was seriously affected. Augustus planted Roman colonies at Palermo, Syracuse, Tauromenium, Thermae, Tyndaris and Catana, but, as elsewhere, Latin in no way displaced Greek; it was simply set up alongside of it for certain purposes. In the division of provinces between Augustus and the senate, Sicily fell to the latter. Under the empire it had practically no history. Christianity was not introduced until after the middle of the 1st century A.D. Few emperors visited Sicily; Hadrian was there, as everywhere, in A.D. 126, and ascended Etna. Septimius Severus was proconsul of Sicily before he became emperor, probably in 189. In the division of Constantine, when the word "province" had lost its meaning, when Italy itself was mapped out into provinces, Sicily became one of these last. Along with Africa, Raetia and western Illyricum, it became part of the Italian praefecture; along with the islands of Sardinia and Corsica, it became part of the Italian diocese.

The earlier stages of Teutonic advance in the empire did not touch Sicily. Alaric thought of a Sicilian expedition, but a storm hindered him. Sicily was reached by the Vandals from Carthage; Gaiseric (440) subdued the great island for which Roman and Phoenician had striven, and his capture of Sicily was not a piratical incursion, but part of a larger design. But eventually (476) he made a treaty with Odoacer and gave up the island on condition of a tribute, which was never paid by Theodoric. Sicily was (from 491) ruled by a Gothic count and the Goths claimed to have treated the land with special tenderness. Theodoric gave Lilybaeum to the Vandal king Thrasamund as the dowry of his sister Analafrida, but it had returned to the possession of the Goths when Belisarius, conqueror of Africa, demanded it in vain as part of the Vandal possessions as a pretext for declaring war (533). In the Gothic war Sicily was the first land to be recovered for the empire, and that with the good will of its people (535). Panormus alone was stoutly defended by its Gothic garrison. In 550 Totila took some fortresses, but the Goths were driven out the next year.

See E. A. Freeman, *History of Sicily* (1891–94); Pauly-Wissowa, *Realencyclopädie, s.v.* Σικελια for the ancient geography, history, etc. of the island (bibl.); B. Pace, "Arti ed artisti della Sicilia antica" (1922) (*Memorie dei Lincei* 5. xv. 469 *sqq.*) for a survey of the ancient art; and B. Pace, "I Barbari e i Bizantini in Sicilia" (from *Archivio Storico Siciliano,* vols. xxxv., xxxvi.) (Palermo, 1911), for the 5th–9th

centuries after Christ. The very numerous rock cut churches, catacombs and habitations of this period are characteristic.

(E. A. F.; T. A.)

Sicily Under the Eastern Empire.—Sicily was thus won back to the Roman dominion. For 430 years some part of Sicily, for 282 years the whole of it, again remained a Roman province. In the later mapping out of the empire into purely military divisions, the *theme* (θέμα) of Sicily took in both the island and the nearest peninsula of the mainland, the oldest Italy. The island itself was divided for financial purposes into Syracuse and Lilybaeum. The Lombard and Frankish masters of the peninsula never fixed themselves in the island. When the Frank took the imperial crown of the West, Sicily still kept its allegiance to the Augustus at Constantinople, but was torn from the empire by the next race of conquerors.

Ecclesiastical Relations with Italy.—This connection of Sicily with the eastern division of the empire no doubt largely helped to keep up Greek life in the island. Still the connection with Italy was close, especially the ecclesiastical connection. The great source of our knowledge of Sicily in the century which followed the reconquest by Belisarius is the *Letters* of Pope Gregory the Great. Gregory's *Letters* are largely occupied with the affairs of the great Sicilian estates held by the Roman Church, as by the churches of Milan and Ravenna, but they also illustrate the general condition of the island. We hear of Manichaeans; Jews were plentiful, and Gregory causes compensation to be made for the unlawful destruction of synagogues. Of paganism we find no trace, save that pagan slaves were held by Jews. Sicily belonged to the Latin patriarchate; but we already see glimmerings of the coming disputes between the Eastern and Western Churches.

Early Saracen Inroads.—In the 9th, 10th and 11th centuries the old drama of Sicily was acted again. The island was again disputed between Europe and Africa. Panormus and Syracuse were again the headquarters of races and creeds, of creeds even more than of races. The older religious differences were small compared with the strife for life and death between Christendom and Islam. Gregory and Mohammed were contemporaries, and, though Saracen occupation did not begin in Sicily till more than two centuries after Gregory's death, Saracen inroads began much sooner. In 655 part of Sicily was plundered, and its inhabitants carried to Damascus. Then came the strange episode of the visit of Constans II. (641–668), the first emperor, it would seem, who had set foot in Sicily since Julian. After a war with the Lombards, after 12 days' plunder of Rome, he came on to Syracuse, where he was murdered in 668. Sicily now saw for the first time the setting up of a tyrant in the later sense. Mezetius, commander of the Eastern army of Constans, revolted, but Sicily and Roman Italy kept their allegiance to the new emperor, Constantine Pogonatus, who came in person to destroy him. Then came another Saracen inroad from Alexandria, in which Syracuse was sacked. Towards the end of the 8th century, though Sicily itself was untouched, its patricians and their forces play a part in the affairs of southern Italy as enemies of the Frankish power. Charlemagne himself was believed to have designs on Sicily; but, when it came to Saracen invasion, the sympathies of both pope and Caesar lay with the invaded Christian land.

Saracen Conquest.—In 813 a peace for ten years was made between the Saracens and the patrician Gregory. A few years after it expired Saracen settlement in the island began. About this time Crete was seized by Spanish adventurers. But the first Saracen settlers in Sicily were the African neighbours of Sicily, and they were called to the work by treason within the island. The second Semitic conquest of Sicily began in 827 at Mazzara on the old border of Greek and Phoenician. The advance of the invaders was slow. In two years all that was done was to occupy Mazzara and Mineum, and seemingly to destroy Agrigentum, well used to destruction. Attacks on Syracuse failed; so did attacks on Henna—*Castrum Ennae,* now changing into *Castrum Johannis,* Castrogiovanni. The actual gain was small; but the invaders took seizin alike of the coast and of the island.

A far greater conquest followed when new invaders came from Spain. In 831 Panormus passed away for ever from Roman, for 230 years from Christian, rule. Syracuse was for 50 years, not only, as of old, the bulwark of Europe, but the bulwark of Christendom. By the conquest of Panormus the Saracens were firmly rooted in the island. It became the seat of the amir or lord of Sicily. For a time, the Saracen advance was hindered by dissensions between the African and the Spanish settlers. In the end the Muslim conquests in Sicily became an Aghlabite principality owning at best a formal superiority in the princes of Kairawān. With the Saracen occupation begins a new division of the island, which becomes convenient in tracing the progress of Saracen conquest. This is into three valleys, known in later forms of language as Val di Mazzara or Mazza in the N.W., Val di Noto in the S.E. and Val Demone in the N.E. The first Saracen settlement of Val di Mazzara answers roughly to the old Carthaginian possessions. From Panormus the amir or lord of Sicily, Mohammed ibn Abdallah, sent forth his plunderers throughout Sicily and even into southern Italy. There, however, they made no lasting settlements.

The chief work of the next ten years was the conquest of the Val di Noto, but the first great advance was made elsewhere. In 843 the Saracens won the Mamertine city, Messina, and thus stood in the path between Italy and Sicily. At last, in 859, the very centre of the island, the stronghold of Henna, was taken, and the main part of Val di Noto followed. But the divisions among the Muslims helped the Christians; they won back several towns, and beat off all attacks on Syracuse and Tauromenium. It is strange that the reign of Basil the Macedonian (867), a time of such renewed vigour in the empire, was the time of the greatest of all losses in Sicily. In Italy the imperial frontier largely advanced; in Sicily imperial fleets threatened Panormus. But in 875 the accession of Ibrāhīm ibn Ahmad in Africa changed the face of things. The amir in Sicily, Ja'far ibn Ahmad, received strict orders to act vigorously against the eastern towns. In 877 began the only successful Semitic siege of Syracuse. The next year the city passed for the first time under the yoke of strangers to the fellowship of Europe.

Thus in 51 years the imperial and Christian territory in Sicily was cut down to a few points on or near the eastern coast, to the Val Demone in short without Messina. But between Muslim dissension and Christian valour the struggle had still to be waged for 87 years. Henna had been the chief centre of Christian resistance a generation earlier; its place was now taken by the small fort of Rametta not far from Messina. The Muslims of Sicily were busy in civil wars. In 900 Panormus had to be won by a son of Ibrāhīm from Muslim rebels provoked by his father's cruelty. But when Ibrāhīm himself came into Sicily, renewed efforts against the Christians led to the first taking of Tauromenium (908), of Rametta and of other points. The civil war that followed his death, the endless revolutions of Agrigentum hindered any real Saracen occupation of eastern Sicily. The emperors never gave up their claims to Sicily or their hopes of recovering it. Besides the struggle with the Christians in the island, there was often direct warfare between the empire and the Saracens; but such warfare was more active in Italy than in Sicily. In 956 a peace or truce was made by the emperor Constantine Porphyrogenitus. A few years later, Otto the Great, the restorer of the Western empire, looked to Sicily as a land to be won back for Christendom. In 963 Tauromenium was taken, and became for 100 years a Mohammedan possession. Rametta was the last stronghold to fall (965).

Reconquest by Eastern Empire.—Thus in 138 years the Arab did what the Canaanite had never done. The whole island was a Semitic, that is a Mohammedan, possession. But its first and longest period lasted only 73 years. In 1038, George Maniaces, the first captain of his time, was sent by the eastern emperor to win back the lost land. He too was helped by Saracen dissensions. The amir Abul-afar became a Roman vassal, and, like Alaric of old, became *magister militum* in the Roman army. His brother and rival, Abuhafas, brought help from Africa; and finally all joined against the Christians. Four years of Christian victory (1038–42) followed. In the host of Maniaces were men of all races. Town after town was delivered, first Messina,

then Syracuse, then a crowd of others. The exact extent of the reconquest is uncertain; Byzantine writers claim the deliverance of the whole island; but it is certain that the Saracens never lost Panormus. But court influence spoiled everything: Maniaces was recalled; under his successor Stephen, brother-in-law of the emperor Michael, the Saracens won back what they had lost. Messina alone held out, for how long a time is uncertain. But a conqueror came who had no empresses to thwart him. In 1060 began the 30 years' work of the first Roger.

Sicily Under Saracen Rule.—Thus for 263 years the Christian people of some part or other of Sicily were in subjection to Muslim masters. The land was won bit by bit. One town was taken by storm; another submitted on terms harsher or more favourable. The condition of the Christians varied from that of personal slaves to that of communities left free on the payment of tribute. The great mass were in the intermediate state usual among the non-Mohammedan subjects of a Mohammedan power. While the conquest was going on, the towns that remained unconquered gained in point of local freedom. They became allies rather than subjects of the distant emperor. So did the tributary districts, as long as the original terms were kept. But, as ever, the condition of the subject race grew worse. After the complete conquest of the island, while the mere slaves had turned Mohammedans, there is nothing more heard of tributary districts. Still, Christianity and the Greek tongue never died out; churches and monasteries received and held property; there still are saints and scholars. It would be rash to deny that traces of other dialects may not have lingered on; but Greek and Arabic were the two written tongues of Sicily when the Normans came. The Sicilian Saracens were hindered by their internal feuds from ever becoming a great power; but they stood high among Mohammedan nations. Their advance in civilization is shown by their position under the Normans, and above all by their admirable style of architecture. (*See* PALERMO.) They had a literature which Norman kings studied and promoted. The Normans, in short, came into the inheritance of the two most civilized nations of the time, and allowed them to flourish side by side.

Norman Conquest.—The most brilliant time for Sicily as a power in the world begins with the coming of the Normans. Never before or after was the island so united or so independent. Some of the old tyrants had ruled out of Sicily; none had ruled over all Sicily. The Normans held all Sicily as the centre of a dominion which stretched far beyond it. The conquest was the work of one man, Count Roger of the house of Hauteville. (*See* ROGER I.) The conquests of the Normans in Italy and Sicily form part of one enterprise; but they altogether differ in character. In Italy they overthrew the Byzantine dominion; their own rule was perhaps not worse, but they were not deliverers. In Sicily they were welcomed by the Christians as deliverers from infidel bondage.

As in the Saracen conquest of Sicily, as in the Byzantine recovery, so in the Norman conquest, the immediate occasion was given by a home traitor. Count Roger had already made a plundering attack, when Becumen of Catania, driven out by his brother, urged him to serious invasion. Messina was taken in 1060, and became for a while the Norman capital. The Christians everywhere welcomed the conqueror. But at Troina they presently changed their minds, and joined with the Saracens to besiege the count in their citadel. At Catania Becumen was set up again as Roger's vassal, and he did good service till he was killed. Roger soon began to fix his eye on the Saracen capital. But Palermo was not taken until 1071, and then only by the help of Duke Robert, who kept the prize to himself. Still its capture was the turning-point in the struggle. Taormina (Tauromenium) was won in 1078. Syracuse, under its amir, Benarvet, held out stoutly. He retook Catania by the help of a Saracen to whom Roger had trusted the city, and whom he himself punished. Catania was won back by the count's son Jordan. But progress was delayed by Jordan's rebellion and by the absence of Roger in his brother's wars. In 1085 Syracuse was won. Next year followed Girgenti and Castrogiovanni, whose chief became a Christian. Noto held out till 1090. Then the whole island was won, and Roger completed his conquest by a successful expedition to Malta.

Saracens Under Norman Rule.—The condition of the Saracens under the Normans differed in different places according to the circumstances of conquest. The Mohammedan religion was everywhere tolerated, in many places much more. But it would seem that, just as under the Muslim rule, conversions from Christianity to Islam were forbidden. On the other hand, conversions from Islam to Christianity were not always encouraged; Saracen troops were employed from the beginning, and Count Roger seems to have thought them more trustworthy when unconverted. At Palermo the capitulation secured to the Saracens the full enjoyment of their own laws; Girgenti was long mainly Saracen; in Val di Noto the Saracens kept towns and castles of their own. The ecclesiastical relations between Greeks and Latins are harder to trace. At the taking of Palermo the Greek bishop was restored; but his successors were Latins, and Latin prelates were placed in the bishoprics which Count Roger founded. Urban II. visited Sicily to promote the union of the Church, and he granted to the count those special ecclesiastical powers held by the counts and kings of Sicily as hereditary legates of the Holy See which grew into the famous Sicilian monarchy. But Greek worship went on; at Messina it lingered till the 15th century, and it has been since brought back by the Albanian colonists. But the Greeks of Sicily have long been united Greeks, admitting the authority of the see of Rome.

Linguistic Elements in Sicily.—In its results the Norman conquest of Sicily was a Latin conquest far more thorough than that which had been made by the Roman commonwealth. The Norman princes protected all the races, creeds and tongues of the island, Greek, Saracen and Jew. But new races came to settle alongside of them, all of whom were Latin as far as their official speech was concerned. The Normans brought the French tongue with them; it remained the court speech during the 12th century, and Sicily was thrown open to all speakers of French, many of whom came from England. There was constant intercourse between the two great islands, both ruled by Norman kings, and many natives of England filled high places in Sicily. But French was only a language of society, not of business or literature. The languages of inscriptions and documents are Greek, Arabic and Latin, in private writings sometimes Hebrew. The kings understood Greek and Arabic, and their deeds and works were commemorated in both tongues. Hence comes the fact, at first sight so strange, that Greek, Arabic and French have all given way to a dialect of Italian. But the cause is not far to seek. The Norman conquest opened Sicily to settlers from Italy, above all from the Norman possessions in Italy. Under the name of Lombards, they became an important, in some parts a dominant, element. Thus at Messina, where we hear nothing of Saracens, we hear much of the disputes between Greeks and Lombards. The Lombards had hardly a distinct language to bring with them. At the time of the conquest, French had already become a distinct speech from Latin; Italian hardly was such. The Lombard element, during the Norman reign, shows itself, not in whole documents or inscriptions, but in occasional words and forms, as in some of the mosaics at Monreale. And, if any element, Latin or akin to Latin, had lingered on through Byzantine and Saracen rule, it would of course be attracted to the new Latin element, and would help to strengthen it. It was this Lombard element that had the future before it. Greek and Arabic were antiquated, or at least isolated, in a land which Norman conquest had made part of western Europe and Latin Christendom. Even the French element was in some sort isolated, and later events made it more so. But the Lombard element was constantly strengthened by settlement from outside. Thus, in the face of Italian, both Greek and Arabic died out. Step by step, Christian Sicily became Latin in speech and in worship. But this was not till the Norman reigns were over. Till the end of the 12th century Sicily was the one land where men of divers creeds and tongues could live side by side.

Hence came both the short-lived brilliancy of Sicily and its later decay. In Sicily there were many nations all protected by the Sicilian king; but there was no Sicilian nation. Greek, Saracen,

Norman, Lombard and Jew could not be fused into one people; it was the boast of Sicily that each kept his laws and tongue undisturbed. Such a state of things could live on only under an enlightened despotism; the discordant elements could not join to work out really free and national institutions. Sicily had parliaments, and some constitutional principles were well understood. But they were assemblies of barons, or at most of barons and citizens; they could only have represented the Latin elements, Norman and Lombard, in the island. The elder races, Greek and Saracen, stand outside the relations between the Latin king and his Latin subjects. Still, as long as Greek and Saracen were protected and favoured, so long was Sicily the most brilliant of European kingdoms. But its greatness had no groundwork of national life; for lack of it the most brilliant of kingdoms presently sank below the level of other lands.

Roger I.—Four generations only span the time from the birth of Count Roger, about 1030, to the death of the emperor Frederick II. in 1250. Roger, great count of Sicily, was, at his death in 1101, succeeded by his young son Simon, and he in 1105 by the second Roger, the first king. He inherited all Sicily, save half Palermo—the other half had been given up—and part of Calabria. The rest of Palermo was soon granted; the Semitic capital became the abiding head of Sicily. On the death of his cousin, Duke William of Apulia, Roger gradually founded (1127–40) a great Italian dominion. To the Apulian duchy he added (1136) the Norman principality of Capua, Naples (1138), the last dependency of the Eastern empire in Italy, and (1140) the Abruzzi, an undoubted land of the Western empire. He thus formed a dominion which has been divided, united and handed over from one prince to another oftener than any other State in Europe, but whose frontier has hardly changed at all. In 1130 Roger was crowned at Palermo, by authority of the anti-pope Anacletus, taking the strange title of "king of Sicily and Italy." This, on his reconciliation with Pope Innocent II., he exchanged for "king of Sicily and of the duchy of Apulia and of the principality of Capua." By virtue of the old relations between the popes and the Normans of Apulia, he held his kingdom in fief of the Holy See, a position which on the whole strengthened the royal power. But his power, like that of Dionysius and Agathocles, was felt in more distant regions. His admiral, George of Antioch, Greek by birth and creed, warred against the Eastern empire, won Corfu for a season, and carried off the silk-workers from Thebes and Peloponnesus to Sicily. But Manuel Comnenus ruled in the East, and, if Roger threatened Constantinople, Manuel threatened Sicily. In Africa the work of Agathocles was more than renewed; Mahdia and other points were won and kept as long as Roger lived. These exploits won him the name of the "terror of Greeks and Saracens." To the Greeks, and still more to the Saracens, of his own island he was a protector and something more. His love for mathematical science, geography, etc., in which the Arabs excelled, is noteworthy.

William I. and II.—Roger's son William, surnamed the Bad, was crowned in his father's lifetime in 1151. Roger died in 1154, and William's sole reign lasted till 1166. It was a time of domestic rebellions, chiefly against the king's unpopular ministers, and it is further marked by the loss of Roger's African conquests. After William the Bad came (1166–89) his son, William the Good. Unlike as were the two men in themselves, in their foreign policy they are hardly to be distinguished. The Bad William has a short quarrel with the pope; otherwise Bad and Good alike appear as zealous supporters of Alexander III. and as enemies of both empires. The Eastern warfare of William the Good is stained by the frightful sack of Thessalonica; it is marked also by the formation of an Eastern State under Sicilian supremacy (1186). Corfu with Durazzo, Cephalonia and Zante, was granted by William to his admiral, Margarito, with the strange title of king of the Epeirots. He founded a dynasty, though not of kings, in Cephalonia and Zante. Corfu and Durazzo were to be more closely connected with the Sicilian crown.

Tancred.—The brightest days of Sicily ended with William the Good. His marriage with Joanna, daughter of Henry of Anjou and England, was childless, and William tried to procure the succession of his aunt Constance and her husband, King Henry VI. of Germany, son of emperor Frederick I. But the prospect of German rule was unpopular, and on William's death the crown passed to Tancred, an illegitimate grandson of King Roger, who figures in English histories in the story of Richard I.'s crusade. In 1191 Henry, now emperor, asserted his claims; but, while Tancred lived, he did little, in Sicily nothing, to enforce them.

William III.—On the death of Tancred (1194) and the accession of his young son, William III., the emperor came and conquered Sicily and the Italian possessions, with an amount of cruelty which outdid any earlier war or revolution. First of four Western emperors who wore the Sicilian crown, Henry died in 1197, leaving the kingdom to his young son, Frederick, heir of the Norman kings through his mother.

The relations between the various races of the islands are most instructive. The strong rule of Roger kept all in order. He called himself the defender of Christians; others, on account of his favour to the Saracens, spoke of him as a pagan. He certainly encouraged Saracen art and literature in every shape. His court was full of eunuchs. Under William the Good the Saracens seem to be losing their position. Hitherto they had been keeping their own civilization alongside of others. By a general outbreak on the death of William the Good, the Saracens, especially those of Palermo, were driven to take shelter in the mountains, where they sank into a wild people. The Jews, too, begin to sink into bondmen.

Emperor Frederick II.—The Germans who helped Henry to win the Sicilian crown did not become a new element in the island, but only a source of confusion during the minority of his son. Frederick—presently to be the renowned emperor Frederick II., was crowned at Palermo in 1198; but the child, deprived of both parents, was held to be under the protection of his lord, Pope Innocent III. During his minority the land was torn in pieces by turbulent nobles, revolted Saracens, German captains seeking settlements, the maritime cities of Italy, and professed French deliverers. In 1210 the emperor Otto IV., who had overrun the continental dominions, threatened the island. In 1212, just when Frederick was reaching an age to be of use in his own kingdom, he was called away to dispute the crown of Germany and Rome with Otto. Eight years more of disorder followed; in 1220 the emperor-king came back. He brought the Saracens of the mountains back again to a life in plains and cities, and presently planted a colony of them on the mainland at Nocera, when they became his most trusty soldiers. His necessary absences from Sicily led to revolts. He came back in 1233 from his crusade to suppress a revolt of the eastern cities, which seem to have been aiming at republican independence. A Saracen revolt in 1243 is said to have been followed by a removal of the whole remnant to Nocera. Some, however, certainly stayed or came back; but their day was over.

Under Frederick the Italian or Lombard element finally prevailed in Sicily. Of all his kingdoms Sicily was the best-beloved. He spoke all its tongues; he protected, as far as circumstances would allow, all its races. The heretic alone was persecuted; he was the domestic rebel of the church; Saracen and Jew were entitled to the rights of foreigners. Yet Frederick, patron of Arabic learning, suspected even of Muslim belief, failed to check the decline of the Saracen element in Sicily. The Greek element had no such forces brought against it. It was still a chief tongue of the island, in which Frederick's laws were put forth as well as in Latin. But it was clearly a declining element. Greek and Saracen were both becoming survivals in an island which was but one of the many kingdoms of its king. The Italian element advanced at the cost of all others. Frederick chose it as the court speech of Sicily, and he made it the speech of a new-born literature. Sicily, strangely enough, became the cradle of Italian song.

Manfred.—Two emperors had now held the Sicilian crown. On Frederick's death, in 1250, the crown passed to his son Conrad, not emperor indeed, but king of the Romans. He was nominally succeeded by his son Conradin. The real ruler under both was Frederick's natural son, Manfred. In 1258, on a false rumour of the death of Conradin, Manfred was himself crowned king of

Palermo. He had to found the kingdom afresh. Pope Innocent IV. had crossed into Sicily, to take advantage of the general discontent. The cities, whose growing liberties had been checked by Frederick's legislation, strove for practical, if not formal, independence, sometimes for dominion over their fellows. Messina laid waste the lands of Taormina, because Taormina would not obey the bidding of Messina. Yet, among these and other elements of confusion, Manfred succeeded in setting up again the kingly power, first for his kinsmen and then for himself. His reign continued that of his father, so far as a mere king could continue the reign of such an emperor. The king of Sicily was the first potentate of Italy, and came nearer than any prince since Louis II. to the union of Italy under Italian rule. He sought dominion, too, beyond the Adriatic: Corfu, Durazzo, and a strip of the Albanian coast became Sicilian possessions as the dowry of Manfred's Greek wife. But papal enmity was too much for him. His overlord claimed to dispose of his crown, and hawked it about among the princes of the West.

Charles of Anjou.—More came of the grant of Urban IV. (1264) to Charles, count of Anjou, and through his wife sovereign count of Provence. Charles, crowned by the pope in 1266, marched to take possession of his lord's grant. Manfred was defeated and slain at Benevento. Sicily was now again a province. But a province Sicily had no mind to be. In the continental lands Charles founded a dynasty; the island he lost after 16 years. His rule was not merely the rule of a stranger king surrounded by stranger followers; the degradation of the island was aggravated by gross oppression, grosser than in the continental lands. The continental lands submitted, with a few slight efforts at resistance. The final result of the Angevin conquest of Sicily was its political separation from the mainland.

Sicilian feeling was first shown in the support given to the luckless expedition of Conradin in 1268. Frightful executions in the island followed his fall. The rights of the Swabian house were now held to pass to Peter, king of Aragon, husband of Manfred's daughter Constance. The connection with Spain, which has so deeply affected the whole later history of Sicily, now begins. Charles held the Greek possessions of Manfred and had designs both on Epeiros and on Constantinople. The emperor Michael Palaeologus and Peter of Aragon became allies against Charles; the famous John of Procida acted as an agent between them; the costs of Charles's eastern warfare caused great discontent. The actual outbreak of 1282, the famous Sicilian Vespers, was stirred up by the wrongs of the moment. It began a struggle which ended, after 20 years, in the establishment of an Aragonese dynasty in Sicily. (*See* VESPERS, SICILIAN.)

Thus the great island of the Mediterranean again became an independent power. And, as far as legislation could make it, Sicily became one of the freest countries in Europe. By the laws of king Frederick III. (*q.v.*) parliaments were to be regularly held, and without their consent the king could not make war, peace or alliance. But Sicily never rose to the greatness of its Greek or its Norman days, and its old character had passed away. Of Greeks and Saracens we now hear only as a degraded remnant, to be won over, if it may be, to the Western Church. The kingdom had no foreign possessions; yet the isle of Gerba, off the African coast, was held for a short time, and traces of the connection with Greece went on in various shapes. If the kings of Sicily on this side the Pharos kept Corfu down to 1386, those beyond the Pharos became, in 1311, overlords of Athens, when that duchy was seized by Catalan adventurers, disbanded after the wars of Sicily. In 1530 the Sicilian island of Malta became the shelter of the Knights of Saint John, driven by the Turk from Rhodes, and Sicily has received several colonies of Christian Albanians, who have replaced Greek and Arabic by yet another tongue. (*See* NAPLES, KINGDOM OF.) (E. A. F.; T. A.)

BIBLIOGRAPHY.—Many Christian catacombs and Byzantine rock-cut villages, churches and tombs have been explored of recent years. *See* the comprehensive work by the late J. Führer and V. Schultze, "Die altchristlichen Grabstätte Siziliens" (Berlin, 1907, *Jahrbuch des K.D. archäologischen Instituts, Ergänzungsheft* vii.); and several articles by P. Orsi in the *Notizie degli scavi,* and in *Byzantinische Zeitschrift* (1898, 1; 1899, 613); also M. Amari, *Storia dei Musulmani di Sicilia* (1854–72); F. Chalandon, *Histoire de la domination normande en Italie et en Sicile* (1907).

SICILY, BANK OF, a public utility, non-profit earning bank with its seat in Palermo. Its foundation dates back to 1850 when two banks, established in 1843, amalgamated as the *Banco Regio dei Reali Domini al di là del Faro* for the collection of revenue in Sicily (then part of the Kingdom of the Two Sicilies), for receiving deposits, and with the right to issue notes. In 1867, when Italy had become a United Kingdom, the Bank assumed its present name of *Banco di Sicilia* and was recognised as a Bank of Issue, a privilege it enjoyed until the unification of the note issue in the *Banca d'Italia* in 1926. The *Banco di Sicilia* performs all banking operations; it has an important Savings Bank and an agricultural credit department organized under the provisions of the Act of 1906. Since 1922 it has played a part of increasing importance in the economic life of the Island, organizing a special "Foundation for the cultural and economic progress of Sicily" endowed with a capital grant of 30 million lire, the "V. Emanuel III. Institute for land reclamation in Sicily" (capital 20 million lire), the "General Warehouse Association of Sicily" (cap. 12 million lire), and the "Association for promoting the Tourist Industry in Sicily." It has 61 branch banks in Italy; on Jan. 31, 1929 it had a capital of 425 million lire and held 682 million lire in deposits on current and savings account. In 1925 it established in New York City the *Banco di Sicilia Trust Co.* (cap. in 1927 $1,100,000) which acts as a deposit bank for Italian emigrants. In 1927 this Trust Co. organized, under the laws of the State of New York, a holding and investment company, the "Bansicilia Corporation." (IG. M.)

SICKERT, WALTER RICHARD (1860–), British painter and etcher, was born at Munich May 31, 1860, the son of the painter, Oswald Adalbert Sickert, a contributor to *Fliegende Blätter,* and grandson of Johannes Sickert of Altona, painter and lithographer. Sickert studied under Whistler in Chelsea, but in 1885, following the advice of Degas, began to paint from drawings instead of from nature. His subject pictures include "Mamma mia po'aretta" (1903), "Noctes Ambrosianae" (1906), "The Camden Town Murder" (1906), "Army and Navy" (1913), "Ennui" (1914), "Sinn Fein" (1915), "Pierrots on Brighton Beach at Night" (1915), "Baccarat at Dieppe" (1920) and "Supper at the Casino" (1920). He also produced some architectural paintings, including "Hotel Royal, Dieppe" (1900), "Lansdowne Crescent" (1917) and "Pulteney Bridge" (1918). He became a member of the Société du Salon d'Automne, the Society of Twelve and the International Society, a fellow of the Royal Society of Painters, Etchers and Engravers, and in 1928 was elected president of the Royal Society of British Artists. He was elected A.R.A. in 1924. As a teacher he exercised a strong influence over the younger British painters.

SICKINGEN, FRANZ VON (1481–1523), German knight, was born at Ebernburg near Worms on March 2, 1481. He fought for the emperor Maximilian I. against Venice in 1508, inherited large estates on the Rhine, and increased his wealth and reputation by numerous feuds. In 1513 he took up the quarrel of Balthasar Schlör, a citizen who had been driven out of Worms, and attacked this city with 7,000 men. He made war upon Antony, duke of Lorraine, and compelled Philip, landgrave of Hesse, to pay him 35,000 gulden. In 1518 he interfered in a civil conflict in Metz, ostensibly siding with the citizens against the governing oligarchy. He led an army of 20,000 men against the city, compelled the magistrates to give him 20,000 gold gulden and a month's pay for his troops. In 1518 Maximilian released him from the ban, and he took part in the war carried on by the Swabian League against Ulrich I., duke of Württemberg. In the contest for the imperial throne upon the death of Maximilian in 1519, Sickingen accepted bribes from Francis I., king of France, but when the election took place he led his troops to Frankfort, where their presence assisted to secure the election of Charles V. For this service he was made imperial chamberlain and councillor, and in 1521 he led an expedition into France, which ravaged Picardy, but was beaten back from Mezières and forced to retreat. About 1517 Sickingen became intimate with Ulrich von Hutten,

and gave his support to Hutten's schemes. In 1519 a threat from him freed John Reuchlin from his enemies, the Dominicans, and his castles became in Hutten's words *a refuge for righteousness.* Here many of the reformers found shelter, and a retreat was offered to Martin Luther. After the failure of the French expedition, Sickingen, aided by Hutten, formed, or revived, a scheme to overthrow the spiritual princes and to elevate the order of knighthood. He declared war against his old enemy, Richard of Greiffenklau, archbishop of Trier, and marched against that city. Trier was loyal to the archbishop, and the landgrave of Hesse and Louis V., count palatine of the Rhine, hastened to his assistance. Sickingen fell back on his castle of Landstuhl, near Kaiserslautern, collecting much booty on the way. On Oct. 22, 1522 the council of regency placed him under the ban, to which he replied, in the spring of 1523, by plundering Kaiserslautern. The rulers of Trier, Hesse and the Palatinate decided to press the campaign against him, and having obtained help from the Swabian League, marched on Landstuhl. On May 6, 1523 he was forced to capitulate, and died the next day. He was buried at Landstuhl, and in 1889 a splendid monument was raised at Ebernburg to his memory and to that of Hutten.

Prutz, "Franz von Sickingen" in *Der neue Plutarch* (Leipzig, 1880), and the "Flersheimer Chronik" in Hutten's *Deutsche Schriften,* edited by O. Waltz and Szamatolati (Strassburg, 1891).

SICKLE: *see* REAPING.

SICKLES, DANIEL EDGAR (1825–1914), American soldier and diplomatist, was born in New York city on Oct. 20, 1825. He learned the printer's trade, studied in the University of the City of New York (now New York university), and was admitted to the bar in 1846. In 1853 he became corporation counsel of New York city, and from 1857 to 1861 was a Democratic representative in Congress. At the outbreak of the Civil War, Sickles was active in raising United States Volunteers in New York, became a brigadier-general of volunteers in Sept. 1861, led a brigade of the Army of the Potomac with credit up to the battle of Antietam, and then succeeded to a divisional command. He took part with distinction in the battle of Fredericksburg, and in 1863 as a major-general commanded the III. Army Corps. His energy and ability were conspicuous in the disastrous battle of Chancellorsville (*q.v.*); and at Gettysburg (*q.v.*) the part played by his corps in the desperate fighting around the Peach orchard was one of the most noteworthy incidents in the battle. He himself lost a leg and his active military career came to an end. Sickles was one of the few successful volunteer generals who served on either side. In 1869 he was retired with the rank of major-general (U.S.A.). He was minister to Spain from 1869 to 1873, and took part in the negotiations growing out of the "Virginius affair." (*See* SANTIAGO, CUBA.) In 1893–95 he was again a representative in Congress. His last years were disturbed by financial difficulties. He died in New York city on May 3, 1914.

SICULI, ancient Sicilian tribe (Gr. *Sikelói*). In historical times it occupied the eastern half of the island to which it gave its name. It plays a large though rather shadowy part in the early traditions of pre-Roman Italy. There is abundant evidence that the Siculi once lived in Central Italy east and even north of Rome (*e.g.* Servius *ad Aen.* vii. 795; Dion. Hal. i. 9. 22; Thucydides vi. 2). Thence they were dislodged by the Umbro-Safine tribes, and finally crossed to Sicily. They were distinct from the Sicani (*q.v.*; Virg. *Aen.* viii. 328) who inhabited the western half of the island.

The towns of the Siculi were under independent rulers. They played an important part in the history of the island after the arrival of the Greeks (*see* SICILY). Their agricultural pursuits and the volcanic nature of the island made them worshippers of the gods of the nether world, and they have enriched mythology with some national figures. The most important of these were the Palici, protectors of agriculture and sailors, who had a lake and temple in the neighbourhood of the river Symaethus, the chief seat of the Siculi; Adranus, father of the Palici, a god akin to Hephaestus, in whose temple a fire was always kept burning; Hybla (or Hyblaea), after whom three towns were named, whose sanctuary was at Hybla Gereatis. The connexion of Demeter and Kore with Henna (the rape of Proserpine) and of Arethusa with Syracuse is due to Greek influence. Their chief towns were: Agyrium (*San Filippo d'Argirò*); Centuripa (or Centuripae; *Centorbi*); Henna (*Castrogiovanni,* a corruption of Castrum Hennae through the Arabic *Casr-janni*); Hybla, three in number, (*a*) Hybla Major, called Geleatis or Gereatis, on the river Symaethus, probably the Hybla famous for its honey, although according to others this was (*b*) Hybla Minor, on the east coast north of Syracuse, afterwards the site of the Dorian colony of Megara, (*c*) Hybla Heraea in the south of the island. For authorities *see* SICILY.

SICYON (or SECYON, the older local form), an ancient Greek city in northern Peloponnesus between Corinth and Achaea, on a low triangular plateau about 2 m. from the Corinthian Gulf, at the confluence of the Asopus and the Helisson. Between city and port lay a fertile plain with olive-groves and orchards. Its primitive name was Aegialeia "beach-town"; its original population Ionian; the myth and cult of Adrastus show early connection with Argos; and in the *Iliad* it is a dependency of Agamemnon. After the Dorian invasion it had the three Dorian tribes with an equally privileged tribe of Aigialeis (probably old Ionian) and a class of land-serfs (*κορυνηφόροι* or *κατωνακοφόροι*). For some centuries Sicyon remained subject to Argos, and acknowledged a certain suzerainty as late as 500 B.C. But virtual independence was established in the 7th century by anti-Dorian tyrants, known after their founder as the Orthagoridae, whose mild rule lasted longer than any other Greek tyranny (about 665–565 B.C.). The founder's grandson Cleisthenes held intercourse with many commercial centres of Greece and south Italy and gave his heiress in marriage to Megacles of Athens, whose son was the Athenian legislator of that name. Cleisthenes (*q.v.*) besides reforming the city's constitution and replacing Dorian cults by the worship of Dionysus, was chief instigator of the First Sacred War (590) in the interest of Delphi. After the fall of the tyranny, Cleisthenes' institutions survived till the end of the 6th century, when Dorian supremacy was re-established, and the city joined the Peloponnesian League. Henceforth its policy was usually determined by Sparta or by its powerful neighbour Corinth. During the Persian wars Sicyon furnished 3,000 heavy-armed men; its school of bronze sculptors produced Canachus (*q.v.*) a master of the late archaic style. In the 5th century it suffered like Corinth from the commercial rivalry of Athens and was repeatedly harassed by Athenian ships. In the Peloponnesian war Sicyon followed Sparta and Corinth. Again in the Corinthian war Sicyon sided with Sparta. In 369 when it was captured and garrisoned by the Thebans a powerful citizen Euphron established himself tyrant by popular support. His deposition by the Thebans and subsequent murder freed Sicyon for a while, but new tyrants arose with the help of Philip II. of Macedon. Nevertheless during this period Sicyon reached its zenith as a centre of art: its school of painting under Eupompus attracted Pamphilus and Apelles as students; its sculpture culminated in Lysippus and his pupils. After participating in the Lamian war and the campaigns of the Macedonian pretenders the city was captured (303) by Demetrius Poliorcetes, who transplanted the inhabitants to the Acropolis and renamed the site Demetrias. In the 3rd century it passed from tyrant to tyrant, until in 251 it was liberated and enrolled in the Achaean League (*q.v.*). The destruction of Corinth (146) brought an acquisition of territory and presidency over the Isthmian games; yet in Cicero's time Sicyon had fallen deep into debt. Under the empire it was quite obscured by the restored Corinth and Patrae; Pausanias (A.D. 150) found it almost desolate. In Byzantine times it became a bishop's seat, and its later name "Hellas" reveals it as a refuge for Greeks from Slavonic immigrants of the 8th century.

An insignificant village, Vasiliko, now occupies the site. Ancient fortifications are still visible, and remains of a theatre, a stadium, aqueducts and foundations of buildings.

SIDDONS, SARAH (1755–1831), English actress, the eldest of 12 children of Roger Kemble, was born in the "Shoulder of Mutton" public-house, Brecon, Wales, on July 5, 1755.

She became attached to William Siddons, whom she married at Trinity Church, Coventry, on Nov. 26, 1773. In 1774 she played Belvidera in Otway's *Venice Preserved* at Cheltenham, and moved to tears a party of "people of quality" who had come to scoff. Garrick then sent his deputy to see her as Calista in Rowe's *Fair Penitent*, the result being that she was engaged to appear at Drury Lane at a salary of £5 a week.

After a very successful engagement at Bath, beginning in 1778 and lasting five years, she again appeared at Drury Lane, when her acting as Isabella in Garrick's version of Southerne's *Fatal Marriage* (Oct. 10), was a triumph, only equalled in the history of the English stage by that of Garrick's first night at Drury Lane in 1741 and that of Edmund Kean's in 1814.

As Lady Macbeth, Mrs. Siddons found the highest and best scope for her gifts. It fitted her as no other character did, and as perhaps, it will never fit another actress. Her tall figure, brilliant beauty, expressive eyes and her dignity of demeanour heightened the tragedy of the part. After Lady Macbeth she played Desdemona, Rosalind and Ophelia, all with great success; in Queen Catherine—which she first played on the occasion of her brother John Kemble's spectacular revival of *Henry VIII.* in 1788—she discovered a part almost as well adapted to her peculiar powers as that of Lady Macbeth. As Volumnia in Kemble's version of *Coriolanus* she also secured a triumph. It was of course inevitable that comparisons should be made between her and her only peer Rachel, who undoubtedly excelled her in intensity and the portrayal of fierce passion, but Rachel was a less finished artist, and lacked Mrs. Siddons' dignity and pathos. Her last appearance was on June 9, 1819, as Lady Randolph in Home's *Douglas*, for the benefit of Mr. and Mrs. Charles Kemble.

In private life Mrs. Siddons enjoyed the friendship and respect of many of her most eminent contemporaries. Horace Walpole at first refused to join the fashionable chorus of her praise, but he was ultimately won over. Dr. Johnson wrote his name on the hem of her garment in the famous picture of the actress as the Tragic Muse by Reynolds (now in the Dulwich Gallery). Mrs. Siddons died in London on June 8, 1831, and was buried in Paddington churchyard.

In 1897 Sir Henry Irving unveiled at Paddington Green a marble statue of her by Chavalliaud, after the portrait by Reynolds. There is also a statue by Chantrey in Westminster Abbey. Portraits by Lawrence and Gainsborough are in the National Gallery, and a portrait ascribed to Gainsborough is in the Garrick Club, London, which also possesses two pictures of the actress as Lady Macbeth by G. H. Harlow.

See Thomas Campbell, *Life of Mrs. Siddons* (2 vols., 1834); P. H. Fitzgerald, *The Kembles* (3 vols., 1871); Frances Ann Kemble, *Records of a Girlhood* (3 vols., 1878); A. Maurois, *Portrait d'une actrice* (1927).

SIDE (mod. *Eski Adalia*), an ancient city on the Pamphylian coast about 12 m. E. of the mouth of the Eurymedon. Possessing a good harbour in the days of small craft, it was the most important place in Pamphylia. Alexander visited and occupied it, and there the Rhodian fleet defeated that of Antiochus the Great, and in the succeeding century the Cilician pirates established here their chief seat. An inscription shows it had many Jews in early Byzantine times. The great ruins cover a large promontory, fenced from the mainland by a ditch and wall which has been repaired in mediaeval times and is singularly perfect. Within this is a maze of structures out of which rises the colossal ruin of the theatre, built up on arches like a Roman amphitheatre.

See C. Lanckoronski, *Les Villes de la Pamphylie et de la Pisidie*, i. (1890).

SIDEBANDS, a term used in radio to denote frequencies on either side of the carrier frequency produced by the process of single frequency modulation (*q.v.*).

SIDEBOARD. Originally the sideboard was what its name implies—a side-table, to which the modern dinner-wagon very closely approximates. Then two- or three-tiered sideboards were in use in the Tudor period, and were perhaps the ancestors, or collaterals, of the court-cupboard, which in skeleton they much resembled. Early in the 18th century they began to be replaced by side-tables properly so called. In the beginning these tables were entirely of wood and comparatively slight, but before long it became the fashion to use a marble slab instead of a wooden top, which necessitated a somewhat more robust construction. Many of the sideboard tables of this period were exceedingly handsome, with cabriole legs, claw or claw and bill feet, friezes of acanthus, much gadrooning and mask pendants. Many such tables came from Chippendale's workshops, but although that great genius beautified the type he found, he had no influence upon the evolution of the sideboard. That evolution was brought about by the growth of domestic needs. Save upon its surface, the sideboard-table offered no accommodation; it usually lacked even a drawer. Even, however, in the period of Chippendale's zenith separate "bottle cisterns" and "lavatories" for the convenience of the butler in washing the silver as the meals proceeded were, no doubt, sometimes in use. By degrees it became customary to place a pedestal, which was really a cellarette or a plate-warmer, at each end of the sideboard-table. One of them would contain ice and accommodation for bottles; the other would be a cistern. Sometimes a single pedestal would be surmounted by a wooden vase lined with metal and filled with water, and fitted with a tap. To whom is due the brilliant inspiration of attaching the pedestals to the table and creating a single piece of furniture out of three components there is nothing to show with certainty. It is most probable that the credit is due to Shearer, who unquestionably did much for the improvement of the sideboard; Hepplewhite and the brothers Adam distinguished themselves in the same field but it was Sheraton who brought it to its full *floraison*. By the use of fine exotic woods, the deft employment of satin wood and other inlays, and by the addition of gracefully ornamented brass-work at the back, sometimes surmounted by candles to light up the silver, Sheraton produced effects of great elegance. But for sheer artistic excellence in the components of what presently became the sideboard, the Adams stand unrivalled; some of their inlay and brass mounts were almost equal to the first work of the great French school.

SIDERITE or CHALYBITE. A mineral consisting of carbonate of iron, $FeCO_3$ (48·2% of iron) and forming an important ore of iron (*spathic iron-ore*).

SIDEROSTAT, an instrument which, like the coelostat and heliostat (*q.v.*), reflects a portion of the sky in a fixed direction notwithstanding the diurnal motion of the heavens. The name is applied especially to the polar siderostat, a form of telescope in which the observer looks down the polar axis on to a mirror; by adjusting the mirror he can bring any part of the sky into the field of view without changing his own position.

SIDGWICK, HENRY (1838–1900), English philosopher, was born at Skipton in Yorkshire on May 31, 1838. He was educated at Rugby and at Trinity, Cambridge. In 1859 he was elected to a fellowship at Trinity, and soon afterwards appointed to a classical lectureship there. This post he held for ten years, but in 1869 exchanged his lectureship for one in moral philosophy. In that year he resigned his fellowship on religious grounds. He retained his lectureship, and in 1881 was elected an honorary fellow. In 1874 he published his *Method of Ethics* (6th ed. 1901, containing emendations written just before his death). In 1875 he was appointed praelector on moral and political philosophy at Trinity, in 1883 Knightbridge professor of moral philosophy, and in 1885, the religious test having been removed, his college once more elected him to a fellowship on the foundation. Sidgwick took an active part in the business of the university, and in many forms of social and philanthropic work. He was one of the founders and first president of the Society for Psychical Research, and was a member of the Metaphysical Society. He took a leading part in promoting the higher education of women. It was at his suggestion and with his help that Miss Clough

opened a house of residence for students; and when this had developed into Newnham college, and in 1880 the North hall was added, Sidgwick, who had in 1876 married Eleanor Mildred Balfour (sister of A. J. Balfour), went with his wife to live there for two years. He died on Aug. 28, 1900. On the death of Miss Clough, the first principal of Newnham, in 1892, Mrs. Sidgwick succeeded her and retained the position until 1910. In that year she retired and until 1919 was bursar of the college. In 1910 she became secretary of the Society for Psychical Research.

Sidgwick was deeply interested in psychical phenomena, but his energies were primarily devoted to the study of religion and philosophy. As early as 1862 he described himself as a theist. For the rest of his life, though he regarded Christianity as "indispensable and irreplaceable—looking at it from a sociological point of view," he found himself unable to return to it as a religion. In political economy he was a Utilitarian on the lines of Mill and Bentham.

His chief works are *Principles of Political Economy* (1883, 3rd ed. 1901); *Scope and Method of Economic Science* (1885); *Outlines of the History of Ethics* (1886, 5th ed. 1902), enlarged from his article ETHICS in the *Encyclopædia Britannica; Elements of Politics* (1891, 2nd ed. 1897), an attempt to supply an adequate treatise on the subject starting from the old lines of Bentham and Mill. The following were published posthumously: *Philosophy; its Scope and Relations* (1902); *Lectures on the Ethics of T. H. Green, Mr. Herbert Spencer and J. Martineau* (1902); *The Development of European Polity* (1903); *Miscellaneous Essays and Addresses* (1904); *Lectures on the Philosophy of Kant* (1905).

See a *Memoir* of Henry Sidgwick, written by his brother with the collaboration of his widow (1906).

SIDI-BEL-ABBÈS, chief town of an arrondissement in the department of Oran, Algeria, 48 m. by rail S. of Oran, 1,552 ft. above the sea, on the right bank of the Mekerra. The population is 43,148, of which 28,024 are Europeans (21,295 French or naturalised French, of whom the majority is of Spanish origin). The town is the headquarters of the 1er régiment of the Foreign Legion. It is encircled by a crenellated and bastioned wall with a fosse, and has four gates, named after Oran, Daia, Mascara and Tlemçen respectively. Starting from the gates, two broad streets, shaded by plane trees, traverse the town east to west and north to south, the latter dividing the civil from the military quarters.

See Léon Bastide, *Bel Abbès et son arrondissement* (Oran, 1881); Léon Adoue, *Histoire de Sidi-bel-Abbès* (1927).

SIDMOUTH, HENRY ADDINGTON, 1ST VISCOUNT (1757–1844), English statesman, son of Dr. Anthony Addington, was born on May 30, 1757. Educated at Winchester College and Brasenose College, Oxford, he was elected, by the favour of William Pitt, member of parliament for Devizes in 1784. By close attention to his parliamentary duties, he obtained a wide knowledge of the rules and procedure of the House of Commons, and this fact, together with his intimacy with Pitt and his general popularity, secured his election as Speaker in June 1789. Like his predecessors, Addington continued to be a partisan after his acceptance of this office, took part at times in debate when the house was in committee; and on one occasion his partiality allowed Pitt to disregard the authority of the chair. He enjoyed the confidence of George III., and in the royal interest tried to induce Pitt to withdraw his proposal for the removal of the disabilities suffered by Roman Catholics. Rather than give way on this question Pitt resigned office early in 1801, when Addington formed a government. The new prime minister had the loyal support of Pitt; and the conclusion of the treaty of Amiens in March 1802 made him popular in the country. But Pitt, dissatisfied with the ministry for ignoring the threatening attitude of Napoleon, and making no preparations for a renewal of the war, withdrew his support. Addington then took steps to strengthen the forces of the crown, and made unsuccessful overtures to Pitt that both should serve under a new prime minister, or, later, that he himself should serve under Pitt. When the struggle with France was renewed in May 1803, it became evident that as a war minister Addington was not a success; and when Pitt became openly hostile, the continued confidence of the king and of a majority in the House of Commons was not a sufficient counterpoise to the ministry's waning prestige. Although careful and industrious, Addington had no brilliant qualities, and his mediocrity afforded opportunity for attack by his enemies. He resigned office in April 1804, and became the leader of the party known as the "king's friends." Pitt, who now returned to office, was soon reconciled with his old friend; in January 1805 Addington was created Viscount Sidmouth, and became lord president of the council. He left the cabinet in July 1805. In February 1806 he became lord privy seal in the ministry of Fox and Grenville, but resigned early in 1807 when the government proposed to throw open commissions in the army and navy to Roman Catholics and Protestant dissenters; in 1812 he joined the cabinet of Spencer Perceval as lord president of the council, becoming home secretary when the ministry was reconstructed by the earl of Liverpool in the following June. The ten years during which he held this office coincided with much misery and unrest among the labouring classes, and the government policy, for which he was mainly responsible, was one of severe repression. In 1817 the Habeas Corpus Act was suspended, and Sidmouth issued a circular to the lords-lieutenant declaring that magistrates might apprehend and hold to bail persons accused on oath of seditious libels. For this step he was severely attacked in parliament, and was accused of fomenting rebellion by means of his spies. Although shaken by the acquittal of William Hone on a charge of libel the government was supported by parliament; and after the "Manchester massacre" in August 1819 the home secretary thanked the magistrates and soldiers for their share in quelling the riot. He was mainly responsible for the policy embodied in the "Six Acts" of 1819. In December 1821 Sidmouth resigned his office, but remained a member of the cabinet without official duties until 1824, when he resigned owing to his disapproval of the recognition of the independence of Buenos Aires. Subsequently he took very little part in public affairs; but true to his earlier principles he spoke against Catholic emancipation in April 1829, and voted against the Reform Bill in 1832. He died at Richmond Park on Feb. 15, 1844.

Lewis, *Essays on the Administrations of Great Britain* (London, 1864); Spencer Walpole, *History of England* (London, 1878–1886).

SIDMOUTH, a town and watering-place of Devonshire, England, on the River Sid and the English channel, 167¾ m. W. by S. of London, by a branch of the Southern railway. Pop. (1931) 6,126. The town is shut in by hills which end in the forelands of Salcombe and High Peak. The shore line curves away, beyond these, westward to the Start and eastward to Portland—both visible from Sidmouth beach. Tradition tells of an older town buried under the sea; and Roman coins and other remains have been washed up on the beach. Traces of an ancient camp exist on High Peak. In the 13th century Sidmouth was a borough governed by a port.

SIDNEY or (SYDNEY), **ALGERNON** (1622–1683), English politician, second son of Robert, 2nd earl of Leicester, and of Dorothy Percy, daughter of Henry, 9th earl of Northumberland, was born at Penshurst, Kent. As a boy he showed much talent, which was carefully trained under his father's eye. In 1632 with his elder brother Philip he accompanied his father on his mission as ambassador extraordinary to Christian IV. of Denmark. In May 1636 Sidney went with his father to Paris, where he became a general favourite, and from there to Rome. In Oct. 1641 he was given a troop in his father's regiment in Ireland, of which his brother, known as Lord Lisle, was in command. In Aug. 1643 the brothers returned to England. At Chester their horses were taken by the Royalists, whereupon they again put out to sea and landed at Liverpool. Here they were detained by the Parliamentary commissioners, and by them sent up to London for safe custody. From this time Sidney ardently attached himself to the Parliamentary cause. On May 10, 1644, he was made captain of horse in Manchester's army, under the Eastern Association. He was shortly afterwards made lieutenant-colonel, and charged

at the head of his regiment at Marston Moor (July 2), where he was wounded, and rescued with difficulty. In April 1645 he was given the command of a cavalry regiment in Cromwell's division of Fairfax's army, was appointed governor of Chichester on May 10, and in December was returned to parliament for Cardiff. In July 1646 he went to Ireland, where his brother was lord-lieutenant, and was made lieutenant-general of horse and governor of Dublin. He had hardly reached Ireland when he was recalled and stationed at Dover castle as governor. He was at this time acting with the Independents, and was nominated one of the commissioners for the trial of Charles I. But he took no part in the trial, and remained at Penshurst until the trial was over. He states that he opposed the proceedings on the grounds, "first, that the king could be tried by no court; second, that no man could be tried by that court." In 1651 he lost his governorship of Dover castle, and spent some months in Holland. In the autumn he became a member of the council of State, but he disapproved of Cromwell's assumption of the supreme power, and retired to Penshurst, and then to The Hague, where he became a close friend of De Witt.

Upon the restoration of the Long Parliament, in May 1659, Sidney again took his seat, and was placed on the council of State. He was now, as before, especially concerned with the foreign work of the council. In June he was appointed one of three commissioners to mediate for a peace between Denmark, supported by Holland, and Sweden. He was probably intended to watch the conduct of his colleague, Admiral Montagu (afterwards 1st earl of Sandwich), who was in command of the Baltic squadron. Upon the conclusion of the treaty he went to Stockholm as plenipotentiary; and in both capacities he behaved with resolution and address. Meanwhile the Restoration had taken place and Sidney, instead of returning to England, went to Copenhagen, and then to Hamburg to await the turn of events. He then travelled by way of Venice to Rome. His father sent him very little money. Five shillings a day, he says, served him and two men very well for meat, drink and firing in Rome. He devoted himself to the study of books, birds and trees, and speaks of his natural delight in solitude being largely increased. In 1663 he left Italy, passed through Switzerland, where he visited Ludlow, and came to Brussels in September, where his portrait was painted by van Egmondt; it is now at Penshurst. He had thoughts of joining the imperial service, and offered to transport from England a body of the old Commonwealth men; but this was refused by the English court. The enmity against him was so great that now, as on other occasions, attempts were made to assassinate him. On the breaking out of the Dutch war, Sidney, who was at The Hague, urged an invasion of England, and shortly afterwards went to Paris, where he offered to raise a rebellion in England on receipt of 100,000 crowns. Unable, however, to come to terms with the French Government, he once more went into retirement in 1666,—this time to the south of France. In Aug. 1670 he was again in Paris, and Arlington proposed that he should receive a pension from Louis; Charles II. agreed, but insisted that Sidney should return to Languedoc.

His father was now very ill, and after much difficulty Sidney obtained leave to come to England in the autumn of 1677. Lord Leicester died in November; and legal business connected with other portions of the succession detained Sidney from returning to France as he had intended. He soon became involved in political intrigue, joining, in general, the country party, and holding close communication with Barillon, the French ambassador. In the beginning of 1679 he stood for Guildford, and was warmly supported by William Penn, with whom he had long been intimate, and whom he is said (as is now thought, erroneously) to have helped in drawing up the constitution of Pennsylvania. He was defeated by court influence, and his petition to the House, complaining of an undue return, never came to a decision. His *Letters to Henry Savile*, written at this period, are of great interest. He was in Paris, apparently only for a short while, in Nov. 1679. Into the prosecution of the Popish Plot Sidney threw himself warmly, and was among those who looked to Monmouth, rather than to William, to take the place of James in the succession, though he afterwards disclaimed all interest in such a question. He now stood for Bramber (Sussex), again with Penn's support, and a double return was made. He is reported on Aug. 10, 1679, as being elected for Amersham (Buckingham) with Sir Roger Hill. When parliament met, however, in Oct. 1680, his election was declared void. But now, under the idea that an alliance between Charles and William would be more hostile to English liberty than would the progress of the French arms, he acted with Barillon in influencing members of parliament in this sense.

Upon the dissolution of the last of Charles's parliaments the king issued a justificatory declaration. This was at once answered by a paper entitled *A Just and Modest Vindication, etc.*, the first sketch of which is imputed to Sidney. It was then, too, that his most celebrated production, the *Discourses concerning Government*, was concluded, in which he upholds the doctrine of the mutual compact and traverses the High Tory positions.

For a long while Sidney kept himself aloof from the duke of Monmouth, to whom he was introduced by Lord Howard. After the death of Shaftesbury, however, in Nov. 1682, he entered into the conferences held between Monmouth, Russell, Essex, Hampden and others. That treasonable talk went on seems certain, but it is probable that matters went no further. The watchfulness of the court was, however, aroused, and on the discovery of the Rye House Plot, Sidney, who had always been regarded in a vague way as dangerous, was arrested while at dinner on June 26, 1683. His papers were carried off, and he was sent at once to the Tower on a charge of high treason. For a considerable while no evidence could be found on which to establish a charge. Jeffreys, however, was made lord chief-justice in September; a jury was packed; and, after consultations between the judge and the crown lawyers, Sidney was brought to listen to the indictment on Nov. 7.

The trial began on Nov. 21; Sidney was refused a copy of the indictment, in direct violation of law, and he was refused the assistance of counsel. Hearsay evidence and the testimony of the perjured informer Lord Howard, whom Sidney had been instrumental in introducing to his friends, were first produced. This being insufficient, partial extracts from papers found in Sidney's study, and supposed only to be in his handwriting, in which the lawfulness of resistance to oppression was upheld, were next relied on. He was indicted for "conspiring and compassing the death of the king." Sidney conducted his case throughout with skill. Against the determination to secure a conviction, however, his courage, eloquence, coolness and skill were of no avail, and the verdict of "guilty" was given. On Nov. 25, Sidney presented a petition to the king. The necessity, however, of checking the hopes of Monmouth's partisans caused the king to be inexorable. The last days of Sidney's life were spent in drawing up his *Apology* and in discourse with Independent ministers. He was beheaded on the morning of Dec. 7, 1683. His remains were buried at Penshurst.

An edition of the *Discourses concerning Government*, containing his letters, the report of his trial, and the "Apology" written in his last hours, was published in 1763, and reprinted in 1772, with corrections and additions. There is a notice of Algernon Sidney in the preface to Collins's *Sidney Papers*, and some letters of his appear in that collection. *See* also A. C. Ewald, *Life and Times of Algernon Sidney* (2 vols., 1873); and the life by C. H. Firth in the *Dictionary of National Biography*. (O. A.; X.)

SIDNEY, SIR HENRY (1529–1586), lord deputy of Ireland, was the eldest son of Sir William Sidney, a prominent politician and courtier in the reigns of Henry VIII. and Edward VI., from both of whom he received extensive grants of land, including the manor of Penshurst in Kent, which became the principal residence of the family. Henry was brought up at court as the companion of Prince Edward, afterwards King Edward VI.; and he continued to enjoy the favour of the sovereign throughout the reigns of Edward and Mary. In 1556 he went to Ireland with the lord deputy, the earl of Sussex, who in the previous year had married his sister Frances Sidney; and from the first he had a large share in the administration of the country, especially in the military measures taken by his brother-in-law for bringing the native Irish chieftains into submission to the English Crown.

In the course of the lord deputy's Ulster expedition in 1557 Sidney devastated the island of Rathlin; and during the absence of Sussex in England in the following year Sidney was charged with the sole responsibility for the government of Ireland, which he conducted with marked ability and success. A second absence of the lord deputy from Ireland, occasioned by the accession of Queen Elizabeth, threw the chief control into Sidney's hands at the outbreak of trouble with Shane O'Neill, and he displayed great skill in temporizing with that redoubtable chieftain till Sussex reluctantly returned to his duties in August 1559. About the same time Sidney resigned his office of vice-treasurer of Ireland on being appointed president of the Welsh Marches.

In 1565 Sidney was appointed lord deputy of Ireland in place of Sir Nicholas Arnold, who had succeeded the earl of Sussex in the previous year. He found the country in a more impoverished and more turbulent condition than when he left it, the chief disturbing factor being Shane O'Neill in Ulster. With difficulty he persuaded Elizabeth to sanction vigorous measures against O'Neill; and although the latter successfully avoided a decisive encounter, Sidney restored O'Neill's rival Calvagh O'Donnell to his rights, and established an English garrison at Derry which did something to maintain order. In 1567 Shane was murdered by the MacDonnells of Antrim (*see* O'NEILL), and Sidney was then free to turn his attention to the south, where with vigour and determination he arranged the quarrel between the earls of Desmond and Ormonde, and laid his hand heavily on other disturbers of the peace; then, returning to Ulster, he compelled Turlough Luineach O'Neill, Shane's successor in the clan chieftainship, to make submission, and placed garrisons at Belfast and Carrickfergus to overawe Tyrone and the Glynns. In the autumn of 1567 Sidney went to England, and was absent from Ireland for the next ten months. On his return he urged upon Cecil the necessity for measures to improve the economic condition of Ireland, to open up the country by the construction of roads and bridges, to replace the Ulster tribal institutions by a system of freehold land tenure, and to repress the ceaseless disorder prevalent in every part of the island. In pursuance of this policy Sidney dealt severely with the Butlers in Munster.

Sidney left Ireland in 1571, aggrieved by the slight appreciation of his statesmanship shown by the queen; but he returned thither in September 1575 with increased powers and renewed tokens of royal approval, to find matters in a worse state than before, especially in Antrim, where the MacQuillins of the Route and Sorley Boy MacDonnell (*q.v.*) were the chief fomenters of disorder. Having to some extent pacified this northern territory, Sidney repaired to the south, where he was equally successful in making his authority respected. He left his mark on the administrative areas of the island by making shire divisions on the English model. At an earlier period he had already in the north combined the districts of the Ardes and Clandeboye to form the county of Carrickfergus, and had converted the country of the O'Farrells into the county of Longford; he now carried out a similar policy in Connaught, where the ancient Irish district of Thomond became the county Clare, and the counties of Galway, Mayo, Sligo and Roscommon were also delimited. He suppressed a rebellion headed by the earl of Clanricarde and his sons in 1576, and hunted Rory O'More to his death two years later. Meantime Sidney's methods of taxation had caused discontent among the gentry of the Pale, who carried their grievances to Queen Elizabeth. Greatly to Sidney's chagrin the queen censured his extravagance, and notwithstanding his distinguished services to the crown he was recalled in September 1578, and was coldly received by Elizabeth. He lived chiefly at Ludlow Castle for the remainder of his life, performing his duties as president of the Welsh Marches, and died there on May 5, 1586.

O'Donovan's edition of *The Annals of Ireland by the Four Masters* (7 vols., Dublin, 1851); Holinshed's *Chronicles*, vol. iii. (6 vols., London, 1807); Richard Bagwell, *Ireland under the Tudors* (3 vols., London, 1885); *Calendar of Ancient Records of Dublin*, edited by Sir J. T. Gilbert, vols. i. and ii. (Dublin, 1889); Sir J. T. Gilbert, *History of the Viceroys of Ireland* (Dublin, 1865); J. A. Froude, *History of England* (12 vols., London, 1856–70).

SIDNEY, SIR PHILIP (1554–1586), English poet, statesman and soldier, eldest son of Sir Henry Sidney and his wife Mary Dudley, was born at Penshurst on Nov. 30, 1554. On Oct. 17, 1564, he was entered at Shrewsbury school, close to Ludlow Castle, his father's official residence as lord president of Wales. His life-long friend and first biographer, Fulke Greville, entered the school on the same day. In 1568 he went up to Christ Church, Oxford, where he formed friendships with Richard Hakluyt and William Camden. In 1572 Sidney received the Queen's leave to travel and learn foreign languages.

Travels.—He went first of all in the earl of Lincoln's suite to Paris, where he witnessed the St. Bartholomew massacre. From Paris he went to Frankfort-on-the-Main (1573), where he lodged with the printer Andrew Wechel, with whom also Herbert Languet was staying. Sidney had from his earliest youth an unwonted maturity of manner, which, combined with charm, gained him the confidence of men of affairs. In France he was in close connection with the Huguenot leaders, and Languet, an ardent Protestant, went on with him to Vienna. In October Sidney left for Italy; his letters to Languet afford considerable insight into the development of his character and ideas. Sidney stayed some time in Venice, and sat to Paolo Veronese for a portrait. In July 1574 he was seriously ill, and on his recovery returned to Vienna. He visited Poland with Languet, where he is said to have been offered the vacant crown, and then stayed at Vienna in a vaguely diplomatic capacity. He wrote a letter on the state of affairs to Burghley in Dec. 1574. The count moved to Prague in 1575, and from there he was summoned home.

At Court.—He found his sister Mary at court, and a patron in his uncle, Leicester. On one of the Queen's progresses he met Penelope Devereux, daughter of the Earl of Essex, then a child of twelve, who was later the "Stella" of his sonnets. Essex died the next year, and seems to have desired a match between Sidney and Penelope. A letter of 1576 even mentions a "treaty" between them. But nothing was done. In the spring of 1577 Sidney was sent to congratulate the new Elector Palatine and Emperor, and to promote generally the Protestant cause. He met Don John of Austria at Louvain, and went on to Heidelberg and Prague. He proposed a Protestant league and Church conference, and in a speech to the Emperor advocated a general league against Rome and Spain. On his way back he visited William of Orange. On his return home he paid the first of many visits to his sister Mary, who had married the Earl of Pembroke, at Wilton. Sidney now made it his business to defend his father's interests at Court, particularly from Lord Ormond, who was doing his best to prejudice the Queen against him. He drew up a detailed defence of his father's Irish government for presentation to the Queen. A rough draft of four sections is preserved in the British Museum (*Cotton MS., Titus B.*, xii., 557), which, even in its fragmentary state, justifies the estimate of it formed by Edward Waterhouse (*Sidney Papers*). At this time Sidney was beginning to be a figure in the world of letters; Spenser, whom he met in 1578, dedicated the *Shepherdes Calendar* to him the next year. He was a member of the Areopagus Society, which sought to introduce classical metres in English verse, and he wrote the Masque with which Leicester entertained the Queen at Wanstead in 1578, *The Lady of the May*. But Leicester's disgrace partially involved Sidney, and after a quarrel with Oxford, probably over the proposed Anjou marriage of the Queen, followed by more active opposition to the proposal in 1580 (Sidney Papers p. 287). Sidney had to leave the Court and returned to Wilton.

Stella.—Here Sidney began the *Arcadia* for his sister's amusement; not long afterwards he was allowed to return to Court. About this time must be placed the *Astrophel and Stella* sonnets. The date is not the only obscure point about them. His *Apologie for Poetrie* appeared about 1581 and he was knighted in 1583. That autumn he married Frances, daughter of Sir Francis Walsingham. He still desired active service, took a keen interest in the enterprises of Frobisher, Hakluyt and Raleigh, and was especially enthusiastic for the Protestant cause against Spain. He advocated a direct attack on Spain, and was himself preparing to sail with Drake in 1585 when the Queen recalled him. At last he was given

a command in the Netherlands, as governor of Flushing.

Active Service and Death.—In July 1586 he made a successful raid on Axel, near Flushing, and in September he joined the force of Sir John Norris, who was operating against Zutphen. On the 22nd he joined a small force sent out to intercept a convoy of provisions. During the fight that ensued he was struck in the thigh by a bullet. He succeeded in riding back to the camp. The often-told story that he refused a cup of water in favour of a dying soldier, with the words, "Thy need is greater than mine," is in keeping with his character. He owed his death to a quixotic impulse. Sir William Pelham happening to set out for the fight without greaves, Sidney also cast off his leg-armour, which would have defended him from the fatal wound. He died at Arnheim, on Oct. 17, 1586, and was buried at St. Paul's.

Sidney's death was a personal grief to people of all classes. Some two hundred elegies were produced in his honour. Of all these tributes the most famous is *Astrophel, A Pastoral Elegie,* added to Edmund Spenser's *Colin Clout's Come Home Again* (1595). Spenser wrote the opening poem; other contributors are Sidney's sister, the countess of Pembroke, Lodowick Bryskett and Matthew Roydon.

Writings.—Sidney's writings were not published during his lifetime. *A Worke concerning the trewnesse of the Christian Religion,* translated from the French of Du Plessis Mornay, was completed and published by Arthur Golding in 1587.

The Countesse of Pembroke's Arcadia written by Philippe Sidnei (1590), in quarto, is the earliest edition of Sidney's famous romance. A folio edition, issued in 1593, is stated to have been revised and rearranged by the countess of Pembroke, for whose delectation the romance was written. She was charged to destroy the work sheet by sheet as it was sent to her. The circumstances of its composition partly explain the difference between its intricate sentences, full of far-fetched conceits, repetition and antithesis, and the simple and dignified phrase of the *Apologie for Poetrie.* The style is a concession to the fashionable taste in literature which the countess may reasonably be supposed to have shared; but Sidney himself, although he was no friend to euphuism, was evidently indulging his own mood in this highly decorative prose.

Sonnets.—The series of sonnets to Stella were printed in 1591 as *Sir P.S.: His Astrophel and Stella,* by Thomas Newman, with an introductory epistle by T. Nash, and some sonnets by other writers. In 1598 the sonnets were reprinted in the folio edition of Sidney's works, entitled from its most considerable item *The Countesse of Pembroke's Arcadia,* edited by Lady Pembroke, with considerable additions. The songs are placed in their proper position among the sonnets, instead of being grouped at the end, and two of the most personal poems (possibly suppressed out of consideration for Lady Rich in the first instance), which afford the best key to the interpretation of the series, appear for the first time. Sidney's sonnets adhere more closely to French than to Italian models. The octave is generally fairly regular on two rhymes, but the sestet usually terminates with a couplet. The *Apologie for Poetrie* was one of the "additions" to the countess of Pembroke's *Arcadia* (1598), where it is entitled "The Defence of Poesie." It first appeared separately in 1594 (unique copy in the Rowfant Library, reprint 1904, Camb. Univ. Press). Sidney takes the word "poetry" in the wide sense of any imaginative work, and deals with its various divisions. Apart from the subject matter, which is interesting enough, the book has a great value for the simple, direct and musical prose in which it is written. *The Psalmes of David,* the paraphrase in which he collaborated with his sister, remained in MS. until 1823, when it was edited by S. W. Singer. A translation of part of the *Divine Sepmaine* of G. Salluste du Bartas is lost. There are two pastorals by Sidney in Davison's *Poetical Rhapsody* (1602).

Letters and Memorials of State . . . (1746) is the title of an invaluable collection of letters and documents relating to the Sidney family, transcribed from originals at Penshurst and elsewhere by Arthur Collins. Fulke Greville's *Life of the Renowned Sir Philip Sidney* (1652, ed. by Nowell Smith, 1907), is a panegyric dealing chiefly with his public policy. *The Correspondence of Sir Philip Sidney and Hubert Languet* was translated from the Latin and published with a memoir by Steuart A. Pears (1845). The best biography of Sidney is *A Memoir of Sir Philip Sidney* by H. R. Fox Bourne (1862). A revised life by the same author is included in the "Heroes of the Nations" series (1891). Critical appreciation is available in J. A. Symonds's *Sir Philip Sidney* (1886), in the "English Men of Letters" series; in J. J. A. Jusserand's *English Novel in the Time of Shakespeare* (1890); and in modern editions of Sidney's works, among which may be mentioned Mr. A. W. Pollard's edition (1888) of *Astrophel and Stella,* Professor Arber's reprint (1868) of *An Apologie for Poetrie,* and Mr. Sidney Lee's *Elizabethan Sonnets* (1904) in the re-issue of Professor Arber's *English Garner,* where the sources of Sidney's sonnets are fully discussed. *See* also a collection of *Sidneiana* printed for the Roxburghe Club in 1837, a notice by Mrs. Humphry Ward in Ward's *English Poets,* i. 341 *seq.,* and a dissertation by Dr. K. Brunhuber, *Sir Philip Sidney's Arcadia und ihre Nachläufer* (Nürnberg, 1903). A complete text of Sidney's prose and poetry, edited by Albert Feuillerat, is included in the Cambridge English Classics (1914–23).

SIDNEY, a city of western Ohio, U.S.A., the county seat of Shelby county; 40 m. N. of Dayton, on the Miami river and the Dixie highway. It is served by the Baltimore and Ohio, the Big Four and electric railways. Pop. (1920), 8,590 (96% native white); 1930, Federal census, 9,301. The city lies on an elevated table-land, in a rich agricultural region. It has a large tannery and various other manufacturing industries. Sidney was laid out in 1819 to be the county seat in place of Hardin (5 m. W.) where the first court had been held in May, and was named after Sir Philip Sidney. It was incorporated as a village in 1820, as a town in 1824 and as a city in 1897.

SIDON, once the principal city of Phoenicia, now the principal town of the southern district of Great Lebanon under the French mandate. Sidon is to-day a city of 10,000 inhabitants, the majority of whom are Muslims. Its houses are grouped round a castle dominating a promontory to the south of which was the ancient Egyptian harbour, now little more than a memory, and the modern harbour to the north half silted up. Around the town as far as the eye can see stretch gardens of orange trees, apricots, bananas and lemons—the fortune of Sidon.

History.—Older than Tyre and acknowledged as its mother, Sidon has had an eventful history. The Homeric poems laud the skill of its artisans. The Philistines destroyed its fleet and laid the city in ashes. Assyria and Babylonia coveted the wealth of her bazaars and a splendid succession of monarchs led armies against her to disturb her peace and loot her treasures. In the 7th century B.C. during a pause in Babylonian oppression Egypt intervened. The Persian yoke in due course supplanted the Babylonian and an injudicious revolt against Artaxerxes Ochus met with condign punishment. Unlike Tyre it submitted without resistance to Alexander the Great. The Seleucids of Syria, the Ptolemies of Egypt, and the Romans exercised lordship in turn. Herod the Great, as was his wont, embellished the town. Jesus visited its neighbourhood and St. Paul on his way to Rome was permitted to land to visit his friends and refresh himself. Sidon's bishop attended the Council of Nicea. To maintain its independence it leagued itself with the Crusaders (1107), and four years later Baldwin dealt faithfully with the city for bad faith. Saladin took and dismantled it after Hattin. The Franks were back again within it in 1197, only to see it relapse quickly into Muslim hands and be turned to ruins. The Franks rebuilt (1228), the Saracens redevastated (1249). King Louis restored it (1253); the Mongols ravaged it (1260). Once more assisted to rise by the Templars it was abandoned after the fall of Acre (1291). It blossomed into vigorous existence, in the 17th century under Fakhr ed-Dīn, the Druse emir, who encouraged and protected its commerce. Jezzār Pasha drove the French forth from its gates (1791). In 1840 it was bombarded by the allied fleets (Britain, Austria, Turkey), and British troops occupied it Oct. 6, 1918.

Archaeology.—A large necropolis was discovered south-east of the town in 1855, and yielded in the tomb chambers numerous sarcophagi and wall-paintings. The most important were the sarcophagi of two Sidonian kings, Eshmunazar (now in the Louvre), and Tabnith (in Constantinople). Both have valuable Phoenician inscriptions. A further discovery of 17 magnificent sarcophagi was made in 1887, including the famous "Alexander" sarcophagus. (*See* GREEK ART.) They are now in the museum at Constantinople. Recently a fresh archaeological survey and excavations

have been made in the Sidon area under French auspices.

See T. Macridy Bey, *Le Temple d' Echmoun à Sidon* (1904); G. Contenau, *Mission Archéologique à Sidon* (1914); C. C. Torrey, "A Phoenician Necropolis at Sidon": *Annual Amer. Sch. Or. Research Jerusalem* (1919-20); G. Contenau, *La Civilisation Phénicienne* (1926) 21 *seq.* (E. Ro.)

SIEBENGEBIRGE ("The Seven Hills"), a group of hills on the Rhine, 6 m. above Bonn. They are of volcanic origin. The district is a favourite tourist resort. The hills are as follows: Drachenfels (1,067 ft.) surmounted by the ruins of an old castle; immediately behind it, Wolkenburg (1,076 ft.); and to the north Petersberg (1,096 ft.), with a pilgrimage chapel; then, to the south, a chain of four—viz., Ölberg (1,522 ft.), the highest of the range; Löwenburg (1,506 ft.); Lohrberg (1,444 ft.), and, farthest away, Nonnenstromberg (1,107 ft.). At the foot of the Drachenfels, (north side) lies the little town of Königswinter, whence a mountain railway ascends to the summit, and a similar railway runs up the Petersberg. Ruins crown almost every hill.

SIEDLCE, a town of Poland in the province of Lublin, 56 m. E.S.E. of the city of Warsaw, on the Brest–Litewski railway. It is a Roman Catholic episcopal see. The Oginskis, to whom it belonged, have embellished it with a palace and gardens. Pop. (1921), 30,800, two-thirds Jews.

SIEGBURG, a town in the Prussian Rhine Province, on the river Sieg, 16 m. by rail S.E. of Cologne by the railway to Giessen. Pop. (1925) 18,614. The town, which was founded in the 11th century, attained the height of its prosperity in the 15th and 16th centuries owing to its pottery wares. Siegburg pitchers (*Siegburger Krüge*) were widely famed.

SIEGE, the "sitting down" of an army or military force before a fortified place for the purpose of taking it, either by direct military operations or by starving it into submission (*see* FORTIFICATION AND SIEGECRAFT).

SIEGEN, a town in the Prussian province of Westphalia, situated 63 m. E. of Cologne by rail, on the Sieg, a tributary entering the Rhine opposite Bonn. Pop. (1925) 30,951. Siegen was the capital of an early principality belonging to the house of Nassau. In 1815 the congress of Vienna assigned it to Prussia. The town contains two palaces of the former princes of Nassau-Siegen. The surrounding district, to which it gives its name, abounds in iron-mines, and iron founding and smelting are the most important branches of industry in and near the town. Rubens is said to have been born here in 1577.

SIEMENS, ALEXANDER (1847–1928), British electrical engineer, was born in Hanover on Jan. 22, 1847, and was educated at Berlin and Hanover. In 1867 he was employed by Siemens Brothers, Woolwich, for whom he helped to build the Indo-European telegraph line in Persia (1868), and to lay the Black sea cable in 1869. He served in the Prussian army during the Franco-Prussian War, afterwards returning to England to work for Sir William Siemens, in England, Canada and the United States. In 1878 he became a naturalized British subject, and in 1879 was appointed departmental manager in Siemens Brothers. He was associated with Sir William Siemens in the development of the regenerative furnace, and he developed a system of lighting public halls with arc lamps. His methods were put into practice in the reading room of the British Museum and in the Albert hall. Siemens was also responsible for the installation of electric light at Godalming, the first English town to be so lighted. He served as president of the Institution of Electrical Engineers and the Institution of Civil Engineers. He died Feb. 19, 1928.

SIEMENS, ERNST WERNER VON (1816–1892), German electrician, was born on Dec. 13, 1816, at Lenthe in Hanover. After attending the gymnasium at Lübeck, he entered the Prussian army as a volunteer, and for three years was a pupil in the military academy at Berlin. Between 1838 and 1848 he served in the artillery, and was entrusted with many specialized works such as the fortification of Eckernförde harbour and the laying of the first telegraph line in Germany, that between Berlin and Frankfort-on-Main. Thenceforward he devoted his energies to furthering the interests of the newly founded firm of Siemens and Halske, which under his guidance became one of the most important electrical undertakings in the world, with branches in different countries that gave it an international influence.

As his entrance into commercial life was almost synchronous with the introduction of electric telegraphy into Germany, many of his inventions and discoveries relate to telegraphic apparatus. In 1847 he suggested the use of gutta-percha as a material for insulating metallic conductors. Then he investigated the electrostatic charges of telegraph conductors and their laws, and established methods for testing underground and submarine cables and for locating faults in their insulation (*see* TELEGRAPH: *Submarine Telegraphy*); further, he carried out observations and experiments on electrostatic induction and the retardation it produced in the speed of the current. He also devised apparatus for duplex and diplex telegraphy, and automatic recorders. He suggested that the unit of electrical resistance should be taken as the resistance of a column of pure mercury one metre high and one square millimetre in cross-section, at a temperature of 0° C. Another task to which he devoted much time was the construction of a selenium photometer. He also claimed to have been, in 1866, the discoverer of the principle of self-excitation in dynamo-electric machines. Siemens wrote several papers on meterological subjects, discussing among other things the causation of the winds and the forces which produce, maintain and retard the motions of the air. In 1886 he devoted half a million marks to the foundation of the Physikalisch-Technische Reichsanstalt at Charlottenburg, and in 1888 he was ennobled. He died at Berlin on Dec. 6, 1892. His scientific memoirs and addresses were collected and published in an English translation in 1892, and three years later a second volume appeared, containing his technical papers.

SIEMENS, SIR WILLIAM [KARL WILHELM] (1823–1883), British inventor, engineer and natural philosopher, was born at Lenthe in Hanover on April 4, 1823. After being educated in the polytechnic school of Magdeburg and the University of Göttingen, he visited England at the age of nineteen in the hope of introducing a process in electroplating invented by himself and his brother Werner. The invention was adopted by Messrs. Elkington, and Siemens returned to Germany to enter, as a pupil, the engineering works of Count Stolberg at Magdeburg. In 1844 he was again in England with another invention, the "chronometric" or differential governor for steam engines. Finding that British patent laws afforded the inventor a protection which was then wanting in Germany, he thenceforth made England his home; in 1859 he became a naturalized British subject. After some years spent in active invention and experiment at mechanical works near Birmingham, he went into practice as an engineer in 1851. He worked mainly in two distinct fields, the applications of heat and the applications of electricity. Siemens became F.R.S. in 1862; he was president of many professional societies and the recipient of academic honours. He died in London on Nov. 19, 1883.

In the application of heat Siemens's work began just after J. P. Joule's experiments had placed the doctrine of the conservation of energy on a sure basis. Siemens, in the light of the new ideas, sought to improve the efficiency of the steam engine as a converter of heat into mechanical work. He applied the regenerator to the steam engine and later he attempted to apply it to internal combustion or gas engines. In 1856 he introduced the regenerative furnace, the idea of his brother Friedrich (1826–1904), which avoids the loss of heat by the hot gases which pass up the chimney. But another invention was required before the regenerative furnace could be thoroughly successful. This was the use of gaseous fuel, produced by the crude distillation and incomplete combustion of coal in a distinct furnace or gas-producer. The complete invention was applied at Chance's glass-works in Birmingham in 1861, and furnished the subject of Faraday's farewell lecture to the Royal Institution. It was soon applied to many industrial processes, but it found its greatest development a few years later at the hands of Siemens himself in the manufacture of steel. To produce steel directly from the ore, or by melting together wrought-iron scrap with cast-iron upon the open hearth, had been in his mind from the first, but it was not till 1867, after two years of experiment in "sample steel works" erected by himself for the purpose, that he

achieved success. The product is a mild steel of exceptionally trustworthy quality, the use of which for boiler-plates has done much to make possible the high steam-pressures that are now common, and has consequently contributed, indirectly, to the improvement in the thermodynamic efficiency of heat engines. Just before his death Siemens was at work on a plan to use gaseous fuel from a Siemens producer in place of solid fuel beneath the boiler, and to apply the regenerative principle to boiler furnaces. He believed that gaseous fuel would in time supersede solid coal for domestic and industrial purposes; and among his last inventions was a house grate to burn gas along with coke, which he regarded as a possible cure for city smoke.

In electricity Siemens's name is closely associated with the growth of land and submarine telegraphs, the invention and development of the dynamo, and the application of electricity to lighting and to locomotion. In 1860, with his brother Werner, he invented the earliest form of what is now known as the Siemens armature; and in 1867 he communicated a paper to the Royal Society "On the Conversion of Dynamical into Electrical Force without the aid of Permanent Magnetism," in which he announced the invention by Werner Siemens of the dynamo-electric machine, an invention which was also reached independently and almost simultaneously by Sir Charles Wheatstone and by S. A. Varley. The Siemens-Alteneck or multiple-coil armature followed in 1873. While engaged in constructing a trans-Atlantic cable for the Direct United States Telegraph Company, Siemens designed the very original and successful ship "Faraday," by which that and other cables were laid. One of the last of his works was the Portrush and Bushmills electric tramway, in the north of Ireland, opened in 1883, where the water-power of the river Bush drives a Siemens dynamo, from which the electric energy is conducted to another dynamo serving as a motor on the car. In the Siemens electric furnace the intensely hot atmosphere of the electric arc between carbon points is employed to melt refractory metals. Another of the uses to which he turned electricity was to employ light from arc lamps as a substitute for sunlight in hastening the growth and fructification of plants. Among his miscellaneous inventions were the differential governor, and a highly scientific modification of it, described to the Royal Society in 1866; a water-meter which acts on the principle of counting the number of turns made by a small reaction turbine through which the supply of water flows; an electric thermometer and pyrometer, in which temperature is determined by its effect on the electrical conductivity of metals; an attraction meter for determining very slight variations in the intensity of a gravity; and the bathometer, by which he applied this idea to the problem of finding the depth of the sea without a sounding line.

Siemens's writings consist for the most part of lectures and papers scattered through the scientific journals and the publications of the Royal Society, the Institution of Civil Engineers, the Institution of Mechanical Engineers, the Iron and Steel Institute, the British Association, etc.

See William Pole's *Life* of Siemens (1888). (J. A. E.)

SIEMENS. The founder of the Siemens Concern was Werner Siemens, who as a young artillery officer in 1847 started a repair shop for telegraphy apparatus in a few humble rooms in the back-yard of a Berlin apartment house. Scarcely one year after beginning Siemens received an order from the German Government to instal a complete telegraph line running from Berlin to Frankfurt a/M. In spite of the increase of his undertaking, Werner Siemens found time to pursue scientific studies and he succeeded in making one of the most practical inventions, the modern dynamo-machine, which converts mechanical into electric energy.

The year 1866, when this machine was invented, is the beginning of our modern science of electro-technics. In 1879 at a Berlin trade exhibition Messrs. Siemens and Halske demonstrated the first electrical railway and the name of Siemens very soon became known even beyond the frontiers of Germany as that of an electrical undertaking comprising all branches of electro-technics, telephony, electric power and light.

The branches of telephony and electro-chemistry were separated from the rest in 1903 and were conducted as separate departments under the style of Siemens and Halske, whereas the departments dealing with heavy current problems and the Nürnberg firm of Schuckert and Co. formed the foundation of the Siemens Schuckertwerke.

The Siemens Bauunion was created to deal with the civil engineering branch of the works, connected with underground railways, power plants, hydro-electric works, etc.

The Siemens Concern employs to-day more than 110,000 workmen, including engineers and commercial staff, who work partly in the various factories forming a district of Greater Berlin called Siemensstadt and partly in the factories, which belonged previously to the Schuckert Co. in Nürnberg, and which have since been largely extended.

Recently the turbine works at Mühlheim on the Ruhr were acquired; there steam turbines are manufactured. There are further, under the control of the Siemens Concern, a number of other works, engaged in the supply of accessories and sundry parts for the principal factories. (L. F. Sz.)

SIEMENS' STEEL: *see* Iron and Steel.

SIENA, a city and archiepiscopal see of Tuscany, Italy, capital of the province of Siena, 59 m. by rail S. of Florence and 31 m. direct. Pop. (1921), 32,768 (town); 43,879 (commune). The area of the city within the walls is about 2½ sq.m., and the height above sea-level, 1,115 feet. The plan, spreading from the centre over three hills, closely resembles that of Perugia. The city possesses a university, founded in 1203 and limited to the faculties of law and medicine (447 students in 1925–26).

The horse races of Siena known as the "Palio delle Contrade" have a European celebrity. They are held in the public square, the curious and historic Piazza del Campo (now Piazza di Vittorio Emanuele) in shape resembling an ancient theatre, on the 2nd of July and the 16th of August of each year; they date in their present form from the 17th century and were instituted in commemoration of victories and in honour of the Virgin Mary (the old title of Siena having been "Sena vetus civitas Virginis"). Siena is divided into 17 *contrade* (wards), each with a distinct appellation and chapel and flag of its own; and every year 10 of these *contrade*, chosen by lot, send each one horse to compete for the prize *palio* or banner. The aspect of Siena during these meetings is very characteristic, and the whole festivity bears a mediaeval stamp in harmony with the architecture and history of the town.

Among the noblest fruits of Sienese art are the public buildings adorning the city. The cathedral, one of the finest examples of Italian Gothic architecture, obviously influenced in plan by the abbey of S. Galgano (*infra*), built in black and white marble, was begun at the end of the 12th century, but interrupted by the plague of 1248 and wars at home and abroad, and by 1325 a great part of it and the baptistery of San Giovanni were completed; a further enlargement (which would have made what had been already built into merely a transept of a larger church) was begun in 1339 but never carried out and a few ruined walls and arches alone remain to show the magnificence of the uncompleted design, which would have produced one of the largest churches in the world. In 1355 the construction of the older church was resumed.

The splendid west front, of tricuspidal form, enriched with a multitude of columns, statues and inlaid marbles, dates from 1377 *seq.*: it closely resembles that of Orvieto, which is earlier in date (begun in 1310). Both façades have been recently restored, and the effect of them not altogether improved by modern mosaics. The fine Romanesque campanile belongs to the first half of the 14th century. Conspicuous among the art treasures of the interior is the well-known octagonal pulpit by Nicolò Pisano, dating from 1265–68. It rests on columns supported by lions and is finely sculptured. Numerous statues and bas-reliefs by Renaissance artists adorn the various altars and chapels. The cathedral pavement is inlaid with designs in colour and black and white, representing biblical and legendary subjects; the finest portions beneath the domes, with scenes from the history of Abraham, Moses and Elijah, are by Domenico Beccafumi and are executed with marvellous boldness and effect. The choir stalls also deserve mention: the older ones (from S. Benedetto, a church long ago destroyed)

are in *tarsia* work; the others, dating from the 16th century, are carved from Riccio's designs. The Piccolomini library, adjoining the *duomo,* was founded by Cardinal Francesco Piccolomini (afterwards Pius III.) in honour of his uncle, Pius II. Here are Pinturicchio's famous frescoes of scenes from the life of the latter pontiff, and the collection of choir books (supported on sculptured desks) with splendid illuminations by Sienese and other artists. The church of San Giovanni, the ancient baptistery, beneath the cathedral is approached by an outer flight of marble steps built in 1451. It has a beautiful but incomplete façade designed by Giovanni di Mino del Pellicciaio in 1382, and a marvellous font with bas-reliefs by Donatello, Ghiberti, Jacopo della Quercia and other 15th-century sculptors. The Opera del Duomo contains Duccio's famous Madonna (or Maestà) painted for the cathedral in 1308–11, and other works of art.

Among the other churches are S. Maria di Provenzano, a vast building of some elegance, designed by Schifardini (1594); Sant' Agostino, rebuilt by Vanvitelli in 1755, containing a Crucifixion and Saintes by Perugino, a Massacre of the Innocents by Matteo di Giovanni and the Coming of the Magi by Sodoma; the beautiful church of the Servites (15th century), which contains another Massacre of the Innocents by Matteo di Giovanni and other good examples of the Sienese school; San Francesco, recently restored, containing fine paintings by the two Lorenzetti and others, close to which is the 15th century oratory of S. Bernardino, with fine frescoes by Sodoma, Pacchia and Beccafumi (1518–32) and a good ceiling (1496); San Domenico, a fine 13th-century brick building with a single nave and transept, containing Sodoma's splendid fresco, the Swoon of St. Catherine, and a contemporary portrait of the saint in a fresco by Andrea di Vanni. This church crowns the Fontebranda hill above the famous fountain of that name immortalized by Dante, and in a steep lane below stands the house of St. Catherine, now converted into a church and oratory, and maintained at the expense of the inhabitants of the Contrada dell' Oca. It contains some good works of art, but is chiefly visited for its historic interest. The Accademia di Belle Arti contains a good collection of pictures of the Sienese school, illustrating its development.

The Palazzo Pubblico in the Piazza del Campo (1288–1309) built of brick, is a fine specimen of pointed Gothic, and was designed by Agostino and Agnolo. The light and elegant tower (Torre del Mangia) soaring from one side of the palace (1338–48) is 334 ft. high, and the chapel standing at its foot as a public thank-offering after the plague of 1348 was begun in 1352 and completed in 1376. The interior is lined with works of art. The two ground-floor halls contain a Coronation of the Virgin by Sano di Pietro and a splendid Resurrection by Sodoma. In the Sala dei Nove or della Pace above are the noble allegorical frescoes of Ambrogio Lorenzetti, representing the effects of just and unjust government; the Sala del Mappamondo is painted by Simone Martini and others, the Cappella della Signoria by Taddeo di Bartolo, and the Sala di Consistoro by Beccafumi. Another hall, the Sala di Balia, has frescoes by Spinello Aretino (1408) with scenes from the life of Pope Alexander III., while yet another has been painted by local artists with episodes in recent Italian history. The former hall of the grand council, built in 1327, was converted into the chief theatre of Siena by Riccio in 1560, and, after being twice burnt, was rebuilt in 1753 from Bibbiena's designs. Another Sienese theatre, that of the Rozzi, in Piazza San Pellegrino, designed by A. Doveri and erected in 1816, although modern, has an historic interest as the work of an academy dating from the 16th century, called the Congrega de' Rozzi, that played an important part in the history of the Italian comic stage.

The city is adorned by many other noble edifices both public and private, among which the following palaces may be mentioned: Tolomei (1205); Buonsignori, an elegant mediaeval brick construction; the Palazzo del Capitano di Giustizia; Sansedoni; Marsili; Piccolomini, now belonging to the Government and containing State archives; Saracini; Piccolomini delle Papesse, like the other Piccolomini mansion, designed by Bernardo Rossellino, and now the Banca d'Italia; the enormous block of the Monte de' Paschi, a bank of considerable wealth and antiquity, enlarged and partly rebuilt in the original style between 1877 and 1881; the old Dogana and Salimbeni palaces; the Palazzo Spannochi, a fine early Renaissance building by Giuliano da Maiano; the Loggia di Mercanzia (1417–28) imitating the Loggia dei Lanzi at Florence, with sculptures of the 15th century; the Loggia del Papa, erected by Pius II.; and other fine buildings. We may also mention the two celebrated fountains, Fonte Gaia and Fontebranda; the former in the Piazza del Campo, by Jacopo della Quercia (1409–19), but freely restored in 1868, the much-damaged original reliefs being now in the Opera del Duomo; the Fonte Nuova, near Porta Ovile, by Camaino di Crescentino, also deserves notice (1298). Thanks to all these architectural treasures, the narrow Sienese streets with their many windings and steep ascents are full of picturesque charm, and, together with the collections of excellent paintings, foster the local pride of the inhabitants and preserve their taste and feeling for art. The mediaeval walls and gates are still in the main preserved. The ruined Cistercian abbey of S. Galgano, founded in 1201, with its fine church (1240–68) is interesting and imposing. It lies some 20 m. south-west of Siena.

A kind of marzipan, known as *panforte,* is a speciality of Siena, and ironwork and wood carving are still carried on.

Literary History.—The literary history of Siena begins (13th century) with Folcacchiero the humorist, Cecco Angiolieri, and Bindo Bonichi. Next comes St. Catherine (Benincasa) of Siena (1347–80: *q.v.*) and St. Bernardino (Albizzeschi) of Siena (1380–1444), a popular preacher. Pope Pius II. (*q.v.*) may also be mentioned, as well as several members of the Sozzini family, one of whom, Lelio (1525–62), founded the sect of the Socinians; Bernardino Ochino (1487–1564), a supporter of Protestantism, the satirist Girolamo Gigli (1660–1722) and the economist Sallustio Bandini (1677–1760).

Art.—Lanzi happily designates Sienese painting as "Lieta scuola fra lieto popolo" ("the blithe school of blithe people"). The special characteristics of its masters are freshness of colour, vivacity of expression and distinct originality. The Sienese school of painting owes its origin to the influence of Byzantine art; but it improved that art, impressed it with a special stamp and was for long independent of all other influences. Consequently Sienese art seemed almost stationary among the general progress and development of the other Italian schools, and preserved its mediaeval character down to the end of the 15th century, when the influence of the Umbrian and—to a slighter degree—of the Florentine schools began to penetrate into Siena, followed a little later by that of the Lombard. The first master of real significance was Duccio di Buoninsegna (*c.* 1260–1318); then followed Simone Martini (or Memmi), Lippo Memmi, Pietro and Ambrogio Lorenzetti, and Taddeo di Bartolo, to name only the principal painters. In the 15th century we have Domenico di Bartolo, Sano di Pietro, Giovanni di Paolo, Stefano di Giovanni (Il Sassetta) and Matteo di Giovanni di Bartolo, who fell, however, behind their contemporaries elsewhere, and made indeed but little progress. The 16th century boasts the names of Bernardino Fungai, Guidoccio Cossarelli, Giacomo Pacchiarotto, Girolamo del Pacchia and especially Baldassare Peruzzi (1481–1537), who while especially celebrated for his frescoes and studies in perspective and chiaroscuro was also an architect of considerable attainments (*see* ROME); Giovanni Antonio Bazzi, otherwise known as Il Sodoma (1477–1549), who, born at Vercelli in Piedmont, and trained at Milan in the school of Leonardo da Vinci, came to Siena in 1504 and there produced some of his finest works, while his influence on the art of the place was considerable; Domenico Beccafumi, otherwise known as Micharino (1486–1551), noted for the Michelangelesque daring of his designs; and Francesco Vanni.

There may also be mentioned many sculptors and architects, such as Lorenzo Maitani, architect of Orvieto cathedral (1275–1330), Camaino di Crescentino and his son Tino di Camaino, sculptor of the monument to Henry VII. in the Campo Santo of Pisa; Lando di Pietro, entrusted by the Sienese commune with the proposed enlargement of the cathedral (1339), and perhaps author of the famous Gothic reliquary containing the head of S. Galgano in the Chiesa del Santuccio, which, however, is more usually attributed to Ugolino di Vieri, author of the tabernacle in the cathe-

dral at Orvieto, or Jacopo della Quercia (1371–1438), the creator of the Fonte Gaia, in the Piazza del Campo; Lorenzo di Pietro (Il Vecchietta), a pupil of Della Quercia; Antonio Federighi (d. 1490); Neroccio di Bartolommeo (1447–1500); Francesco d'Antonio, a skilful goldsmith of the 16th century; Francesco di Giorgio Martini (1439–1502), painter, sculptor, military engineer and writer on art; Giacomo Cozzarelli (1453–1515); and Lorenzo Mariano, surnamed Il Marrina (1476–1534). Wood carving also flourished here in the 15th and 16th centuries, and so also did the ceramic art. According to the well-known law, however, the Renaissance, made for the people of the plains, never fully took root in Siena, as in other parts of Tuscany, and the loss of its independence and power in 1555 led to a suspension of building activity, so that the baroque of the 17th and the classicism of the 18th centuries have had hardly any effect here; and few towns of Italy are so unspoilt by restoration or the addition of incongruous modern buildings, or preserve so many characteristics and so much of the real spirit (manifested to-day in the grave and pleasing courtesy of the inhabitants) of the middle ages, which its narrow and picturesque streets seem to retain. Siena is, indeed, unsurpassed for its examples of 13th and 14th century Italian Gothic, whether in stone or in brick.

HISTORY

Siena was an ancient city of the Etruscans; in the time of Augustus it was a Roman colony, known as *Saena Julia.* There are, however, very few relics of antiquity found there. The present city is almost entirely mediaeval. It has been the seat of a bishopric since the 7th century and possibly earlier; and the development of Sienese history is closely connected with the growth of the Church and the power of the episcopate. Under the rule of the Lombards in the 8th century Siena was governed by *Gastaldi* and was not subject to the dukes of Tuscany; in the quarrel between the bishops of Siena and of Arezzo, the *Gastaldi* were supported by the people in their adherence to the cause of their bishops; and the counts who, in the time of Charlemagne, superseded the *Gastaldi,* were also faithful to the church in civic matters, until in the 11th century, after 1056, the bishops gradually made themselves independent, at any rate within the city, of the counts and the consuls who succeeded them. During the 12th century the consuls, who were patricians, had to make concessions to the plebeians; and in 1137 there was a government by 100 nobles and 50 plebeians. Just as the power of the counts yielded to the bishops', and the bishops' to the consuls', so the nobles had to give way, until in 1199 there was a government by a foreign *podestà;* so Siena became a feudatory of the Italian kingdom, and was a tenant *in capite* of the emperor. Her rule was admitted by the lords of the neighbouring country, who were in the same relation to her as was Siena to the emperor, who welcomed on his side, as against Florence, the growing power of the city and *contado.*

Florentine Wars.—Yet the great quarrel between Siena and Florence in the 13th century would have probably occurred if there had been neither pope nor emperor, neither Guelf nor Ghibelline. The conflict was primarily economic. Siena at the beginning of the 13th century was the bank and trade-capital of Italy; for the freedom of trade the Sienese bankers and traders desired to keep safe the master roads to Rome, to the sea, and to the North. It was for this purpose that she made feudatories of the neighbouring lords, in an effort to associate them with her enterprise. Florence, desiring also a commercial supremacy, was Siena's natural enemy. She supported those lords who were irked by their allegiance to the city, and resisted the efforts of the Sienese to establish themselves in such key positions as Montepulciano in the south, or Poggibonsi in the north. So the history of Siena in this century is a history of futile and ultimately hopeless wars—wars to secure the fidelity of her feudatories, a struggle which must involve her in conflict with Florence. In 1254 a treaty was concluded between the two cities; but three years later Florence found a pretext of war in the fact that Siena had given shelter to Ghibellines she had expelled. Siena appealed to Manfred for military assistance while Florence equipped a large citizen army. The first victory, though small, was Florence's, whose forces on May 18, 1260 conquered a small force outside Siena; but on Sept. 4 the Florentines were signally defeated, and the Guelf cause for the moment lost.

Had Manfred lived the course of history might have been different: but his death, and a defeat at Benevento (1266) badly damaged the Ghibellines. The cause of the Guelfs made more and more adherents throughout Italy. Lucca, Pistoia, Volterra joined the party and the succession of Charles of Anjou to the throne of Naples added greatly to its prestige. Siena was disheartened, too, by the death of Provenzano Salvani, who was killed in cold blood by his captor in the battle of Calle do Valdelsa (1269), and Siena's loyalty to the Ghibellines was also shaken by the growth in the city of a strong Guelf and popular party. There was war in the *contado* and unrest in the city, and in 1273 when Charles of Anjou visited Siena, there was nothing but sentiment left for the Ghibelline side; Siena had lost any chance of wresting the supremacy from Florence by espousing the cause of the Guelfs. For while Siena might have gained a position of power as leader of the Ghibellines she was hopelessly outclassed by other cities when she joined the increasing party of the Guelfs.

To her wars with Florence were added internal dissensions. The rule of the nobles had become so tyrannical that in 1277 it was decreed that no patrician could occupy the chief magistracy; power was to remain in the hands of the middle-classes and traders who were adherents of the Guelfs. The size of the magistracy—which had varied from 24 to 36 members—was reduced to 15 in 1280, and seven years later to nine. This government by nine merchants was successful for about 70 years, and under it Siena, while she may have lost in political importance, gained much in peace and prosperity. Florence was no longer alarmed at a possible rival, trade flourished, the university was reorganized with the help of scholars from Bologna, great buildings were constructed—indeed for this period Siena is as good an example as one could wish of a successful oligarchic plutocracy.

The 14th Century.—In the early years of the 14th century there were many minor riots and battles, and in 1355 when the Emperor Charles IV. passed through Siena he gave his blessing to an irregular government of 12 which had been set up by the reformers against the nine. Power was given to the proletarians —the lower classes called *ordini* and *monti;* but they depended for not a little of their authority on the backing of the nobles. It was really a rising of the patricians and the plebeians against the tradesmen. The whole city was faction-ridden, and there is nothing but a dreary passing back of power from one set to another. Charles IV. intervened in 1368 on behalf of a rebellion; and he with Malatesta di Rimini attacked the public palace and was completely defeated by the Sienese who rallied to the call of the 15. The emperor was captured, and used his imprisonment to borrow money from Biccherna, for which he granted Siena a *privilegium* and appointed the magistrates imperial vicars for ever in Siena and the district. After this the new government had the usual difficulties with the dissatisfied and the unenfranchised, and took refuge in the usual device of creating a special police, whose chief was called *esecutore,* which should repress the activities of the nobles. The continuance of internal disorders was naturally an incentive to those forces outside the city proper. The lords, who had once been feudatories to the growing power of the Ghibelline city, threw off its yoke and were helped in their disloyalty by mercenary companies from Brittany and Gascony.

The age-long quarrel between Siena and Arezzo gained a new impetus from the contentions between Carlo di Durazzo and Louis of Anjou for the crown of Naples. First Durazzo held Arezzo,

and then Louis; but when the Sienese hoped to win the city thus ravaged by two alien lords, Louis sold Arezzo to Florence (1384), whose might was too formidable and whose claim on Arezzo was too close for Siena to dispute. Disappointed of this addition to their suzerainty, the Sienese turned on the reformers who had managed and mismanaged their affairs. A successful revolution was concluded in 1385, and resulted in the expulsion of many families on whose industry and experience in trade the prosperity of Siena largely depended. Once more there was a change in the form of government. In 1387 there was a renewal of war between Florence and Siena, who called to aid her Gian Galeazzo, duke of Milan, who made himself master of Siena, and the city became the property of one tyrant until 1403.

The 15th Century.—The city now became involved in the schism which was threatening the very life of the Papacy. Siena, as well as Florence, declared itself against Gregory XII (1409); and Ladislaus of Naples, his supporter attacked Sienese territory. His death ended this war; and then came another conflict with Florence, which supported Venice and Eugenius IV., while Siena favoured Milan and the king of the Romans. In 1433 the warring parties made peace. There was another affray with Florence in 1454; and in a year or two later some of the citizens plotted to hand over Siena to Alphonso of Naples, whose death ended the conspiracy. In these years the magistracy was strengthened by the creation of an extraordinary body, the *balia,* which could act independently of the ordinary council. When Aeneas Sylvius Piccolomini was elected pope in 1455, the Sienese readmitted the nobles to a share in the government, a special concession which came to an end with the pope's death in 1464; although any members of the Piccolomini house were declared, *eo ipso,* to be *popolani* and privileged. In 1480, after the conclusion of the war of Milan and Florence against Naples and the pope, Alphonso, duke of Calabria, tried to obtain suzerainty of Siena. An alliance between the *noveschi* and some of the plebeians favoured his claims, and a revolt (June 1480) ended in a reorganization of the government. The old reformers as such were excluded, and the power vested in the hands of the *popolani* and a body called *aggregati,* consisting of nobles, and citizens of other orders who had not before been allowed to take office. The Neapolitan royal family, however, fell out of favour in 1487, when the king of Naples gave some of the Sienese territories to Florence. For nine months there were riots in the city which culminated on Feb. 20, 1483. The *popolani* took again the spoils of office. But in 1487 the *noveschi,* prosperous, influential tradesmen, returned, and overthrew the *popolani,* and placed the State of Siena under the patronage of Our Lady.

The 16th Century.—Her legate in government was a returned exile, Pandolfo Petrucci, who was till his death in 1512 master of Siena. He was a thoroughly sensible tyrant. Expelled by Cesare Borgia in 1502, he was restored through the intervention of the Florentine Government and the king of France in March 1503. A contemporary chronicler who was no friend of Pandolfo, says that he can be named *cum Joanne Bentivolio et Laurentio Medici.* He founded no dynasty of permanence, and in 1522 Siena became a free city under the protection of the Emperor Charles V.

On Aug. 5, 1552, the Spanish "protection" ended. To attain this end Siena had called in Cosimo of Florence as well as France, and once more she suffered from the possession of powerful friends. There were battles and desperate diplomacies; until in 1555 the Spaniards, having defeated the French, took possession of the town; Philip II. of Spain then gave Siena to Cosimo I. de'Medici, head of her old rival Florence. Her separate history as a city-state ceases, though she retained a separate administration for another 200 years. In 1859 she once more took a leading part in the politics of Italy, for Siena was the first Tuscan city to vote for the annexation of Piedmont and the monarchy of Victor Emmanuel II.

Siena to-day is a city of 32,800 inhabitants, an archiepiscopal see, capital of a province and seat of a university. It is celebrated for the celebration of Il Palio, a race in which each ward competes for a banner; it is held on July 2 and Aug. 10, and its horses race in the old Piazza del Campo.

SIENETJO, a Shangalla tribe living in south-west Abyssinia near the Sudan frontier, perhaps a remnant of the primitive population. They are apparently Hamitic and have a yellowish skin. Their women never intermarry with the Negroes or Arabs. Sienetjo villages are usually built on hilltops. They are an industrious people, skilful jewellers, weavers and smiths.

SIENKIEWICZ (Syĕn-kyĕ'vĭch), **HENRYK** (1846–1916), Polish novelist, was born at Wola Okrzejska near Lukow, in Siedlce, Russian Poland. He studied philosophy at Warsaw university. His first work, a humorous novel entitled *A Prophet in his own Country,* appeared in 1872. In 1876 Sienkiewicz visited America, and contributed an account of his travels to the *Gazeta Polska.* His best-known romance, *Quo Vadis?,* a study of Roman society under Nero, has been translated into more than 30 languages. Originally published in 1895, *Quo Vadis?* was first translated into English in 1896, and dramatized and film versions of it have been produced in many countries. Of greater literary merit is the trilogy of novels describing 17th-century society in Poland during the wars with the Cossacks, Turks and Swedes. This trilogy comprises *Ogniem i mieczem* ("With Fire and Sword," 1890, 1892 and 1895), *Potop* ("The Deluge," Boston, Mass., 1891) and *Pan Woxodyjowski* ("Pan Michael," 1893). Among other very successful novels and collections of tales which have been translated into English are *Bez Dogmatu* ("Without Dogma," 1893; Toronto, 1899), *Janko muzykant: nowele* ("Yanko the Musician and other stories," Boston, Mass., 1893), *Krzyżacy* ("The Knights of the Cross," numerous British and American versions), *Hania,* ("Hania," 1897) and *Ta Trzecia* ("The Third Woman," 1898). Sienkiewicz lived much in Cracow and Warsaw, and for a time edited the Warsaw newspaper *Slowo;* he also travelled in England, France, Italy, Spain, Greece, Africa and the East, and published a description of his journeys in Africa. In 1905 he received the Nobel prize for literature. During the early years of the World War, he devoted his energies to the organization of relief for its Polish victims. He died in Switzerland in 1916 while engaged on that task. His body was transferred to Cracow in 1924.

For a bibliography of the English translations of Sienkiewicz's writings, *see* W. L. Phelps, *Essays on Modern Novelists* (1910). *See* also Monica M. Gardner, *The Patriot Novelist of Poland: Henryk Sienkiewicz* (1926).

SIERADZ, a small town of Poland, in the province of Lodz, situated on the Warta, 110 m. S.W. of the city of Warsaw. It is one of the oldest towns of Poland, founded prior to the introduction of Christianity, and was formerly known as Syra or Syraz. The annals mention it in 1139. Several *seims,* or diets, of Poland were held there during the 13th to 15th centuries, and it was a wealthy town until nearly destroyed by a fire in 1447. The old castle, which suffered much in the Swedish war of 1702–1711, was destroyed by the Germans in 1800. There are two churches, dating from the 12th and 14th centuries respectively.

SIERO, a town of northern Spain, in the province of Oviedo, on the river Nora, and on the Oviedo-Infiesto railway. Pop. (1920) 27,210.

SIERRA LEONE, a British colony and protectorate on the west coast of Africa. It is bounded west by the Atlantic, north and east by French Guinea and south by Liberia. Area about 27,250 sq.m.; pop. (1921) 1,541,311, of whom 1,161 were white and 599 Asiatics (mostly Syrian traders). The coast-line, following the indentations, is about 400 m. in length, extending from 9° 2′ N. to 6° 55′ N. It includes the peninsula of Sierra Leone—23 m. long with an average breadth of 14 m.—Sherbro and minor islands, also Turner's peninsula, a narrow strip of land southward of Sherbro island, extending in a south-east direction about 60 m. and in reality an island. Except in the Sierra Leone peninsula, Sherbro island and Turner's peninsula, the colony proper does not extend inland to a greater depth than half a mile. The protectorate, which adjoins the colony to the north and east, extends from 7° N. to 10° N. and from 10° 40′ W. to 13° W.

Physical Features.—Sierra Leone is a well-watered, hilly country. The seaward face of the Sierra Leone peninsula is traversed by thickly wooded ranges with conical peaks which in Pickett Hill attain a height of 2,912 feet. Elsewhere a low coast plain extends inland 30 to 50 m. The plateau, which forms the greater part of the protectorate, has an altitude varying from 890 to 3,000 ft. On the north-east border, by the Niger sources, are mountains exceeding 5,000 ft. The most fertile parts of the protectorate are Sherbro and Mendiland in the south-west. In the north-west the district between the Great Scarcies and the Rokell rivers is flat, and is named Bullom (low land). In the south-east bordering Liberia is a belt of densely forested hilly country extending 50 m. S. to N. and very sparsely inhabited.

The hydrography of the country is comparatively simple. Six large rivers rise in the Futa Jallon highlands in or beyond the northern frontier of the protectorate and in whole or in part traverse the country with a general south-west course; the Great and Little Scarcies in the north, the Rokell and Jong in the centre, and the Breat Bum and Sulima (or Moa) in the south. These rivers are navigable for short distances, but in general rapids or cataracts mark their middle courses. South of the estuary of the Scarcies the deep inlet known as the Sierra Leone river forms a perfectly safe and commodious harbour accessible to the largest vessels. At its entrance on the southern shore lies Freetown. In the south east the Morro river marks the frontier with Liberia.

Climate.—The climate of the coastal regions is hot and moist, and fever was formerly so prevalent as to earn for Sierra Leone the reputation of being "the white man's grave." On the coast the mean annual temperature is: maximum 88° F, minimum 72° F. The shade temperature rarely rises above 95° F. The rainfall, which varies a great deal, is from 150 to 180 or more inches per annum. The average rainfall at Freetown for the 21 years ended 1916 was 164·8 inches. In 1896 no fewer than 203 in. were recorded. In 1894, a "dry" year, only 144 in. of rain fell. In no other part of West Africa is the rainfall so heavy. December, January, February and March are practically rainless; the rains, beginning in April or May, reach their maximum in July, August and September, and rapidly diminish in October and November. During the dry season, when the climate is much like that of the West Indies, there occur tornadoes and long periods of the *harmattan*—a north-east wind, dry and desiccating, and carrying with it from the Sahara clouds of fine dust, which sailors call "smokes." In the interior the rainfall is less and the temperature lower than on the coast. Exact statistics are lacking.

Flora.—The characteristic tree of the coast districts is the oil-palm. Other palm trees found are the date, bamboo, palmyra, coco and dom. The coast-line, the creeks and the lower courses of the river are lined with mangroves. Large areas are covered with brushwood, among which are scattered baobab, shea-butter, bread-fruit, corkwood and silk-cotton trees. The forests contain valuable timber trees such as African oak or teak (*Oldfeldia Africana*), rosewood, ebony, tamarind, camwood, odum—whose wood resists the attacks of termites—and the tolmgah or brimstone tree. The frankincense tree (*Daniellia thurifera*) reaches from 50 to 150 ft., the negro pepper (*Xylopia Aethiopica*) grows to about 60 ft., the fruit being used by the natives as pepper. There are also found the black pepper plant (*Piper Clusii*), a climbing plant abundant in the mountain districts; the grains of paradise or melegueta pepper plant (*Amomum Melegueta*), and other *Amomums* whose fruits are prized. Both *Landolphia florida* and *Landolphia owariensis* are found. Of several fibre-yielding plants the so-called aloes of the orders Amaryllidaceae and Liliaceae are common. The kola (*Cola acuminata*) and the bitter kola (*Garcinia cola*), the last having a fruit about the size of an apple, with a flavour like that of green coffee, are common. Of dye-yielding shrubs and plants camwood and indigo may be mentioned; of those whence gum is obtained the copal, acacia and African tragacanth (*Sterculia tragacantha*). Besides the oil-palm, oil is obtained from many trees and shrubs, such as the benni oil plant. Of fruit trees there are among others the blood-plum (*Haematostaphis Barteri*) with deep crimson fruit in grape-like clusters, and the Sierra Leone peach (*Sarcocephalus esculentus*). The coffee and cotton plants are indigenous; of grasses there are various kinds of millet, including *Paspalum exile*, the so-called hungry rice or Sierra Leone millet. Ferns are abundant in the marshes.

Fauna.—The wild animals include the elephant, leopard, panther, chimpanzee, grey monkey, antelope of various kinds, buffalo, wild hog, bush goat, bush pig, sloth, civet and squirrel. The hippopotamus, manatee, crocodile and beaver are found in the rivers, and both land and fresh-water tortoises are common. Serpents, especially the boa-constrictor, are numerous. Chameleons, lizards and iguanas abound, as do frogs and toads. Wild birds are not very common; among them are the hawk, parrot, owl, woodpecker, kingfisher, green pigeon, African magpie, the honey-sucker and canary. There are also wild duck, geese and other water fowl, hawk's bill, loggerheads and partridges. Mosquitoes, termites, bees, ants, centipedes, millipedes, locusts, grasshoppers, butterflies, dragonflies, sandflies and spiders are found in immense numbers. Turtle are common on the southern coastline, sand and mangrove oysters are plentiful. Fish abound; among the common kinds are the bunga (a sort of herring), skate, grey mullet and tarpon. Sharks infest the estuaries.

Inhabitants and Towns.—Sierra Leone is inhabited by various negro tribes, the chief being the Mendi, Timni, Limba, Bullom, Koranko and Suba. From the Mendi district many curious steatite figures which have been buried have been recovered and are exhibited in the British Museum. They show considerable skill in carving. Of "Hamitic" races the Fula inhabit the region of the Scarcies. Freetown is peopled by descendants of many negro tribes, and a distinct type known as the Sierra Leoni and popularly called creoles has been evolved; their language is English and pidgin English. The Susu are Mohammedans, but most of the negroes are pagans, and each tribe has its secret societies and fetishes. These are employed often for beneficent purposes, such as the regulation of agriculture and the palm-oil industry. There are many Christian converts and Mohammedans.

Besides Freetown (*q.v.*), the capital, the most important towns for European trade are Bonthe, the port of Sherbro, and Port Lokko, at the head of the navigable waters of a stream emptying itself into the Sierra Leone estuary. Waterloo is a large "creole" town in the Sierra Leone peninsula, in a market-garden district. In the interior are various populous centres. One of the best known is Falaba near the north-east frontier of the protectorate. It lies about 1,600 ft. above the sea. Falaba (pop. about 6,000) was founded towards the end of the 18th century by the Sulima (Yalunka) who revolted from the Fula, and its warlike inhabitants, soon attained supremacy over the neighbouring villages and country. Like many of the native towns, it is surrounded by a loopholed wall, with flank defences for gates. Kambia on the Great Scarcies, a place of some importance, can be reached by boat from the sea. On the railway running southeast from Freetown are Songo Town, Rotifunk, Mano, Bo, Baiima and Pendembu; on the northern railway are Makump, Makena and Kamabai.

Communications.—A railway, State owned and the first built in British West Africa, runs south-east from Freetown through the fertile districts of Mendiland to the Liberian frontier. Begun in 1896, the line reached Bo (136 m.) in the oil-palm district in 1903. It was continued to Baiima (220 m.) in 1905 and ends at Pendembu, a total length of 227½ miles. The gauge throughout is 2 ft. 6 in. The line cost about £1,000,000. From Boia on this line another railway, completed in 1916, goes north to Kamabai. It is 104 m. long. In 1927 the railway accounts were separated from the colony's general accounts. In that year railway revenue was £251,000 and expenditure £269,000.

Cable communication with Europe was established in 1886. Freetown is well served by steamers plying regularly to and from Liverpool, Plymouth, Hamburg and other ports.

Administration, Revenue, etc.—The country is administered as a crown colony, the governor being assisted by an executive and a legislative council. Since 1924 the legislative council has contained three members elected in the colony on the basis of manhood suffrage and also direct (nominated) representatives of the protectorate. The law of the colony is the Common Law

of England modified by local ordinances. There is a denominational system of primary and higher education. The schools are inspected by Government and receive grants in aid. Furah Bay college is affiliated to Durham university. There is a Wesleyan Theological college; a Government school (established 1906) at Bo for the sons of chiefs; a Government agricultural training college for natives at Njola (established 1919); a Government model school at Freetown and the Thomas Agricultural academy at Mabang (founded in 1909 by a bequest of £60,000 from S. B. Thomas, a Sierra Leonian). Since 1901 the Government has provided separate schools for Mohammedans. Revenue is largely derived from customs. In the protectorate a house tax is imposed. Revenue which had been £168,000 in 1899 (when railway building had begun and the protectorate taken over) was £618,000 in 1913 and in 1924, when normal conditions after the World War had returned, was £868,000. Expenditure was £145,000 in 1899; £622,000 in 1913 and £777,000 in 1924. In 1927 revenue (railways excluded) was £719,000 (£534,000 from customs) and expenditure £754,000, the excess of expenditure being provided from previous surplus balance.

The protectorate is divided for administrative purposes into districts, each under a European commissioner. Native law is administered by native courts, subject to certain modifications. The tribal system of Government is maintained, and the authority of the chiefs has been strengthened by the British.

Economic Conditions.—With a population of 55 to the square mile Sierra Leone has a fairly good labour supply: the great majority of the natives prefer, however, to work for themselves rather than for an employer. The wealth and external trade of the country is mainly dependent on the oil-palm, the kola nut being next in value. The Sierra Leonians (as apart from the natives) are traders, not producers, and agriculture proper is still almost confined to the cultivation of food crops for home consumption—chiefly rice and cassava. At one time rubber exports were of some account; this trade virtually ceased about 1910 partly because the rubber tree and vines were overtapped, chiefly through the superiority of plantation rubber grown in the East. The trade in rubber and in other produce, was also affected by the diversion of produce from the interior of French Guinea, which used to be brought by caravan to Sierra Leone, to Konakri. Without transit trade Sierra Leone is dependent on its own resources. In the 20 years 1907–27 the export of palm nuts rose from 35,000 tons to 65,000 tons, of palm oil from 2,600 to 3,600 tons. They formed from 70 to 80% of the local exports. The oil-palm industry was conducted in the wasteful traditional fashion of the natives. The "wild" oil-palm is found by the million, but, despite this unlimited supply, anxiety was caused by the prospective competition of the cultivated oil-palm in the East, and also by the increasing production of copra, which yields an oil similar to that of the palm. The administration therefore, in 1926–27, laid out a model plantation of 2,000 ac. to demonstrate to the natives the advantages of scientific methods of culture. Besides palm nuts and palm oil and the kola nut trade the export of ginger was of next importance. The cultivation of cocoa, however, began to have promising results from 1925. The greatest need for the development of trade was better means of transport. The 330 m. of railway had not been added to since 1916, and in 1926 there were but 400 m. of motor roads; a vigorous road-making campaign began in 1925. Until 1926 it was supposed that the country was without mineral wealth. In that year platinum and haematite were discovered. Subsequently gold, chromite corundum and other minerals were found and by 1929 production had begun.

Cotton goods are the chief imports, next in value are food stuffs and tobacco. Formerly trade spirits (from the continent of Europe) were imported in large quantities, the duty upon them yielding a large share of the revenue, but in accord with international agreements steps were taken to suppress the trade and between 1912 and 1924 the value of spirits imported fell from 6·29 to 1·10 of the total imports. The trade of Sierra Leone grew steadily. It was about £650,000 in 1887 and, excluding specie, had reached £2,782,000 in 1913. In 1924 the figures were:—Commercial imports £1,451,000; commercial exports £1,671,000, of which £1,510,000 represented the value of the local produce. For 1927 the figures (including specie) were:—Imports £2,112,000 (£1,296,000 British); exports £1,757,000. Of these exports £603,000 went to Great Britain. Kola nuts to Senegal, the Gambia and Nigeria. Germany takes a large proportion of the palm nuts (37,000 tons in 1927).

HISTORY

Sierra Leone (in the original Portuguese form Sierra Leona) was known to its native inhabitants as Romarong, or the Mountain, and received the current designation from the Portuguese discoverer, Pedro de Sintra (1462), either on account of the "lion-like" thunder on its hill-tops or to a fancied resemblance of the mountains to the form of a lion. Here, as elsewhere along the coast, the Portuguese had "factories"; and though none existed when the British took possession, some of the natives called themselves Portuguese and claimed descent from colonists of that nation. English traders were established on Bance and the Banana islands as long as the slave trade was legal. The existing colony has not, however, grown out of their establishments, but owes its birth to the philanthropists who sought to alleviate the lot of those negroes who were victims of the traffic in human beings. In 1786 Dr. Henry Smeathman, who had lived for four years on the West Coast, proposed a scheme for founding on the Sierra Leone peninsula a colony for negroes discharged from the army and navy at the close of the American War of Independence, as well as for numbers of runaway slaves who had found an asylum in London. In 1787 the settlement was begun with 400 negroes and 60 Europeans, the whites being mostly women of abandoned character. In 1788 "king" Nembana, a Timni chief, sold a strip of territory for the use of the settlers, and thus the British acquired the best harbour on the whole of the west coast of Africa. The first settlement, not unnaturally, proved a complete failure. In 1791 Alexander Falconbridge (formerly a surgeon on board slave ships) collected the survivors and laid out a new settlement (Granville's Town); and the promoters of the enterprise received a charter of incorporation as the Sierra Leone Company. In 1792 John Clarkson, a lieutenant in the British navy brought the colony 1,100 negroes from Nova Scotia. In 1794 the settlement, which had been again transferred to its original site and named Freetown, was plundered by the French. The governor at the time was Zachary Macaulay, father of Thomas Babington, Lord Macaulay. In 1807, when the inhabitants of the colony numbered 1,871, the company, which had encountered many difficulties, transferred its rights to the Crown. The slave trade having in the same year been declared illegal by the British parliament, slaves captured by British vessels in the neighbouring seas were brought to Freetown, and thus the population of the colony grew. Its development was hampered by the frequent changes in the governorship. Sydney Smith's jest that Sierra Leone had always two governors, one just arrived in the colony and the other just arrived in England, is but a slight exaggeration. In 22 years (1792–1814) there were 17 changes in the governorship. After that date, changes, although not quite so rapid, were still frequent. Many of these changes were due to deaths, but the resources of science have removed the reproach of Sierra Leone being "the white man's grave."

It took a good many years to build up an industrious and self-supporting community out of the heterogeneous human material "dumped down" at Sierra Leone. The settlers, whose language was English and who, for the most part, professed Christianity (the Church Missionary Society began work among them in 1804), were regarded by the natives as aliens and collisions between the settlers and neighbouring tribes were frequent. The settlers, after a time, took to trade and professional careers and as Freetown was a much used port of call for shipping a measure of prosperity was reached.

Hinterland Acquired.—From time to time small additions by purchase were made to the area of the colony, at first partly to cope with the slave trade, which continued to be carried on illicitly. Then, about 1850, a period of discouragement set in

and in 1865 a House of Commons committee reported against any further acquisitions of territory. Nevertheless, if only in the interests of trade, complete indifference to the hinterland was impossible. But the French had penetrated into the interior in a way which threatened to reduce the British possessions to small enclaves. In the task of extending British influence and in endeavours to stop inter-tribal warfare, the British authorities enlisted the services of Dr. Edward W. Blyden (a pure-blooded negro), who in 1872 visited Falaba and in 1873 Timbo, both semi-Mohammedan countries. Falaba—which had been visited in 1869 by Winwood Reade on his journey to the Niger—came definitely under British protection, but Timbo, which is in Futa Jallon, was allowed to become French territory. The area for expansion on the north was in any case limited by the French Guinea settlements, and on the south the territory of Liberia hemmed in the colony. In the east and north-east British officers also found themselves regarded as trespassers by the French.

An accidental collision between British and French troops at Waima (Dec. 23, 1893) showed the necessity for settling the Franco-British frontier. An agreement was signed in 1895, Great Britain securing a compact area something less than the size of Scotland. Over this area a British protectorate was proclaimed (Aug. 26, 1896). Slave raiding and slave dealing were at once declared illegal, and the widespread resentment thus caused was aggravated by the imposition of a hut-tax. A little later, Bai Bureh, a Timni chief, rose in revolt. In April, 1898, there followed a general rising of the Mendi, who began by murdering missionaries (including four women) and a large number of officials and police, chiefly Sierra Leonians, who were as obnoxious to the natives as were the whites. The dreaded "Poro" fetish was used by the chiefs to compel recalcitrants to join them. The insurrection, which cost some thousands of lives, was suppressed with severity.

Slavery Abolished.—Relations between the people of the protectorate and the administration improved gradually. The opening up of the country by railways, the establishment of schools and the support given by Government to the paramount chiefs in the exercise of their legitimate powers, all tended to a better understanding. Progress was slow, however, and was checked by the continued tolerance of domestic slavery. Though from time to time efforts to end it were made, the subject was not very seriously dealt with until 1919, and it was not until 1926 that an ordinance was passed by the local legislature which was intended to remove the last vestige of legal recognition of slavery. Events showed that that ordinance did not effect its purpose, for the supreme court of Sierra Leone decided (July, 1927) that a slave owner had "the right to use reasonable force to re-take a runaway slave." Immediate action was taken to remedy the defect disclosed, and in the following September another ordinance was passed abolishing in express terms the legal status of slavery in the protectorate. This ordinance came into force on Jan. 1, 1928, some 200,000 persons being affected. No great social upheaval followed; the majority of the ex-slaves remained with their former owners and intermarried with their families, while others acquired land and set up on their own account. It was noteworthy that the paramount chiefs with seats on the legislative council—themselves the largest slave-owners—voted in favour of the abolition of slavery and made no demand for compensation. An elective element for the colony and direct representation of the protectorate, was introduced into the legislature for the first time in 1924.

See H. C. Luke, *A Bibliography of Sierra Leone*, 2nd ed. (1925); T. N. Goddard, *The Handbook of Sierra Leone* (1925); *Correspondence Relating to Domestic Slavery in the Sierra Leone Protectorate* (British White Paper Cmd. 3,020, 1928). (F. R. C.)

SIERRA MORENA, THE, is so called because of the long dark line of the southern scarp of the Meseta as seen from the Andalusian plain. It has a mean elevation of about 2,500 feet rising above this in the east toward the steppe region of Albacete. The easternmost and loftiest ridge is called the Sierra de Alcaraz (5,900 ft.), while some of those in the extreme west are classed together as the Sierras de Aracena. The great breadth of the Sierra Morena long rendered it a formidable barrier between Andalusia and the north; as such it has played an important part in the social, economic and military history of Spain. It separates the plateau region of Castile and Estremadura from the Andalusian plain and the highlands of the Sierra Nevada system, and forms the water-shed between two great rivers, the upper Guadiana on the north and the Guadalquivir on the south. Parts of the Sierra Morena are rich in minerals; the central region yields silver, mercury and lead, while the Sierras de Aracena contain the celebrated copper mines of Tharsis and Rio Tinto (*q.v.*).

SIERRA NEVADA, THE, is a range of high mountains south of the basin of Andalusia in southern Spain. It is a well-defined range, stretching from the upper valley of the river Genil or Jenil eastwards to the valley of the river Almería. It owes its name, meaning "the snowy range," to the fact that several of its peaks exceed 10,000 feet in height and are thus above the limit of perpetual snow. Its culminating point, the Cerro de Mulhacen (11,421 ft.) reaches an altitude unequalled in Spain, while one of the neighbouring peaks, called the Picacho de Veleta (11,148 ft.), is only surpassed by Aneto (11,168 ft.), the loftiest summit of the Pyrenees. The Sierra Nevada is composed chiefly of soft micaceous schists, sinking precipitously down on the north, but sloping more gradually to the south and south-east. On both sides deep transverse valleys (*barrancas*) follow one another in close succession, in many cases with round, basin-shaped heads like the cirques of the Pyrenees (*q.v.*). In many of these cirques lie alpine lakes, and in one of them, the Corral de Veleta, there is even a small glacier, the most southerly in Europe. The transverse valleys open on the south into the longitudinal valleys of the Alpujarras (*q.v.*). On the north, east and west there are various minor ranges, such as the Sierras of Parapanda, Harana, Gor, Baza, Lucena, Cazorla, Estancias, Filabres, etc., which are connected with the main range, and are sometimes collectively termed the Sierra Nevada system.

SIERRA NEVADA MOUNTAINS [Span. for "Snowy Peaks"], a geologically young mountain range in western United States which begins at Tehachapi pass in southern California, extends northward 430 m. as part of the boundary between California and Nevada, and ends in southern Oregon where it merges with the Klamath or Siskiyou mountain group. Their geologic history is a fascinating record of relatively recent earth movement. Where they now rise the waters of Paleozoic and early Mesozoic seas laid down sediments, which were intruded by granitic magmas and compressed by heavy folding into lofty summits in mid-Mesozoic time. During the early Cretaceous these newborn mountains were peneplaned, to be uplifted and planed down repeatedly throughout Cretaceous and Tertiary time. Beginning probably in Cretaceous time profound faulting proceeded with down throw toward the east, and a gigantic block of the earth's surface, probably the largest single such block on the face of the earth, began tilting toward the Pacific, forever shutting out its waters from the great interior basin. By the close of Tertiary time a steaming expanse of volcanic mud had buried the whole of the northern Sierra, a chaotic contrast to the peaceful rolling hills of the Miocene time, clothed by verdant tropical vegetation. As the great block tilted more and more, the streams cut deeper and more sharply into the tuff-covered surface and during the late Tertiary and early Quaternary shaped the steep-walled canyons and rugged summits that characterize the Sierra Nevadas, then clothed by a luxuriant vegetation temperate instead of tropic in type. With the beginning of the Pleistocene ice age the summits became mantled in deep snow and glacial ice. The peaks and higher slopes were denuded of their forests, and reduced, upon the disappearance of the ice, to a desolate expanse of dazzling white granite and glaring schists.

For at least the last thousand years, the Sierra Nevada has stood as it is to-day, a wonderland of high rugged mountains, deep mysterious canyons, and glacier-scoured ridges, covered in their lower reaches with oak groves or chaparral thickets, their middle slopes set with sombre giant pines and sequoias, and their summits marked by storm-scarred dwarf pines. The longer, gentler

slope is toward the west, averaging about 200 ft. to the mile; the eastern slope is very steep, at its highest point above the valley opposite Owens lake dropping 10,000 ft. in a distance of 10 miles. Few passes cross the range, Kearsarge and Truckee being the most celebrated. The highest part of the range lies between 36° 30′ and 37° 30′ N. lat. and here the peaks range from 13,000 ft. to 14,502 ft., the latter being the altitude of Mt. Whitney, the highest peak of the range; and all the passes are about 12,000 ft. high. Eleven peaks in the range are above 14,000 feet. From Mt. Whitney the elevation of the range gradually diminishes northward. The precipitation on the foot-hills and lower slopes is relatively light but with altitude it increases rapidly, most of it falling as heavy snow, particularly on the summits, which thus become storehouses of moisture for irrigation and potable waters to supply power, agricultural and domestic needs of the population of the California valleys and coast.

Three main forest belts cover the flanks of the Sierra; the lower or main pine belt with sugar pine, yellow pine, Douglas spruce and incense cedar the dominant species; the silver fir belt with the white silver fir (*Abies concola*), and the red fir (*A. magnifica*) dominant species; and the upper pine belt of tamarack, mountain pine, juniper, hemlock spruce, white pine, nut pine and needle pine dominant with altitude in the order named; and finally at the summits the tangled dwarf pines showing not more than a foot of height or an inch of girth for a century's growth. The big trees (*Sequoia gigantea*) extend through the upper part of the lowest belt and the lower part of the middle belt. The foothills and alluvial fans at the foot of the southern Sierras are characterized by piñon or nut pine, digger pine, blue oak and interior live oak, and an underbrush distinguished by the pungent manzanita, and the rude chamiso.

The fauna of the Sierra is characterized by the ubiquitous Douglas red squirrel, the mountain goat and mountain sheep; white-tailed, black-tailed and occasionally mule deer; grizzly, black, cinnamon and brown bears, now all rare; by representative birds like the Sierra junco, blue-fronted jay, the famous Clarke nut-cracker and others; and by distinctive mountain trout, like the rainbow and the golden. (W. E. E.)

SIEYÈS (Sē-ā-yās), **EMMANUEL-JOSEPH** (1748–1836), French abbé and statesman, one of the chief theorists of the revolutionary and Napoleonic era, born at Fréjus, S. France, on May 3, 1748. He was educated for the church at the Sorbonne; but while there he eagerly imbibed the teachings of Locke, Condillac, and other political thinkers, in preference to theology. Nevertheless he entered the church, and owing to his learning and subtlety advanced until he became vicar-general and chancellor of the diocese of Chartres. At the crisis of 1788, when Necker asked for opinions as to the constitution of the estates Sieyès wrote his celebrated pamphlet, "What is the Third Estate?" He thus begins his answer—"Everything. What has it been hitherto in the political order? Nothing. What does it desire? To be something." For this *mot* he is said to have been indebted to Chamfort. The pamphlet had a great vogue, and its author was elected as the last (the twentieth) of the deputies of Paris to the States General. He strongly advised the constitution of the Estates in one chamber as the National Assembly, but he opposed the abolition of tithes and the confiscation of church lands. Elected to the special committee on the constitution, he opposed the right of "absolute veto" for the king, which Mirabeau unsuccessfully supported. He had a considerable influence on the framing of the departmental system, but after the spring of 1790 his influence was eclipsed by men of more determined character. Only once was he elected to the post of fortnightly president of the Constituent Assembly. Excluded from the Legislative Assembly by Robespierre's self-denying ordinance, he reappeared in the third National Assembly, known as the Convention (September 1792–September 1795); but he effaced himself partly from disgust, partly from timidity. He abjured his faith at the time of the installation of the goddess of reason; and afterwards he characterized his conduct during the reign of terror in the ironical phrase, *J'ai vécu.* He voted for the death of Louis XVI., but not in the contemptuous terms *La mort sans phrases* sometimes ascribed to him.

In 1795 he went on a diplomatic mission to The Hague. He dissented from the constitution of 1795 (that of the Directory) in some important particulars, but without effect, and thereupon refused to serve as a Director of the Republic. In May 1798 he went as the plenipotentiary of France to the court of Berlin in order to try to induce Prussia to make common cause with France against the Second Coalition. His conduct was skilful, but he failed in his main object. He was elected a Director in place of Rewbell in May 1799. Already he had begun to intrigue for the overthrow of the Directory; he now set himself to sap the base of the constitution of 1795. With that aim he caused the revived Jacobin Club to be closed, and made overtures to General Joubert for a *coup d'état* in the future. The death of Joubert at the battle of Novi, and the return of Bonaparte from Egypt marred his schemes; but ultimately he came to an understanding with the young general. After the *coup d'état* of Brumaire, Sieyès produced the perfect constitution which he had long been planning, only to have it completely remodelled by Bonaparte. Sieyès soon retired from the post of provisional consul, which he accepted after Brumaire; he entered the senate, where he defended the arbitrary and illegal proceedings whereby Bonaparte rid himself of the leading Jacobins. During the empire he rarely emerged from his retirement, but at the time of the Bourbon restorations (1814 and 1815) he left France. After the July revolution (1830) he returned; he died at Paris on June 20, 1836. The thin, wire-drawn features of Sieyès were the index of his mind, which was keen-sighted but narrow, dry and essentially limited. His lack of character and wide sympathies was a misfortune for the National Assemblies which he might otherwise have guided with effect.

SIFAKA, the name of three species of large Malagasy lemurs of the genus *Propithecus,* allied to the INDRI (*q.v.*), but distinguished by their long tails. Sifakas are variable in colouring, but always show a large amount of white. (*See* PRIMATES.)

SIGEBERT (d. 575), king of the Franks, was one of the four sons of Clotaire I. At the death of Clotaire in 561 the Frankish kingdom was divided among his sons, Sigebert's share comprising the Rhine and Meuse lands and the suzerainty over the Germanic tribes beyond the Rhine as far as the Elbe, together with Auvergne and part of Provence. At the death of his brother Charibert in 567 Sigebert obtained the cities of Tours and Poitiers, and it was he who elevated to the see of Gregory of Tours (*q.v.*), the historian of the Franks. Sigebert married a royal princess, Brunhilda, daughter of Athanagild, the king of the Visigoths; the nuptials were celebrated with great pomp at Metz, the Italian poet Fortunatus composing the epithalamium. Shortly afterwards Sigebert's brother Chilperic I. married Brunhilda's sister, Galswintha; but the subsequent murder of this princess embroiled Austrasia and Neustria, and civil war broke out in 573. Sigebert appealed to the Germans of the right bank of the Rhine, who attacked the environs of Paris and Chartres and committed frightful ravages. He was entirely victorious, and pursued Chilperic as far as Tournai. But just when the great nobles of Neustria were raising Sigebert on the shield in the villa at Vitry, near Arras, he was assassinated by two bravoes in the pay of Fredegond, Chilperic's new wife. At the beginning of his reign Sigebert had made war on the Avars, who had attacked his Germanic possessions, and he was for some time a prisoner in their hands.

SIGEBERT OF GEMBLOUX (*c.* 1030–1112), mediaeval chronicler, became in early life a monk in the Benedictine abbey of Gembloux. Later he was a teacher at Metz, and about 1070 he returned to Gembloux, where, occupied in teaching and writing, he lived until his death on Oct. 5, 1112. As an enemy of the papal pretensions he took part in the momentous contest between Pope Gregory VII. and the emperor Henry IV.; and he also wrote

against Pope Paschal II. Sigebert's most important work is a *Chronographia*, or universal chronicle, covering the years 381–1111, which is published in vol. vi. of the *Monumenta Germaniae historicae Scriptores*, with valuable introduction by L. C. Bethmann.

SIGEL, FRANZ (1824–1902), German and American soldier, was born at Sinsheim, in Baden, on Nov. 18, 1824. He graduated at the military school at Carlsruhe, and became an officer in the grand ducal service. When the Baden insurrection broke out, Sigel was a leader on the revolutionary side in the brief campaign of 1848 and again in 1849, and then took refuge in Switzerland. A political exile, he emigrated in 1852 to the United States, working in turn as journalist and schoolmaster, and both at New York and St. Louis, whither he removed in 1858, he conducted military journals. When the Civil War broke out in 1861, Sigel was active in raising and training Federal volunteer corps. He became a brigadier-general (U.S. Volunteers), and was with Nathaniel Lyon at Wilson's creek and with J. C. Frémont in the advance on Springfield in the autumn. In 1862 he took a conspicuous part in the desperately fought battle of Pea ridge, which definitely secured Missouri for the Federals. Promoted to be major-general of volunteers he was ordered to Virginia, and was soon placed in command of a corps of Pope's "Army of Virginia." In this capacity he took part in the unsuccessful second Bull Run campaign. In 1864 he was placed in command of the corps in the Shenandoah valley, but was defeated by Gen. John C. Breckinridge at Newmarket (May 15), and was superseded. He resigned his commission in May 1865, and became editor of a German journal in Baltimore, Maryland. In 1867 he removed to New York city where he later served as collector of internal revenue and as pension agent. His last years were devoted to the editorship of the *New York Monthly*, a German-American periodical. He died in New York city on Aug. 21, 1902. A monument (by Karl Bitter) in his honour was unveiled in Riverside drive, New York city, in 1907.

SIGER DE BRABANT (*c.* 1235–1281/84), French philosopher and leader of Latin Averroism at Paris, first came into notice in 1266 during the conflict between the four "nations," when the papal legate decided that Siger was the ringleader. In 1271 he was involved in a similar struggle, the minority among the "nations" choosing him as rector in opposition to the elected candidate, Aubri de Rheims. After three years the matter was settled by the papal legate, Simon de Brion, afterwards Pope Martin IV. and Siger retired from Paris to Liège. Following on the general condemnation of 1277, Siger and Bernier de Nivelles were summoned to appear on a charge of heresy, especially in connection with the *Impossibilia*, but they fled to Italy, Siger being killed at Orvieto by an insane secretary. Dante, in the *Paradiso* (x. 134–6), curiously assigns the praise of Siger to St. Thomas.

The importance of Siger in philosophy lies in his acceptance of Averroism in its entirety, which drew upon him the opposition of his most distinguished contemporaries, including Albertus Magnus and Aquinas, and the condemnations by Bishop Tempier of Paris in 1270 and in 1277. The doctrines which were especially criticized were—the denial of the Divine power to create more than one being; the assertion of the eternity of the world, of the infinity of eternal intelligence, of the unity of intellect in all men, and of the possibility of a double truth—one for revelation and one for reason; the rejection of personal immortality and of the real distinction between essence and existence.

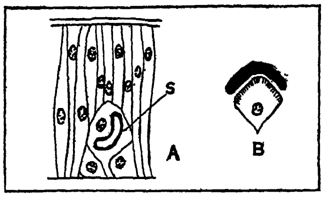
In addition to the opuscula printed in P. Mandonnet's *Siger de Brabant et l'Averroisme latin du XIII^e siècle* (Fribourg, 1899; 2nd ed., 1911), Grabmann has discovered ms. commentaries on some of Aristotle's works, and also ms. *Quaestiones*, described in *Sitz. Berichte Bayer Akad. Wissensch. Philos.-philo. u. hist. Kl.* (1924), and in *Misc. Fr. Ehrle* (1924). *See* also M. de Wulf, *Hist. of Phil.* (2 vols., Eng. trans. 1926), and Überweg. *Gesch. der Phil.* Bd. 2 (1928).

SIGERSON, DORA (*c.* 1870–1918), Irish poet, the daughter of Dr. George Sigerson, was born in Dublin about 1870. In 1896 she married Clement K. Shorter (*q.v.*). She contributed, as a girl, to the *Irish Monthly*, and published several volumes of verse, notably *The Fairy Changeling* (1897), *Ballads and Poems* (1898); and *As the Sparks Fly Upwards* (1904). For her material she drew largely on Irish folk-lore.

SIGHT, SENSE OF. Under the term "eyes" we include organs, or, in the simplest cases, groups of sensory cells, which are specially adapted for the perception of light. Nevertheless, sensitiveness to light can frequently be established for animals in which eyes are not demonstrable. We must assume, therefore, either that the whole surface of the skin is sensitive to light, or that single sensory cells are scattered in the skin which are very inconspicuous in their structure, and which are the bearers of this sense of light perception.

THE STRUCTURE OF THE EYES IN THE LOWER ANIMALS

Already in the Protozoa, however, true eyes are found. In Volvox and other Flagellates they consist of a lens, and, behind this, an accumulation of the plasma, which frequently is pigmented. The earthworm has isolated photo-sensitive cells, which may be distinguished by their structure; the simplest of the vertebrates (*Branchiostoma*) has numerous isolated photo-sensitive cells scattered over the whole of the dorsal nerve cord, each of which is half surrounded by a pigment cell (fig. 1).



AFTER HESSE

FIG. 1.—(A) SECTION THROUGH THE SKIN OF AN EARTHWORM. (S) PHOTO-SENSITIVE CELL, (B) PHOTO-SENSITIVE CELL WITH PIGMENT-CAP FROM BRANCHIOSTOMA

Eyes of the most simple kind originate through the concentration of a number of such photo-sensitive cells in a small space.

Eye-spots.—Eye-spots are found in Medusae, starfishes and some Annelid worms (fig. 2). The first step in the perfecting of this very primitive apparatus is the sinking of the eye-spot into a pit-like depression, thus forming an eye-cup (optic cup). This type already, perhaps, is adapted for the perception of the direction of light, and is of very general occurrence, being found in some worms, gastropods, bivalves, starfishes, Arthropods, etc. (fig. 3). This type of eye when it occurs in Arthropods is called an *ocellus*, and is more complicated, as the thin cuticle, which envelopes the whole of the body, becomes thickened over it, and forms a strongly arched, or occasionally, ball-shaped lens. At the same time division of labour takes place among the cells forming the eye-cup. The sides of this remain transparent, and secrete a kind of vitreous humour, only the cells situated at the back of the cup forming the retina (fig. 4a). In yet other cases two layers may be formed in the optic cup by a peculiar process of folding, which cannot be described here. A vitreous outer layer and an inner retinal layer can then be distinguished (fig. 4b). The open cup-shaped eye may become quite closed in, forming an optic vesicle, by the growing together of the outer margins (as in many Chaetopod worms, gasteropods and cuttlefishes). The interior of this optic vesicle is then filled by a jelly-like substance, the vitreous humour. The anterior portion of the vesicle is transparent, like the skin which grows over it; the inner half becomes the retina (fig. 5). This type of eye is found in its most perfect form in some worms (*Alciope*) and gasteropods (*Helix, Limax*) with the formation of a lens, which is free in the vitreous humour, and condenses the rays of light. The cuttlefish alone shows a further development. This is the highest of all invertebrate animals. In general, as well as in psychical, development, it ranks at least as high as fishes.

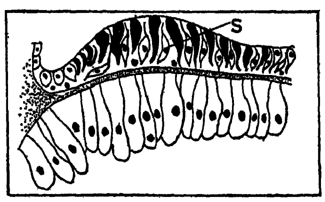


FIG. 2.—EYE-SPOT OF A MEDUSA: S RETINAL CELLS

The eye represented in fig. 6, presents a striking resemblance to that of a vertebrate. All the separate parts of the one are repeated in the other. The posterior chamber is the principal part; it is bounded at the back by the retina, and in front by the

iris. It is filled by a jelly—the vitreous humour.

The lens is spherical, as in fishes. It differs from the lens of a fish, however, in that it does not consist of cells; it is divided by a delicate skin which separates the anterior chamber of the eye from the posterior, half lying to the front, and half to the back.

The anterior chamber is closed by a transparent cornea, in front of which are movable eyelids. The power of accommoda-

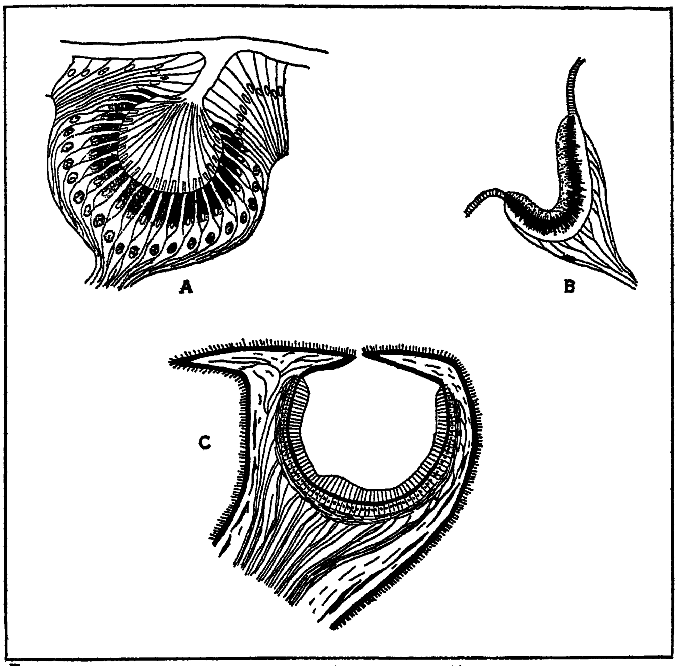

FIG. 3.—OPEN, CUP-SHAPED EYES OF (A) CHAETOPOD WORM (SYLLIS); (B) GASTROPOD, COMMON LIMPET (PATELIA); (C) CHAMBERED CEPHALOPOD (NAUTILUS)

tion is exactly the same as in the vertebrate eye. The cuttlefish can focus its sight either for near vision or for distant by means of particular muscles, which alter the length of the axis of the eye. It is hardly necessary to mention that the pupil in the iris can be expanded or contracted according to the strength of the light falling on it. In the structure of the retina, also, the eye of the cuttlefish is equivalent to those of vertebrates.

It is made up of more than 100,000 elements per sq.mm., and thus is certainly adapted for the formation of a sharp image. Lastly, it may be mentioned, that in size also it is in no way

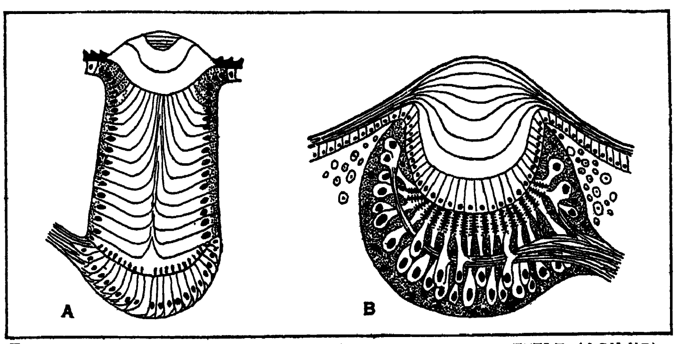

FIG. 4.—CUP-SHAPED EYES OF (A) THE LARVA OF A BEETLE (ACILUS); (B) A SPIDER (TEGENARIA)

inferior to the vertebrate eye. Eyes 37 cm. in diameter have been found in the giant cuttlefishes of the genus Architeuthis.

The eyes of turbellarian worms and leeches have a somewhat different structure. In these animals, it is true, eye-cups are present, but they are not formed by the retinal cells themselves, but of pigment cells, which absorb the light, while the sensory cells penetrate into the interior of the cup (fig. 7).

Faceted Eyes.—We find quite a different type in the faceted eyes of insects and crustaceans. As the name implies, the eye may be seen to be formed of a great number of facets, usually square or hexagonal in shape, which in their regularity resemble closely those cut on a precious stone. Each facet corresponds to a single eye or *ommatidium,* which always takes the shape of an elongated cone. In each of these eyes, taken by itself, the following parts may be distinguished. The outermost part consists of a small, somewhat rounded, transparent lens. Under this is the

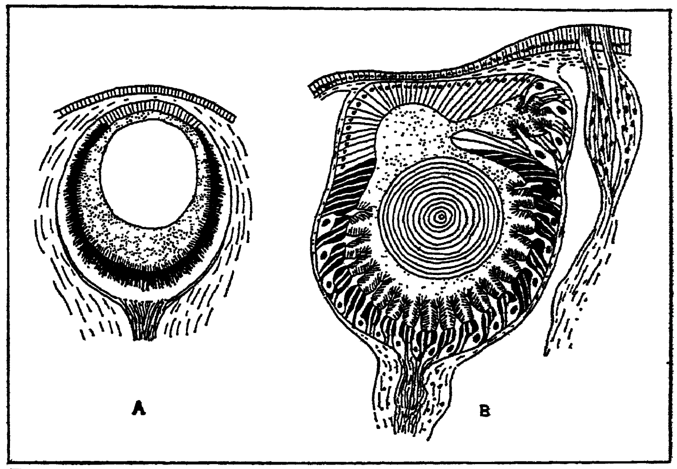

FIG. 5.—CLOSED, VESICULAR EYES OF (A) A MARINE GASTROPOD (MUREX); (B) A LAND GASTROPOD SLUG (LIMAX)

crystalline cone, a conspicuous structure, usually gelatinous, which is quite transparent, and allows the rays of light to pass freely, and directs their path. If we examine the eye of a diurnal insect, we find that the inner extremity of the crystalline cone is adjacent to the cells which, collectively, correspond to our retina. Each ommatidium has only 6 or 7 of these cells. Among them they secrete a remarkable body, the rhabdom, which evidently represents a kind of transformer.

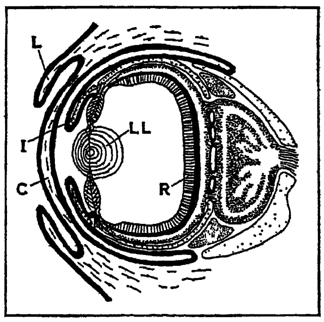

FIG 6.—EYE OF A CUTTLEFISH; L. LID; C. CORNEA; I. IRIS; LL. LENS; R. RETINA

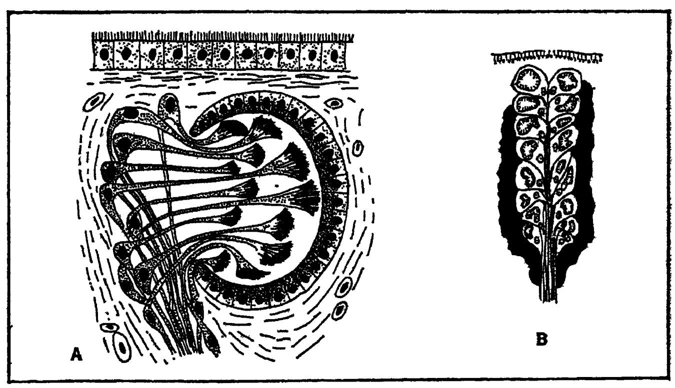
The rays of light which enter the eye are focused on the rhabdom, and there are evidently brought into such a form of energy that they are available to the sensory cells. The nervous layer immediately adjoins the sensory cells. In diurnal insects each ommatidium is separated from its neighbour by a layer of pigment.

Somewhat comprehensive conclusions may be drawn from the structure of the faceted eye as to its functional powers. It seems certain that each ommatidium functions separately. It



AFTER HESSE

FIG. 7.—(A) EYE OF A TURBELLARIAN WORM (PLANARIA): (B) EYE OF A LEECH (HIRUDO)

projects the image of a point of light. The whole image seen thus by an insect is composed only of as many elements as the eye possesses facets. The number of these, however, is surprisingly small. Even those insects which have the best sight, such as dragonflies, have only about 60,000 ommatidia. With this we

must compare the fact that in the vertebrate eye a single sq.mm., which gives only an exceedingly small portion of the whole image, contains about 300,000–700,000 separate elements. It follows as a matter of course that only in a very slight degree is an insect

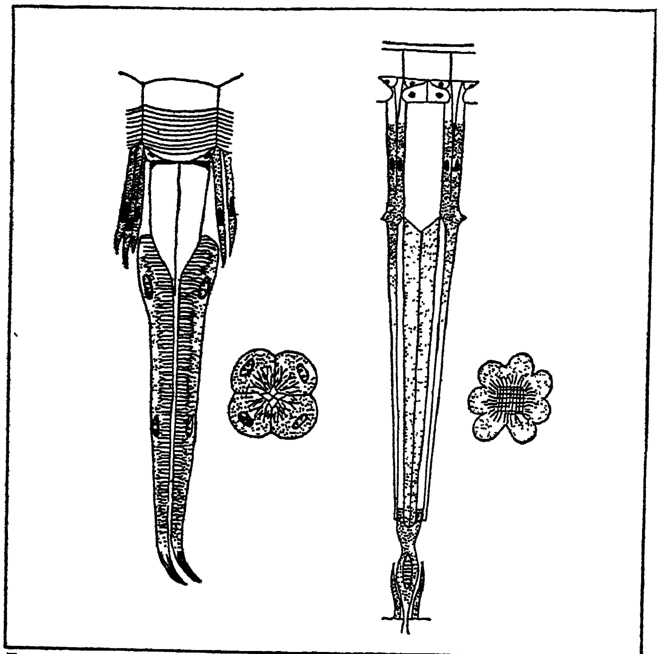


FIG. 8.—(LEFT) OMMATIDIUM FROM THE FACETED EYE OF AN INSECT (COCKROACH, PERIPLANETA) AND CROSS-SECTION THROUGH THE RETINULA. (RIGHT) OMMATIDIUM OF A CRUSTACEAN (CRAYFISH, ASTACUS), WITH CROSS-SECTION THROUGH THE RETINULA

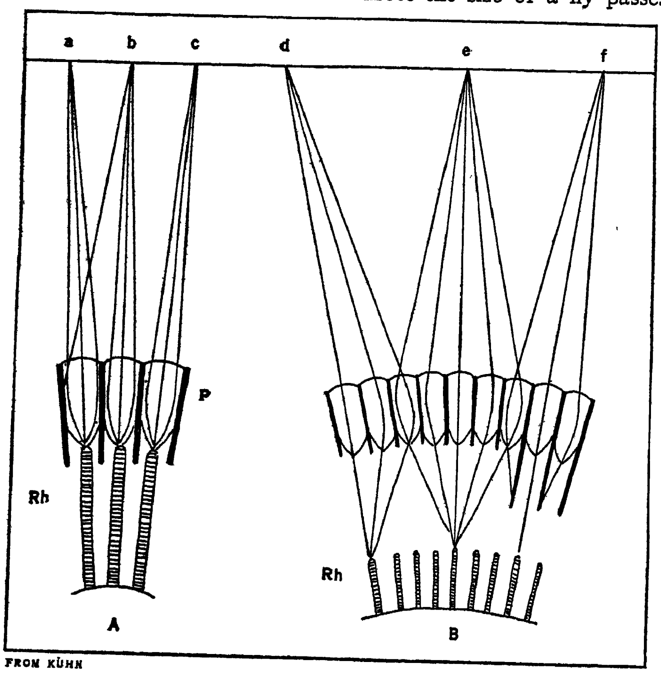
able to distinguish form, as is borne out by the previously mentioned experiments. Most insects, which have only a few thousands or even hundreds of ommatidia, cannot do this at all. On the other hand, these eyes are eminently adapted for the perception of movement. When an insect the size of a fly passes

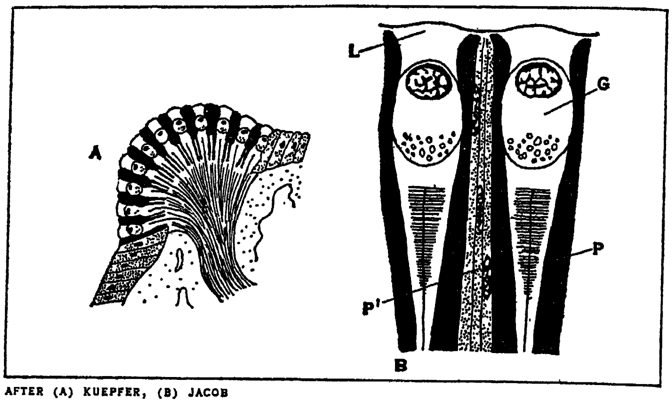


FROM KÜHN

FIG. 9.—PATH OF THE LIGHT-RAYS IN A FACETED EYE: (A) IN ONE GIVING AN APPOSITION-IMAGE, (B) IN ONE GIVING A SUPERPOSITION-IMAGE; P. PIGMENT; RH. RHABDON

in front of a dragonfly at a distance of about 2 metres, it is seen by the latter only as a black point, for it can be proved that, in this case, only one single ommatidium catches the image of the fly. In spite of this it is pursued, captured and eaten.

Eyes of Nocturnal Insects.—The eyes of nocturnal insects and of the mostly nocturnal crustaceans are constructed in a remarkably different manner from those of diurnal insects. As is to be expected, such an eye is constructed so as to admit a greater amount of light than that of a diurnal insect. This is attained by the ommatidia being no longer separated by pigment layers. In addition, the crystalline cone has, in such animals, other physical peculiarities. The physiologist Exner has proved this conclusively for the eyes of the glow-worm. He showed



AFTER (A) KUEPFER, (B) JACOB

FIG. 10.—FACETED EYE FROM THE MARGIN OF THE MANTLE OF THE BIVALVE MOLLUSC ARCA

(A) Transverse section through the edge of the mantle. (B) Two Ommatidia, more strongly magnified. L. Lens. G. Vitreous humour. P. Pigment coat of sensory cell. P' Interstitial pigment cells

that the light given out by a luminous point penetrates not only one ommatidium but many (fig. 9). After leaving the crystalline cone, however, the rays are refracted in such a way that, ultimately, they again become focused upon one point of the retina. Each rhabdom receives, therefore, a much greater amount of light than those in the eyes of diurnal insects. On account of the arrangement one upon the other of the points of light which come from the various crystalline cones, such eyes are described as giving "superposition images," while those of diurnal insects give "apposition images." It is of interest that crustaceans are able to use their eyes either for superposition or for apposition vision, according to their needs. This is attained by the movement of the pigment in the cells which separate the ommatidia.

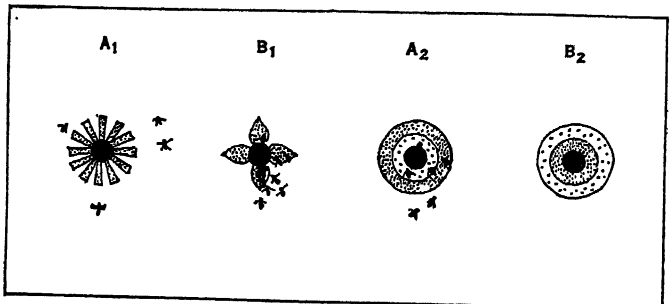


FIG. 11.—TRAINING HONEY-BEES TO DISTINGUISH FORMS

B_1 and A_2 are the boxes with forms to which the bee had been previously trained to come; A_1 and B_2 are other boxes

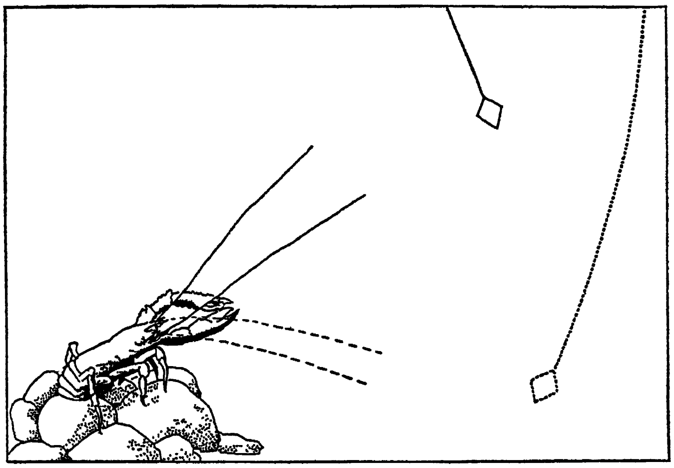
Faceted eyes are found in some bivalves (*Arca*) and Chaetopod worms, as well as in Arthropods, but serve, however, only for perception of movement (fig. 10).

THE FUNCTION OF THE EYE

To man the eye is by far the most important of all the sense organs. With the help of our eyes we recognise our fellow men, animals and plants, the things we use in daily life, in short all the world around us. He who studies the sight of animals is apt to make the mistake of supposing that their eyes function like ours.

Such perception of form as permits us, from the appearance of an object, to draw conclusions as to its other qualities, and thus to understand its nature, is only to be found in the highest animals, mammals, birds, and, perhaps, some reptiles. Even the

frog does not recognise a motionless fly as desirable food, but is quite indifferent to it; it is, so to speak, "intellectually blind." This applies in a still greater degree to the invertebrate or lower animals. Of these, so far as is known at present, only bees and their relatives show a definite sense of form. Von Frisch demonstrated that bees can be trained to distinguish forms. Food was given them in a closed box, into which they were obliged



AFTER DOFLEIN

FIG. 12.—GALATHEA SQUAMOSA, SHOWING REACTION TO OPTICAL PERCEPTION OF AN APPROACHING OBJECT, BY BENDING ANTENNAE DOWN

to crawl through a hole. Around this hole was glued the picture of a flower, while round a hole in another box, which was placed beside the first, but was empty, was gummed the picture of another flower. After food had been given thus for several days, the boxes, which could be distinguished only by the difference in the pictures of the flowers, were placed before the bees empty. A much greater number of visits was paid to the box which had contained food (*see* fig. 11). Bees, therefore, are able to distinguish between two flowers according to their shape. Similar experiments may be made also by using simple geometrical figures.

Perception of Movement.—As far as is known at present, none of the other lower animals are capable of such a performance. It is easy to guess for what purpose they use their eyes if we consider the behaviour of some mammals. The hare takes not the least notice of the sportsman standing motionless at the edge of the wood, but as soon as he makes the slightest movement, it takes to flight. It, therefore, exhibits in a marked degree the power of perception of movement. Spontaneous movement can take place only in living organisms. Since the animal heeds only the movement, and not the motionless form, it is able, in the simplest way, to distinguish between "living" and "lifeless."

The power of perceiving movement is very distributed. Schrader has made interesting experiments with falcons. These intelligent birds, under normal conditions also, are able to distinguish motionless prey as such. If, however, the cerebrum is removed, they notice movement only. A falcon from which the cerebrum has been removed, pursues and strikes a living, active mouse just as skilfully as would a normal bird; as soon as the mouse is dead, however, it takes no more interest in it. In general, frogs and salamanders snap only at moving prey, and every angler knows that fishes act in the same way. Among the lower animals interesting observations have been made on insects, crustaceans and molluscs. The scallop, *Pecten jacobaeus,* has, on the edges of its mantle, a large number of eyes of complex structure. On account of the poor development of its brain, however, it is unable to distinguish its enemies by means of sight, and is able only to perceive movement. If another animal crawls slowly towards it, as soon as the scallop perceives the movement, it extends the long, thread-like tentacles, which are its olfactory organs. By means of these it determines whether the approaching animal is friend or foe. If it be the former, the scallop quickly becomes quiet again; if the latter, it swims away hurriedly. A corresponding co-operation between eyes and feelers is often to be seen in decapod crustaceans. These animals react to a moving object by holding the antennae straight out towards it. (*See* fig. 12.) Uexkuell showed that the house-fly finds its mate by means of this perception of movement. If a small, black bead, about the size of a fly, is fastened to a thread, and drawn fairly rapidly through the air, the male flies immediately throw themselves upon it. If the surface of the bead be smeared with a sticky substance, it makes an ideal fly-trap. That dragonflies and other predatory insects only pursue moving prey need hardly be mentioned.

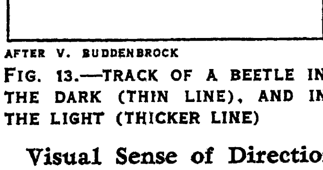
The most lowly animals which undoubtedly possess the power of perceiving movement are certain marine Chaetopod worms (*Branchiomma*). They live in tubes, constructed by themselves, from which only their heads project, which bear numerous, long tentacles. Each tentacle has at its extremity a compound eye. If one makes a rapid movement with the hand in front of the aquarium, every worm retreats into its tube with lightning rapidity. That this is a typical case of the visual perception of movement is proved by the fact that darkness or light, produced by the switching off or on of an electric lamp, without movement, makes no impression whatever upon the animals.

That the lower animals perceive and take heed of motionless objects is really only to be observed when they have to turn aside from their path on account of them. When an insect flies about in a forest it must not run the risk of colliding with every tree. This also applies to the deliberately moving gasteropods.

We can well observe in these slow-moving creatures how skilfully they avoid the obstacles which may be placed in their path. This is also the case if we place between the animals and the obstacle a glass screen, which excludes all impressions of it other than visual ones. We do not know as yet how widespread this "avoiding reaction" is in the animal kingdom. On the other hand, visual perception of direction is almost universal. This power enables the animal to pursue an orderly path in a straight line. It hardly requires to be proved that it is a necessity of life for all freely-moving animals to crawl, fly or swim straight ahead. It suffices to remember that, without this power, an animal runs the risk of moving round and round in circles, in a quite aimless manner. Mephistopheles says in "Faust":—

> I tell you, the man who speculates,
> Is like a beast upon a barren heath,
> Led in a circle by an evil spirit,
> While just beyond are spreading, fresh, green fields.

We can conjure up this evil spirit in our experiments by conducting them in darkness. If we allow small insects to creep about in the dark on a piece of glass lightly smeared with soot, we can see from their tracks that they have crawled here and there, not indeed in circles, but in a totally aimless manner, without moving far from one place (*see* fig. 13). We can increase this restriction of movement by amputating one of the legs of the insect; it then frequently runs in a narrow spiral, always turning towards the same side. As soon as we admit light into the darkened chamber, however, matters are instantly changed; the creature runs away from the light in a course straight as a line.



AFTER V. BUDDENBROCK

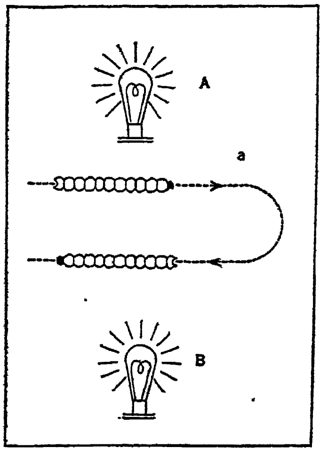
FIG. 13.—TRACK OF A BEETLE IN THE DARK (THIN LINE), AND IN THE LIGHT (THICKER LINE)

Visual Sense of Direction.—These experiments prove the existence of the visual perception of direction. This applies to human beings also. It has long been known that a man in desert or snow covered regions, or in dense brush, unable to use his sight for orientation, moves round in circles, and, after walking for hours, finds himself back at the point from which he started. The manner in which man and the higher animals orientate themselves in space by means of sight is generally known. Quite unconsciously they choose some prominent object, such as a

tree, for which they aim; on approaching this they select as their goal another, more distant object, lying in the same direction.

The lower animals regulate their movements on a different principle. They shape their course in relation to the light.

This method of orientation is well illustrated by the following example. Xenophon frequently writes in his "Anabasis":—"We marched keeping the sun on our right." That is to say, we can in a quite unfamiliar region, travel in a straight course in a particular direction, if we take care that the rays of the sun and the line of march enclose a constant angle. What man does intelligently the lower animals accomplish by blind instinct.



AFTER V. BUDDENBROCK

FIG. 14.—THE MOVEMENTS OF A CATERPILLAR IN RELATION TO LIGHT

The particular motion with relation to the light may be demonstrated experimentally in two ways. A small candle is put on a table in a dark room, and the animal to be studied is placed about half a metre distant from the light. (Some small beetles or caterpillars are good subjects for this experiment.) The animal begins by running past the light, apparently without heeding it; if, however, we suddenly take up the light and place it on the other side of the animal, the latter turns in an angle of 180°, and continues its way in the opposite direction to that previously followed (fig. 14). This very pretty experiment does not succeed with all species. The following is simpler, and can be carried out with all sorts of insects, crustaceans, and gasteropods. The animal is placed on a table near the light, and left to its own devices; it may then be observed that, under the influence of the light which radiates outwards in a circle, the animal performs a circus-movement round the source of illumination. It moves, therefore, in such a way that the angle formed by the light rays and its path remains constant. In this instance the angle is roughly a right angle; the animal is able, however, to change it at will. For example, it may crawl in such a way that the light falls upon its eyes obliquely, from behind; it then moves in a spiral which gradually removes it from the light (*see* fig. 15).

The long known fact that nocturnal insects are attracted by a lighted lamp is connected with this particular type of movement. Usually, on their nocturnal flights, they orientate themselves by the moon, the clouds, or other far distant sources of light. If, however, they come by chance within the influence of a near source of light, such as an electric arc-lamp, they are compelled to fly around the artificial light in circles or in spirals. Often enough they come thus into the immediate neighbourhood of the light, and are burnt.

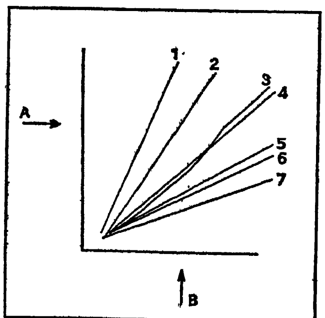
Visual perception of direction in animals may show itself in quite another way, namely, in what is called *phototaxis.*

The following example illustrates what is meant by this. If a bee is taken, and released in the middle of a room, it flies with absolute certainty towards the window, and, therefore, towards the light. Such an animal is called *positively phototactic.* The cockroach illustrates an opposite condition; it is *negatively phototactic.* It avoids the light, and when turned out of its hiding place, it will assuredly make for the dark.

That phototaxis is not always a constant character is shown by the bee. We cannot say off-hand "the bee is positively phototactic." It is so only under quite definite conditions; in very many other circumstances it is not so. For example, when it returns from gathering honey, and flies into the dark hive, it is much rather to be described as negatively phototactic.

Sometimes it is easy to state the conditions under which an animal will become phototactic. The bee becomes positively phototactic if it is caught, and strives to free itself. In nature, where there are no glazed windows, brightness means the open air and the sky. A very clear example of phototaxis appearing only under certain conditions is furnished by the water scorpion (*Nepa cinerea*). This creature lives in shallow waters among the plants on the bottom. It is, however, an air-breather, and is obliged to ascend to the surface of the water from time to time, in order to inhale it. In this it is aided by positive phototaxis, which, in this case, co-operates with negative geotaxis. Since light only enters the water from above, the creature, which becomes phototactic only with lack of air, creeps up the water plants as much as possible in a vertical direction, until it reaches the surface. Scarcely, however, has it breathed in the fresh air, when phototaxis ceases, and the water scorpion is able to descend again into the deeper regions. As a final example, the water-flea, *Daphnia,* may be mentioned, in which we can produce phototaxis at will. We have only to introduce water containing carbon dioxide into a vessel in which there are Daphnia, to see at once that all the animals swim as quickly as possible towards the light. Here, however, we must again make it clear that, normally, the light enters from above. Daphnia live in stagnant waters, frequently very unclean, at the bottom of which poisonous carbon dioxide can be very easily formed through putrefactive processes. In this instance, phototaxis serves to protect the Daphnia from poisoning by carbon dioxide.

The Mechanism of Phototaxis.—While these matters are comparatively simple, the naturalists of the present day are as yet very divided in their opinions regarding the mechanism of phototaxis. There are various theories, of which we may, perhaps, go so far as to say that each is correct in some instances. The best known is the Theory of Tropisms (also called the Ray-Verworn Theory, or the Theory of Tropotaxis). It is founded on the fact that the majority of animals which are prototactic have bilateral symmetry. These all have a median plane dividing the body into two, absolutely identical halves. The entire animal is regarded as a small automaton. The light rays which fall on the eye are converted into nervous energy, which is conducted to the brain. The latter transmits the stimulus to the limbs, which are under its control, and thus, according to this theory, the movements of the legs are, by a natural law, dependant on the strength of the illumination of the eyes. If the rays of light come from the front, they strike both eyes equally, and, therefore, the legs of each side move with equal force, and the animal runs straight forward. If, however, the light comes from one side, so that one eye is more strongly illuminated than the other, there is also a difference between the two sides in the working of the legs. The consequence must be that the animal turns until its median plane coincides with the direction of the light rays. When this is accomplished, it again runs in a straight line towards the light. This theory is so very striking in its great simplicity that, at first, it was received with much enthusiasm, particularly by everyone interested in Natural Philosophy.



AFTER MÜLLER

FIG. 15.—TRACK OF A NEGATIVELY PHOTOTACTIC WOODLOUSE UNDER THE INFLUENCE OF TWO BEAMS OF LIGHT AT RIGHT ANGLES (A & B)

With time, however, the opposition to this theory has been greatly increased, and there are many naturalists who have almost completely relinquished it. Frequently, the law which governs the movements of such animals is known by another name, namely the *"Law of Resultants."* Thus, if we allow an animal to crawl into a field of light which is formed by two crossing beams, it is compelled to move according to the resultant. A fine example of this manner of reaction has been furnished by Frl. Müller, who worked with woodlice (*see* fig. 15). It appears that the animals under the influence of two equally strong beams of light, run exactly in the diagonal; if the beams are made to be of unequal strength the angle alters. It can be

calculated in advance if we know the strength of both beams of light.

A second theory, which is in opposition to the theory of tropisms, asserts that the lower animals behave similarly to man and the higher animals. If a man walks towards a light, or let us say in a general way towards some optically perceptible point, first of all he fixes his eyes on the light, that is to say he moves them so that the light falls on the central point (*fovea centralis*); he then turns his head and body towards the light and goes straight forward. Kuehn has named this kind of reaction "*telotaxis*"; it is fundamentally opposed to tropotaxis, as will appear if we close one eye. A telotactically reacting animal is just as well able to direct its course when using only one eye as when using both; a tropotactically reacting animal, on the other hand, when it has only one eye is compelled continually to move round in circles. It is easy to convince oneself, on the basis of this alternative, that the majority of the more highly developed animals, such as insects or the higher groups of Crustacea, behave for the most part telotactically.

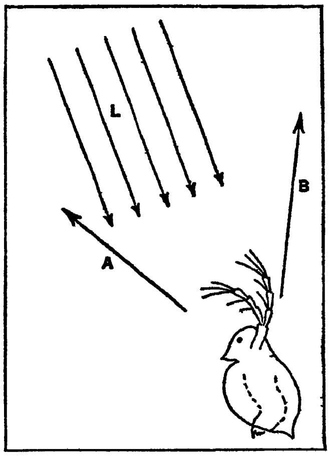


FIG. 16.—UPWARD MOVEMENT OF A POSITIVELY PHOTOTACTIC DAPHNIA, DIAGRAMMATIC

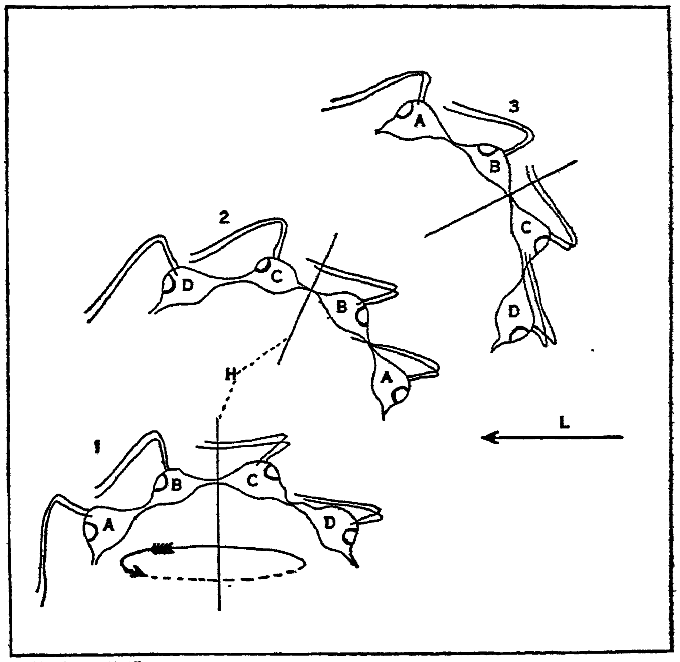
The numerous partial refutations which the theory of tropisms has undergone cannot be given in detail here. Only one particularly important argument can be mentioned. It used to be considered a proof of its validity that animals blind on one side constantly run round in circles. If they are positively phototactic, they continually turn towards the side on which they can see; if they are negatively phototactic they turn towards the blind side. Now, in the first place, this certainly does not apply to all cases. The majority of the higher insects learn very quickly to run straight when they have only one eye. Above all, Mast was able to prove that the animal does not move round in circles involuntarily, as the theory of tropisms would require, but that the animal voluntarily runs round thus, and moves its legs in such a manner as to attain this end. If some of the legs are amputated the remaining ones completely alter their movements, so that, in spite of the totally different locomotor conditions, the circus movement is still possible.

A second argument of general application is as follows:—The naturalist usually makes use of horizontal light in his experiments, which strikes the animal from one side. Only under these artificial conditions is it possible to turn about an axis which lies in the plane of symmetry of the body. Under natural conditions, on the contrary, the light, as far as aquatic animals are concerned, comes always from above. The Daphnia on becoming positively phototactic turns from its former position, not to right or left, but backwards. That it swims in the end towards the light, and not in the direction A or B is impossible to understand on the theory of tropisms (fig. 16).

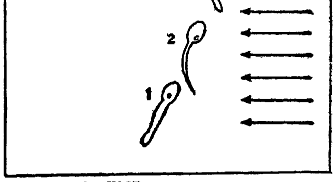
Frequently, however, it is impossible to decide with certainty from such rough experiments the manner in which an animal orientates itself in relation to light, and a closer, more exact analysis is required. We are indebted to S. O. Mast for the best work on this subject. He showed that in many cases, neither tropotaxis nor telotaxis sufficed to account for the phenomena. As the first example we may mention briefly the researches of Mast on the orientation of the colonial Flagellate, *Volvox*. The colony is composed of about 20,000 individuals, which are arranged on the surface. Each zooid has two flagella, and an eye-spot, provided with a lens. The colony has an anterior pole, which is always turned towards the front in swimming, and a longitudinal axis round which it rotates. If a light is placed to one side of a positively phototactic colony, it turns until the anterior pole is directed to the light, and then swims straight towards it. This gives the impression of being a clear case of tropotaxis, but Mast was able to prove that the zooids on the illuminated and on the shaded sides differ, not in the strength of the lashing of the flagella, but in the direction of the strokes. On the former side the flagella lash sideways, on the latter, straight out to the back (*see* fig. 17). It is apparent, therefore, that in this reaction we are dealing neither with a case of tropotaxis nor with one of telotaxis, but with a phenomenon *sui generis*. Very interesting are the orientation movements of



AFTER S. O. MAST

FIG. 17.—PHOTOTACTIC ORIENTATION OF A VOLVOX COLONY, SHOWING ONLY FOUR CELLS. L. THE DIRECTION OF LIGHT

asymmetrical animals, as for example one-eyed animals such as the Ascidian larvae also studied by Mast. These animals are negatively phototactic, and in swimming revolve about their longitudinal axis. When the light comes from one side, the eye, which is set in a pigmented cup, is alternately illuminated and in shadow with each revolution. Every time it is in shadow, the animal makes a stroke with its tail towards the ocular side; every time it is illuminated, it makes a stroke towards the abocular side (*see* fig. 18). In this way the larva quickly turns away from the light.



AFTER S. O. MAST

FIG. 18.—REACTION OF THE NEGATIVELY PHOTOTACTIC, ASYMMETRICAL LARVA OF AMAROUCIUM

We find the least development of the sense of sight in those animals which are unable to perceive either images, movements, or direction, but can only distinguish light and darkness.

They react mostly to alterations in the light intensity to which they are accustomed. A very common phenomenon of this kind is the "shadow reflex." Many of the lower animals, particularly those which dwell in shells or shelters of some kind, into which they can withdraw, do so directly a shadow falls on them.

An animal particularly suitable for the demonstration of this reflex is the vineyard (Roman) snail, *Helix pomatia*, which has a wide distribution in Europe. If we cause a shadow to fall upon its head, it withdraws its horns very quickly, or completely retreats into its shell. Among marine animals may be mentioned

the small sessile crustacean, *Balanus,* which, every time a shadow falls on it, withdraws its feet, which normally move in a constant rhythm. Further, many tubicolous worms react in a similar way, and many bivalves close their shells, if a shadow falls on them.

In short, the phenomenon is unusually widespread. The biological significance of this shadow reflex most certainly is that by this means the animal hides from danger, since the shadow may perhaps indicate the approach of some animal. This is, of course, a very poor expedient, since, in the first place, it fails to give protection from enemies which are in an opposite direction to the sun, and, in the second place, it causes the animal to withdraw unnecessarily thousands of times. Animals which do not possess any well-developed sense organs to give them certain warning of the approach of their enemies, are obliged, however, to help themselves even in this primitive manner.

The animals here mentioned, which respond to the slightest shadow, very frequently do not react in any way if we increase the degree of illumination. Other animals withdraw only in the latter circumstance, and are not disturbed by any shadows. Among these is the sand-dwelling *Mya arenaria,* which is found on the coasts of Europe and America. It lives in the sand at a depth of about 20 cm., and makes a shaft which leads upwards in a vertical direction, in which lies its tubular siphon, the organ by means of which it takes in food and oxygen. If this fleshy siphon were pushed so far out of the shaft that it stretched out into the water, fishes would immediately come and bite it off. The light reflex serves to prevent this; as soon as the siphon pushes out into the water, it is exposed to stronger light, and the reflex movement of withdrawal promptly takes place.

It is just these simple phenomena which are frequently of interest to the naturalist, since by their means we may easily understand the laws which govern the perceptual life of animals, and of mankind also. Weber's Law is very well known. This states that a man is first sensitive to a new stimulus when it stands in a particular numerical ratio to that already present.

Thus, if originally light "L" prevails, an animal sensitive to shadow first withdraws when the light is shaded by about L/20. In this case the value of L is quite immaterial.

The table is compiled from the results of the author's experiments on *Balanus.* L_1 indicates the original light, L_2 the greatest amount of light which yet gives rise to the shadow reflex. L_1/L_2 is, as can be seen, roughly constant.

L_1	L_2	L_1/L_2
1,000	967	1·034
933	875	1·066
750	720	1·0415
500	480	1·0415
250	240	1·0415

From these experiments the fact of *Adaptation* may be proved as a logical inference. The sensitiveness of our eyes is considerably greater in weak light than in strong. The eye thus adapts itself completely to the light conditions present. Starting with an original intensity of 1,000 light units, *Balanus* first reacts when this is diminished by 33 units. With an original intensity of 250 units the animal first notices a diminution by 10 units. On pursuing the subject further, we find that with an original intensity of 25 units, diminution of this by only one unit is noticed by the animals. The eye, therefore, becomes more sensitive as darkness increases.

THE COLOUR-SENSE OF ANIMALS

Colours play such a large part in human life that the question whether animals also possess a sense of colour is of extreme interest to us. In speaking of the colour-sense of animals it behoves us to make it perfectly clear at the outset that it is quite impossible for us to study the sensations of animals. We cannot even say anything about the sensations experienced by our fellow men. On the other hand, we can decide objectively whether an animal is able to distinguish different colours.

The investigation of the colour-sense of animals has followed a remarkably zig-zag course. In the time of Darwin man, almost universally, was convinced that the lower organisms also possessed a sense of colour similar to his own. Later we went to the opposite extreme. Hess pronounced the definite opinion that all invertebrates and fishes were totally colour-blind, and that only the highest organisms, such as mammals, birds, reptiles and amphibians, were able to enjoy the colours of nature. This sweeping generalisation was contradicted, and so gave rise to a very active investigation of the whole subject. The result of these labours may be summarised thus:—very many of the lower animals, such as cuttlefishes, insects and the higher Crustacea, do indeed possess a sense of colour. Further, in cases in which it has not yet been proved to exist we hesitate to draw the conclusion that it is absent.

Experiments.—The methods by which we have sought to investigate the colour-sense in various animals are very numerous. All animals which possess a certain amount of intelligence can be trained to distinguish a particular colour. v. Frisch was the first to attempt this, with bees. It is just in dealing with these insects, for which the array of colours in flowers would seem to have been evolved, that this statement by Hess must give cause for reflection.

In order to understand the following it is necessary to consider more precisely the nature of coloured light. In this two factors are always to be distinguished, the brightness of the light, in physical terms, the intensity, and the colour of the light, or in physical terms its wave-length. In studying the colour-sense of animals we are concerned only with the question whether they are able to distinguish light of different wave-lengths, and we have to take the greatest care, therefore, that the reactions of the animals are not connected with differences in the intensity of the light. v. Frisch made use of the "chess-board" method. On a square board were fixed a large number of pieces of cardboard of all shades of grey, from the lightest white-grey to the darkest black-grey. Among these was placed a piece of cardboard of the colour on which the bees had been trained (blue). If the bees had no sense of colour, but distinguished between the different pieces of cardboard only by their degree of brightness, they would confuse the blue with one or other of the greys, one of which would certainly be of the same tone. If, on the other hand, they had a true colour-sense, such confusion would not occur. The result of the experiment was in favour of the possession of such a sense by the bees. The trained bees, having been accustomed to find their food on a blue background, flew to the blue pieces of cardboard only, and paid no attention to any of the others.

Since these fundamental researches were made by v. Frisch, the colour-sense of bees has been studied with much finer technique, particularly by Kuehn. Above all, we have learnt to train these insects to distinguish the pure colours of the spectrum. We are now able, therefore, to form a fairly precise estimation of the colour-sense of these insects. Bees perceive all wave-lengths between 650–313 $\mu\mu$. Within this range they distinguish four different colours. The first comprises wave-lengths from 650 to about 500 $\mu\mu$, and includes our red of shorter wave-length, and also yellow and green. Seemingly, all these appear to them as one colour. On the other hand, the red of longer wave-length, which we use in our photographic dark-rooms, bees do not distinguish at all; they confuse it with black. The second comprises wave-lengths from 500–480 $\mu\mu$ and corresponds to our blue-green, the third lies between 480 and 400 (our blue and violet). Lastly, bees perceive a fourth visual region in the ultra-violet, which is beyond our powers of sight.

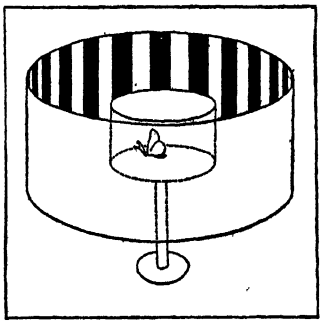
It lies between 400–310 $\mu\mu$. Bees may therefore be trained to distinguish ultra-violet just as well as blue or yellow.

A sense of colour has been proved to exist also in Lepidoptera, dragonflies and flies; perhaps it is universal among insects.

We have gone to work in quite a different manner to prove the existence of a colour-sense in Crustacea. Some of these possess the remarkable power of matching their colouration to that of the surface on which they live. On light backgrounds they are light, on dark ones they are dark. This is brought about by means of particular pigment cells (chromatophors) which are present everywhere beneath the transparent cuticle. The majority

of species have several kinds of chromatophores of different colours. *Crangon,* the species which up to the present has been studied most, has white, yellow, red and black. Stimulation takes place through the eyes; blind crustaceans are no longer able to mimic their background. The light stimuli which reach the eye are communicated to the brain, and by this are transmitted to the pigment cells in a way which we do not yet understand more exactly. Koller was able to prove that the chromatophores which expand are always those which conform in colour to the background. On a grey ground the black cells expand, on a yellow ground, the yellow cells, and on a red ground the red cells. The intensity of the light plays as unimportant a part as in the case of bees.

With the simple inquiry whether a given animal is able to see or distinguish between colours the problem of the colour-sense of animals is by no means exhausted. It can be proved that every organism, including man himself, responds differently to light and its colours, according to the conditions under which it finds itself. According to Schlieper's investigations, in the optomotor reactions about to be described, all the animals studied hitherto act as if they were colour-blind, even those in which a sense of colour has been proved beyond all doubt, either by the "training method" or in some other way. The best-known instance of such a reaction occurring in everyday life is what is called "railroad nystagmus." If we watch a person opposite us in a railway carriage who is looking out of the window, we notice that his eyes do not remain still. They seek to follow the images of the rapidly passing landscape, and move in the direction opposite to that in which the train is going. They are directed forwards again in a particular rhythm. When studying animals we can represent the railway by a rotating cylinder, in the middle of which is placed the animal under observation. The inside of the rotating cylinder has vertical strips of paper stuck on it, of which half are coloured and half grey (fig. 19). Every animal must be studied in relation to a whole series of such cylinders, which differ from one another in the shades of grey, while the coloured strips are the same in all of them. The individual animals react differently to the rotation. Some move the head, some the feelers, some the eyes. In every species, however, a particular combination of grey and colour can be found to which no movement-reaction takes place. This means that, in this instance, the animal perceives no difference between the grey and the coloured strips; it sees a uniform grey, and is thus, in this experiment, certainly as blind to colours as in the previously described experiments it was aware of them. The reaction to the other "grey and coloured" combinations is only to the different degrees of brightness of the strips, not to perception of the colour contrast. The following little table may make this clear; it is taken from the results of experiments with the common white butterfly, *Pieris brassicae,* using the colour "blue." Grey 1 is the lightest, 12 is the darkest; the measured angle is that described by the feelers of the captive insect.



AFTER SCHLIEPER

FIG. 19.—OPTOMOTOR REACTION IN BUTTERFLIES AND MOTHS

Shades of grey	Angle
1	10–15°
3	5°
4 and 5	0°
6	3°
8	10–15°
10	15–20°
12	25°

From these results emerges the startling fact, which has not yet been explained, that the same animal reacts sometimes as if perceiving colours, at others as if colour-blind.

Another important result can be obtained by the methods used by Schlieper. By comparison with the grey papers, of known numerical degrees of brightness, we can calculate the relative brightness which different colours possess for the individual animals. We then reach the remarkable result that this value for the whole of the animal kingdom corresponds to that which prevails in totally colour-blind human beings. This had already been affirmed by Hess, but not sufficient heed was paid to it.

(W. v. BUD.)

SIGHTS. It is a matter of common experience that, owing to the curvature of trajectories, it is necessary in order to propel a missile to any considerable distance, to throw it upward as well as forward, or, to use the technical term, to give it elevation. It is also well known that the trajectories of artillery projectiles fired from rifled guns have in addition a slight curvature in the horizontal plane known as drift. These considerations are discussed quantitatively in the article BALLISTICS and it is there shown how to calculate the elevation and drift correction necessary in any particular case. The process of pointing the gun in the proper direction and giving it the proper elevation is known as laying the gun. Sights are the mechanical devices employed to facilitate accurate laying. Before going on to any detailed discussion of sights it will be convenient here to give definitions of the various technical terms employed in sighting:—

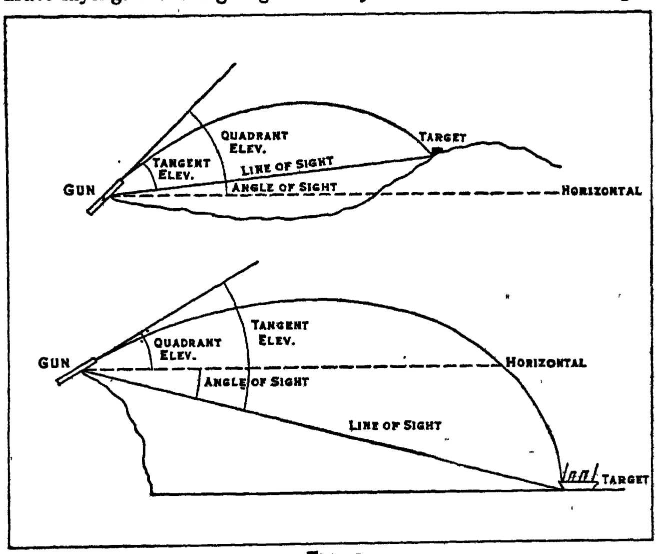

FIG. 1

Line of Fire—The horizontal direction of the target from the gun.

Line of Sight—The line joining gun and target.

Angle of Sight—The angle between the line of sight and the horizontal plane through the gun.

Axis of the Sight—The line joining the hind sight to the fore sight. In the case of telescopic sights, the sight axis is the optical axis of the telescope.

Elevation—The angle the axis of the gun is elevated above some line of reference; in particular, quadrant elevation is the angle between the axis of the gun and the horizontal plane, while tangent elevation is the angle between the axis of the gun and the line of sight.

The process of laying is best considered under two distinct headings (a) laying for line, or direction (b) laying for elevation.

In the earliest days of smooth-bore cannon and short ranges, laying for line was achieved by looking along the top of the gun and laying for elevation was neglected, the range being so short that it was sufficiently accurate to lay the gun along the line of sight (known as point-blank fire). The earliest pattern of sight used in laying for elevation was the tangent scale and foresight, and this is still the arrangement used for the sighting of rifles and machine guns.

The principle can easily be seen from fig. 2. The clamp is

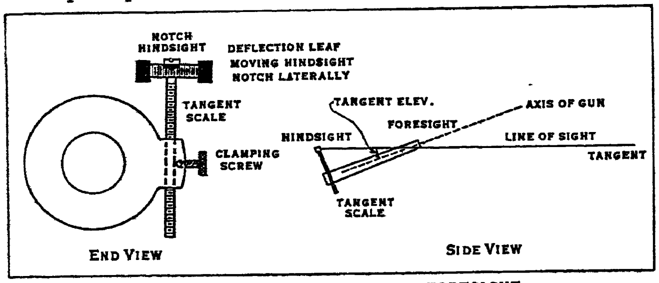

FIG. 2.—TANGENT SCALE AND FORESIGHT

loosened and the tangent bar raised by an amount varying with the desired range. To bring the notch on the tangent scale, the foresight and the target into line it is necessary to elevate the gun and the amount of elevation will depend on the amount the tangent scale has been raised. Thus the graduations on the tangent scale can be marked with the number of yards corresponding to the range realized by that particular elevation. It will be seen that the fundamental principle is that of establishing an angle between the axis of the sight and the axis of the gun, then bringing the axis of the sight to point at the target thus elevating the gun above the line of sight. Since in this case the line of sight is taken as the line of reference, laying is by tangent elevation.

Practically all modern sights are based on this principle, the chief developments being the use of a telescope mounted on a rocking bar (fig. 3) in lieu of the notch and foresight and the mounting of the sight as a whole on some non-recoiling part of the carriage instead of on the gun itself. This latter development, rendered possible by the introduction of mountings in which the gun recoils axially in a cradle, has led to increased rates of fire and also to the use of accurate optical and mechanical systems which could not have withstood the stresses experienced by any form of sight mounted on the gun itself.

Laying for Line.—A brief consideration of the factors affecting laying for line will indicate the requirements to be fulfilled by any satisfactory sight. (i.) Obtaining the line of fire. This consists in pointing the gun in the direction of the target by

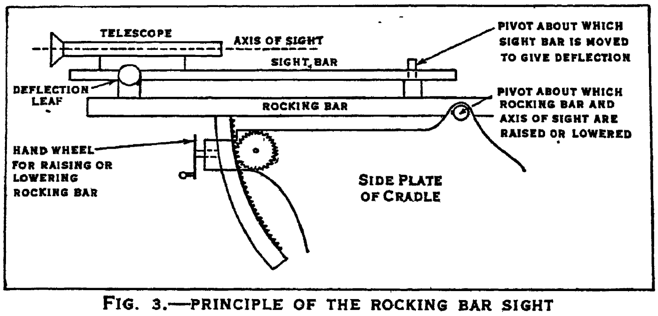

FIG. 3.—PRINCIPLE OF THE ROCKING BAR SIGHT

swinging the mounting as a whole in the horizontal plane. If the target is visible from the gun, this can be done by direct laying through a telescope mounted with its axis parallel to that of the gun. If the target is not visible from the gun, it will be necessary to get the gun in the line of fire by turning it through a calculated angle from the line to some object visible from the gun. A telescope movable about a vertical axis on which is mounted a horizontal circular disc graduated in degrees solves the fundamental part of the problem and is the basis of the panoramic or dial sight, described in the next section (fig. 6). (ii.) Corrections for wind, travel of target, etc. Having got the gun in the line of fire it will be necessary to apply minor corrections, called deflections, to compensate for the above effects. This can be done by mounting the telescope so that it can be moved in a horizontal plane right or left of the line of fire. A typical arrangement is that shown in the rocking bar sight (fig. 3). (iii.) Correction for drift. The deviation due to drift (*see* BALLISTICS) necessitates a correction varying with the range, and since it can be calculated beforehand it should, if possible, be set on the sight automatically. This can be done by means of a cam, or better, as follows:—

It can be shown that the angular deviation due to drift is, in all cases, approximately proportional to the tangent of the angle of elevation. On this basis a correction can be applied with sufficient accuracy by tilting the sight and applying the elevation at a small angle to the vertical (fig. 4). (iv.) Correction for tilt of trunnion axis or want of level of mounting. If the axis about which the gun is elevated is not truly horizontal the act of elevating will also swing the gun to the right or left, necessitating in consequence a correction for line. This error can be corrected by giving a deflection correction the amount of which must be calculated from the measured value of the tilt, but in most modern equipments the correction is made automatically by means of what is known as the oscillating bracket. Briefly the principle is as follows:—The sighting arrangements are mounted on a bracket which can be rotated ("cross-levelling") about an axis parallel to the axis of the gun—before laying for line the whole of the sighting arrangement is corrected for tilt by a cross-levelling screw and spirit bubble.

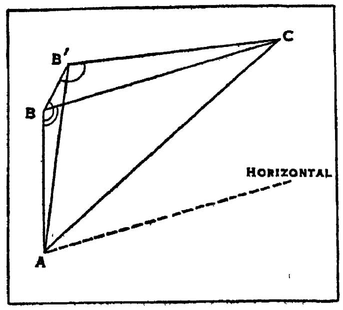

FIG. 4.—CORRECTION FOR DRIFT BY TILTING SIGHT

Laying for Elevation.—The angle of elevation can be given to the gun as quadrant elevation or tangent elevation. The basis of laying by quadrant elevation is the establishment of a given angle between the axis of the gun and the horizontal. This can be done by the use of a clinometer or similar instrument, or by attaching to some fixed part of the mounting a plate graduated in degrees, and arranging for a pointer to be geared to the elevating mechanism so as to indicate the angle through which the gun has been elevated. In some patterns, the pointer is fixed and the dial is rotated by the gearing.

Laying by tangent elevation necessitates mechanical devices for pointing the sights used for laying for line direct at the target,

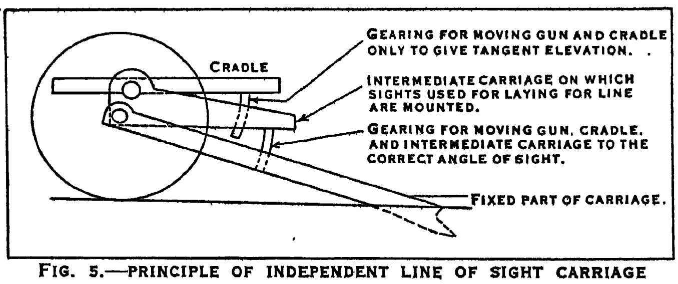

FIG. 5.—PRINCIPLE OF INDEPENDENT LINE OF SIGHT CARRIAGE

thus giving the correct angle of sight, and for elevating the gun through a further angle equal to the desired tangent elevation.

Independent Line of Sight.—The arrangement outlined above for giving tangent elevation has developed in modern light field equipments into the mounting known as the independent line of sight. It consists (fig. 5) of the introduction of an intermediate carriage between the carriage proper and the gun and cradle. One elevating mechanism elevates or depresses the gun and the intermediate carriage, on which the sights used for laying for line are mounted. This enables both gun and sights to be brought to the correct angle of sight. A second elevating mechanism is provided for elevating the gun and cradle only, and is used to establish the correct tangent elevation between the axis of the gun and the axis of the sight.

An arrangement of this nature permits of alterations in range without throwing the sights off the target. For this reason it was introduced into the British service for light field artillery, where one of the essentials is rapidity of fire—one layer can lay on the target continuously while the other puts on correction to tangent elevation. It should be noted that with the independent line of sight the axis of the sight bracket is not parallel to the axis of the

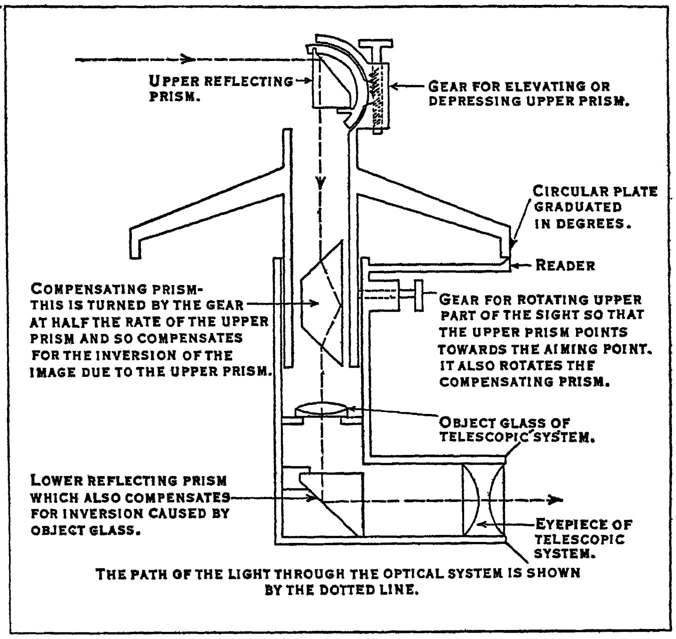

FIG. 6.—DIAL OR PANORAMIC SIGHT

gun (since the sights are mounted on the intermediate carriage, not on the cradle) so that corrections for drift cannot be made by tilt of sight, nor can want of level of mounting be corrected for by cross-levelling the sight. In guns fitted with the independent line of sight mounting, drift is usually corrected for by tilting the trunnion axis. The foregoing are the general principles and methods adopted in the design of sights.

Sights for Mobile Artillery.—The almost universal practice is to provide a dial or panoramic sight for laying for line; the principle of the arrangement can be seen from fig. 6.

With light artillery a common practice in laying for elevation is to use a mounting with the independent line of sight, drift being corrected for by tilt of trunnions. In the latest British equipments the two gears on the carriage are not entirely independent and the mounting is known as the "semi-independent line of sight" mounting. Cross levelling gear is provided and a means of correcting for drift is incorporated in the range gear. With medium and heavy mobile artillery oscillating sights of the rocking bar type are used. The arrangement of such a sight is shown diagrammatically in fig. 7.

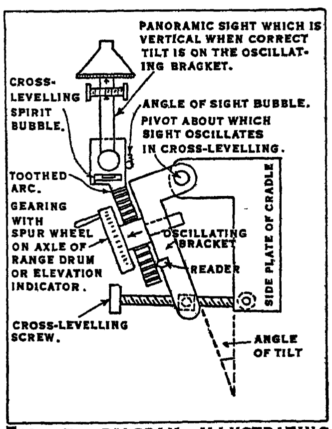

FIG. 7.—DIAGRAM ILLUSTRATING PRINCIPLE OF OSCILLATING SIGHT

In this type the dial sight is connected to a toothed arc which gears with an elevation indicator on the oscillating bracket. The arc is slightly tilted with respect to the sight to compensate for drift as elevation is applied. The dial sight carries an adjustable bubble, by means of which the angle of sight is applied, and also a bubble for cross-levelling the sight.

Sights for Fixed Artillery (Coast Defence).—In fixed coast defence mountings the design of sights is simplified by the following facts:—

(1) The mounting has been made level and therefore no method of correcting for tilt of mounting need be incorporated. (2) Economy of weight and space is not so important as in mobile mountings. (3) Each gun being at a constant (except for rise and fall of tide) height above sea level, the angle of sight at once determines the range (see description of Depression Range Finders in article RANGE-FINDERS). (4) Direct laying for line can almost always be used.

Laying for line being direct a telescope mounted as in fig. 3 solves the problem, and also permits of the application of deflection for wind, travel of target, etc. Laying for elevation is usually by quadrant elevation and a geared elevation indicator graduated in yards. This constitutes the normal method of conducting fire with the medium and heavy natures. An alternative method is that by which the gun is given quadrant elevation by elevation indicator and is directed for line by giving it a bearing from true north. This method of control can be conducted from a distant

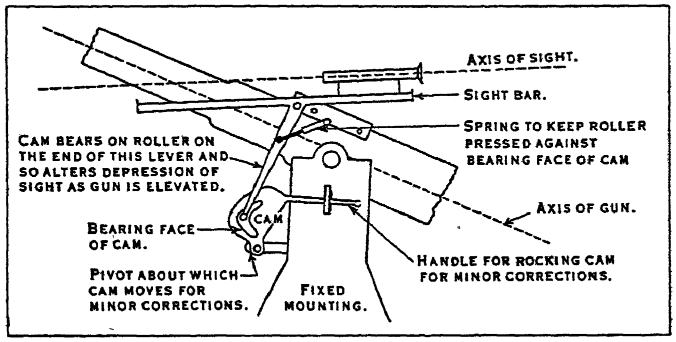

FIG. 8.—PRINCIPLE OF THE AUTOMATIC SIGHT

control post by means of position-finding instruments (*see* article RANGE-FINDERS) and is in most respects similar to central fire-control methods used in battleships.

With the lighter natures of coast artillery, the role of which is to deal with fast-moving torpedo craft, rapidity of fire is essential and the layer should be able to lay and control his gun with as much ease as a rifleman does his weapon. This can be affected by means of the automatic sight which makes use of the fact, stated above, that for each gun the angle of sight determines the range and therefore it is possible so to interconnect gun and sight that when the sight is pointing at the target, the gun has the correct line and elevation. Fig. 8 shows the general arrangement of an automatic sight.

Sights for Anti-Aircraft Artillery.—When firing at aircraft, it becomes necessary to ensure not only that the trajectory passes through the target, but also that the shell will burst at that point. Time-fuzes are used for bursting the shell and the problem of laying now is to give correct line, elevation and fuze-length. Further, the high speeds of modern aircraft make travel deflections no longer minor corrections and, as the target now moves at considerable and varying heights above the gun, change of angle of sight has also to be taken into account. Thus in this branch of artillery work sights will have to be designed so as to permit of two types of deflection—vertical deflection, due to change in angle of sight and lateral deflection, due to travel of target across the front of the gun. The laying arrangements will, in addition, have to provide some interconnection between fuze and elevation used.

The methods of laying fall into two divisions:—

(1) Control from a central post.
(2) Laying at the gun.

Control from a Central Post corresponds to central control in battleship. Some predicting instrument observes the target, selects some point on its course, predicts the time it will arrive there, passes the necessary quadrant elevation, bearing, and fuze to the gun which is laid by indicator just as in the corresponding case in coast defence—in this case no sight arrangements other than the indicators are necessary.

In laying at the gun sights of the oscillating type are used. Angle of sight is obtained by direct observation of the target. Predicting instruments give the necessary deflections which are

put on the sights, the sights being kept pointed at the target; this results in the gun being laid on the position at which the target is to be hit, known as the future position. The fuze having been ordered the layer now gives tangent elevation to the gun till a pointer cuts the corresponding fuze-line on a dial geared to the elevating mechanism. The gun is now at the correct tangent elevation. The process is continuous as the

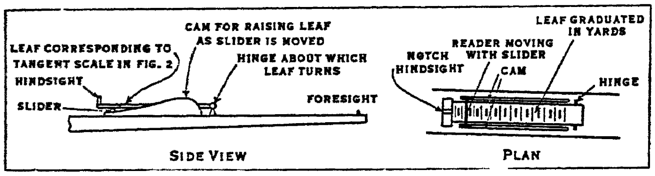

FIG. 9.—ARRANGEMENT OF RIFLE SIGHT

angle of sight is constantly changing and the layer for elevation has to keep on altering his elevation so as to keep the pointer on the fuze line corresponding to the fuze loaded in the gun.

Rifles and Machine Guns.—The sights used for this class of weapon vary very little throughout the world. Except for special purposes, telescopic sights are not used. The type is the tangent sight, consisting of a fixed fore-sight near the muzzle and a hind-sight (notch or aperture) movable in a vertical plane usually by swinging about a horizontal axis fixed transversely to the barrel. This swinging leaf takes the place of the tangent scale in fig. 2.

(G. O. C. P.; A. V. K.)

SIGHT-SINGING. The statement has often been made that in Tudor times ability to sing at sight was regarded as an accomplishment which should be possessed by every educated person. To what extent this ideal was actually realized is no doubt another matter—certainly it must have been confined to a comparatively small section of society and must have been still further limited by the scarcity of printed music. The people no doubt sang their folk songs, but these were acquired by ear.

About the middle of the last century, John Hullah (*q.v.*), an English musician seeking a method of singing from notation, turned to the Continent for inspiration, and established in Great Britain a system of teaching sight-singing, based on the principle of a fixed tonic. About the same time, John Curwen, an English Non-conformist minister, developing a method of teaching and training devised by a Miss Glover, evolved what is known as the tonic sol-fa system. This system employed not a fixed but a movable tonic, and for a time controversy ran high between the rival schools. The fixed-doh method had, however, one serious weakness, for it pre-supposed on the part of the singer a sense of absolute pitch, which is possessed by very few, and the system of a movable tonic, with its strong appeal to the perception of relative pitch, which can be cultivated in all save the aurally defective, has consequently almost completely superseded, at all events throughout the English-speaking world, the older method.

On the continent of Europe sight-singing instruction is still mostly based on a fixed tonic, though considerable attention has been given in France to a method evolved by Chevé (1850), which is based on a movable tonic, and which uses numbers instead of names for the degrees of the scale. In the United States the general method of teaching sight-singing is that based on a direct application of a movable tonic to staff notation.

SIGIRI, the Lion's Rock, the ruin of a remarkable stronghold 7° 59′ N., and 81° E., 14 m. N.E. of Dambulla, and about 17 m. W. of Pulasti-pura, the now ruined ancient capital of Ceylon. There a solitary pillar of granite rock rises to a great height out of the plain, and the top actually overhangs the sides. On the summit of this pencil of rock there are five or six acres of ground; and on them, in A.D. 477, Kasyapa the Parricide built his palace, and thought to find an inaccessible refuge from his enemies. His father Dhatu Sena carried to completion, among other good works, an ambitious irrigation scheme—probably the greatest feat of engineering that had then been accomplished anywhere in the world. This was the celebrated Kala Wewa, or Black Reservoir, more than 50 m. in circumference. The fresco paintings in the galleries are the most interesting of the extant remains. They are older than any others found in India, and have been carefully copied, and, as far as possible, preserved.

See H. C. P. Bell, *Archaeological Reports* (Colombo, 1892–1906); H. W. Cave, *Ruined Cities of Ceylon* (London, 1906).

SIGISMUND (1368–1437), Roman emperor and king of Hungary and Bohemia, was a son of the emperor Charles IV. and Elizabeth, daughter of Bogislaus V., duke of Pomerania. He was born on Feb. 15, 1368, and in 1374 was betrothed to Maria, the eldest daughter of Louis the Great, king of Poland and Hungary. Having become margrave of Brandenburg on his father's death in 1378, he was educated at the Hungarian court from his eleventh to his sixteenth year, and was entirely devoted to his adopted country. His wife Maria, to whom he was married in 1385, was captured by the rebellious Horvathys in the following year, and only rescued with the aid of the Venetians in June 1387. Sigismund had been crowned king of Hungary on March 31, 1387, and having raised money by pledging Brandenburg to his cousin Jobst, margrave of Moravia, he was engaged for the next nine years in a ceaseless struggle for the possession of this unstable throne. (*See* HUNGARY.)

In 1396 Sigismund led the combined armies of Christendom against the Turks, who had taken advantage of the temporary helplessness of Hungary to extend their dominion to the banks of the Danube. This crusade, preached by Pope Boniface IX., was very popular in Hungary. The nobles flocked in thousands to the royal standard, and were reinforced by volunteers from nearly every part of Europe, the most important contingent being that of the French led by John, duke of Nevers, son of Philip II., duke of Burgundy. After capturing Widdin, he sat down before the fortress of Nicopolis, to retain which Sultan Bajazid raised the siege of Constantinople, and at the head of 140,000 men completely overthrew the Christian forces (Sept. 25–28, 1396). Deprived of his authority in Hungary, Sigismund then turned his attention to securing the succession in Germany and Bohemia, and was recognized by his childless step-brother Wenceslaus as vicar-general of the whole empire. But on the deposition of Wenceslaus (1400) Rupert III., elector palatine of the Rhine, was elected German king in his stead. Sigismund was involved in domestic difficulties out of which sprang a second war with Ladislaus of Naples; and on his return to Hungary in 1401 he was once imprisoned and twice deposed. This struggle in its turn led to a war with Venice, as Ladislaus before departing to his own land had sold the Dalmatian cities to the Venetians for 100,000 ducats. In 1401 Sigismund assisted a rising against Wenceslaus, during the course of which the German and Bohemian king was made a prisoner, and Sigismund ruled Bohemia for nineteen months. In 1410 the German king Rupert died, when Sigismund, ignoring his step-brother's title, was chosen German king, or king of the Romans, first by three of the electors on Sept. 20, 1410, and again after the death of his rival, Jobst of Moravia, on July 21, 1411; but his coronation was deferred until Nov. 8, 1414, when it took place at Aix-la-Chapelle.

During a visit to Italy the king had obtained from John XXIII. a promise that a council should be called to Constance in 1414. He took a leading part in the deliberations of this assembly, and during the sittings made a journey into France, England and Burgundy in a vain attempt to secure the abdication of the three rival popes. (*See* CONSTANCE, COUNCIL OF.) The complicity of Sigismund in the death of John Huss is a matter of controversy. He had granted him a safe-conduct and protested against his imprisonment; and it was during his absence that the reformer was burned. An alliance with England against France, and an attempt to secure peace in Germany by a league of the towns, which failed owing to the hostility of the princes, were the main secular proceedings of these years. In 1419 the death of Wenceslaus left Sigismund titular king of Bohemia, but he had to wait for seventeen years before the Czechs would acknowledge him. But although the two dignities of king of the Romans and king of Bohemia added considerably to his importance, and indeed made him the nominal head of Christendom, they financially embarrassed him. It was only as king of Hungary that he had succeeded in establishing his authority and in doing anything for the order and good government of the land. Entrusting the gov-

ernment of Bohemia to Sophia, the widow of Wenceslaus, he hastened into Hungary; but the Bohemians, who distrusted him as the betrayer of Huss, were soon in arms; and the flame was fanned when Sigismund declared his intention of prosecuting the war against heretics who were also communists. Three campaigns against the Hussites ended in disaster; the Turks were again attacking Hungary; and the king, unable to obtain support from the German princes, was powerless in Bohemia. His attempts at the diet of Nuremberg in 1422 to raise a mercenary army were foiled by the resistance of the towns; and in 1424 the electors, among whom was Sigismund's former ally, Frederick I. of Hohenzollern, margrave of Brandenburg, sought to strengthen their own authority at the expense of the king. Although the scheme failed, the danger to Germany from the Hussites led to fresh proposals, the result of which was that Sigismund was virtually deprived of the leadership of the war and the headship of Germany. In 1431 he went to Milan where on Nov. 25, he received the Lombard crown; after which he remained for some time at Siena, negotiating for his coronation as emperor and for the recognition of the Council of Basel by Pope Eugenius IV. He was crowned emperor at Rome on May 31, 1433, and after obtaining his demands from the pope returned to Bohemia, where he was recognized as king in 1436, though his power was little more than nominal. On Dec. 9, 1437 he died at Znaim, and was buried at Grosswardein. By his second wife, Barbara of Cilli, he left an only daughter, Elizabeth, who was married to Albert V., duke of Austria, afterwards the German king Albert II., whom he named as his successor. As he left no sons the house of Luxemburg became extinct on his death.

Sigismund was one of the most far-seeing statesmen of his day, and steadily endeavoured to bring about the expulsion of the Turks from Europe by uniting Christendom against them. As king of Hungary he approved himself a born political reformer, and the military measures which he adopted in that country enabled the kingdom to hold its own against the Turks for nearly a hundred years. His sense of justice and honour was slight; but as regards the death of Huss he had to choose between condoning the act and allowing the council to break up without result.

Jahrhundert* (Berlin, 1897); E. Windecke, *Denkwürdigkeiten zur Geschichte des Zeitalters Kaisers Sigmund* (Berlin, 1893), and *Das Leben Königs Siegmund* (Berlin, 1886); J. Aschbach, *Geschichte Kaiser Sigmunds* (Hamburg, 1838–45); W. Berger, *Johannes Hus und König Sigmund* (Augsburg, 1871); G. Schönherr, *The Inheritors of the House of Anjou* (Buda-Pesth, 1895); and J. Acsády, *History of the Hungarian Realm*, vol. i. (Buda-Pesth, 1903). Of the German books Aschbach is the fullest, and Windecke the most critical. Schönherr is the best Hungarian authority. Acsády is too indulgent to the vices of Sigismund. *See* also A. Main, *The Emperor Sigismund* (1903).

SIGISMUND I. (1467–1548), king of Poland, the fifth son of Casimir IV. and Elizabeth of Austria, was elected grand-duke of Lithuania on Oct. 21, 1505 and king of Poland on Jan. 8, 1506. He had served his apprenticeship in the art of government first as prince of Glogau and subsequently as governor of Silesia and margrave of Lusatia under his elder brother Wladislaus of Bohemia and Hungary. His little principality of Glogau soon became famous as a model state, in the prevailing anarchy of waning principalities, and as governor of Silesia he suppressed the robber knights with an iron hand, protected the law-abiding classes, and revived commerce. In Poland his first step was to recover control of the mint, and place it in the hands of capable middle-class merchants and bankers, like Caspar Beer, Jan Thurzo, Jan Boner, the Betmans, who reformed the currency and opened out new ways for trade and commerce. In foreign affairs Sigismund was largely guided by the Laskis (Adam, Jan and Hieronymus), Jan Tarnowski and others, most of whom he selected himself. His first wife, whom he married in Feb. 1512, was Barbara Zapolya, daughter of Stephen Zapolya of Hungary. On Barbara's death three years later without male offspring, Sigismund (in April 1518) married the beautiful and wealthy Bona Sforza, a kinswoman of the emperor and granddaughter of the king of Aragon, who used her great financial and economic talents almost entirely for her own benefit, corrupted society, degraded the clergy, and became universally detested.

During the first twenty years of his reign, Sigismund was almost incessantly at war with Muscovy. The Tatars too, ravaged the border with a frequency which ultimately led to the establishment of the Cossacks. (*See* Poland: *History*.) Protracted quarrels, again, with the grand-masters of the Teutonic Order, who were anxious to shake off Polish suzerainty led to a war in 1520–21, but were composed in 1525 when the last grand-master professed Lutheranism and as first duke of Prussia did public homage to the Polish king in the market-place of Cracow.

Personally a devout Catholic, Sigismund was nevertheless too wise and just to permit the persecution of non-Catholics; and in Lithuania, where a fanatical Catholic minority of magnates dominated the senate, he resolutely upheld the rights of his Orthodox subjects, and protected the Jews.

After his 60th year there was a visible decline in Sigismund's energy and capacity. His gigantic strength and herculean build lent him the outward appearance of health and vigour, but during the last two-and-twenty years of his reign he apathetically resigned himself to the course of events. He died on April 1, 1548. By Bona he had five children—one son, Sigismund Augustus, who succeeded him, and four daughters, Isabella, who married John Zapolya, prince of Transylvania, Sophia, who married the duke of Brunswick, Catherine, who as the wife of John III. of Sweden became the mother of the Polish Vasas, and Ann, who subsequently wedded King Stephen Báthory.

See August Sokolowski, *History of Poland* (Pol.) vol. ii. (Vienna, 1904); Zygmunt Celichowski, *Materials for the history of the reign of Sigismund the Old* (Pol.) (Posen, 1900); Adolf Pawinski, *The youthful years of Sigismund the Old* (Pol.) (Warsaw, 1893); Adam Darowski, *Bona Sforza* (1904).

SIGISMUND II. (1520–1572), king of Poland, was the only son of Sigismund I. (*q.v.*), whom he succeeded in 1548, and Bona Sforza. At his first diet (Oct. 31, 1548), he came into conflict with the *szlachta*, now becoming powerful, who, secretly supported by the Austrian court and the queen-mother, threatened to renounce their allegiance unless he repudiated his second wife, the beautiful Lithuanian Calvinist, Barbara Radziwill, daughter of the famous Black Radziwill. But his firm refusal produced a reaction, and at the second diet (1550) the *szlachta* was less turbulent. On the death of Barbara, under suspicious circumstances, five days after her coronation (Dec. 7, 1550) Sigismund made a purely political marriage with the Austrian archduchess Catherine, sister of his first wife Elizabeth, who had died young. Catherine proving childless, Sigismund, being the last male of the Jagiellos in the direct line, was anxious to have an heir, and the diet had undertaken to legitimize and acknowledge any fruit of his liaisons with Barbara Gizanka and Anne Zajanczkowska; but the Habsburgs, who coveted the throne, successfully opposed the wish of the Protestant party, that he should divorce Catherine and remarry. Actually he survived the queen's death (Feb. 28, 1572) barely six months and died childless. Sigismund's reign was a period of internal turmoil and external expansion. He saw the invasion of Poland by the Reformation, the democratic upheaval which placed all political power in the hands of the *szlachta;* the collapse of the ancient order of the Knights of the Sword in the north (which led to the acquisition of Livonia by the republic); and the consolidation of the Turkish power in the south. Sigismund's most striking and personal achievement was the union of Lublin, which made of Poland and Lithuania one body politic; and put an end to the jealousies and discords of centuries. (*See* Poland: *History*.) He died at Knyszyne on July 6, 1572.

SIGISMUND III. (1566–1632), king of Poland and Sweden, son of John III, king of Sweden, and Catherine Jagiellonika, sister of Sigismund II., king of Poland, thus uniting in his person the royal lines of Vasa and Jagiello. Educated as a Catholic by his mother, he was on the death of Stephen Báthory elected king of Poland (Aug. 19, 1587) through the efforts of the Polish chancellor, Jan Zamoyski, and of his own aunt, Anne, queen-dowager of Poland. Sigismund promised to maintain a fleet in the

Baltic, to fortify the eastern frontier against the Tatars, and not to visit Sweden without the consent of the Polish diet. The articles of Kalmar regulated the future relations between Poland and Sweden, when Sigismund should succeed his father as king of Sweden. The two kingdoms were to be perpetually allied, but each of them was to retain its own laws. Sweden was also to enjoy her religion subject to such changes as a general council might make. During Sigismund's absence from Sweden that realm was to be ruled by seven Swedes, six to be elected by the king and one by Duke Charles, his Protestant uncle. Sweden, moreover, was not to be administered from Poland. The Poles first wished the cession of Estonia to Poland, but eventually the territorial settlement was postponed; and Sigismund was duly crowned at Cracow on Dec. 27, 1587.

From the first Sigismund was out of sympathy with the majority of his subjects. As a man of education and refinement, he was unintelligible to the *szlachta*, who regarded all artists and poets as either mechanics or adventurers. His reserve was called stiffness and his calm, haughtiness. Even Zamoyski who had placed him on the throne complained that the king was possessed by a dumb devil. He lacked, moreover, the tact and bonhomie of the Jagiellos.

The first 23 years of the reign are the record of a constant struggle between Zamoyski and the king. In 1592 Sigismund married the Austrian archduchess Anne, and a reconciliation was patched up between the king and the chancellor to enable the former to secure possession of his Swedish throne vacant by the death of his father John III. He arrived at Stockholm on Sept. 30, 1593 and was crowned at Upsala on Feb. 19, 1594, after he had consented to the maintenance of the "pure evangelical religion" in Sweden. On July 14, 1594 he departed for Poland leaving Duke Charles and the senate to rule Sweden during his absence. Four years later (July 1598) Sigismund was forced to fight for his native crown by the usurpation of his uncle, aided by the Protestant party in Sweden. He landed unopposed at Kalmar. After fruitless negotiations, Sigismund advanced with his army, but was defeated by the duke at Stängebro on Sept. 25. He never saw Sweden again, but refused to abandon his claims; and this unfortunate obstinacy was to involve Poland in a whole series of unprofitable wars with Sweden.

In 1602 Sigismund wedded Constantia, the sister of his deceased first wife, an event which strengthened the hands of the Austrian party at court and still further depressed the chancellor. At the diet of 1605 Sigismund endeavoured to substitute a decision by a plurality of votes for unanimity in the diet. The opposition of Zamoyski nullified the effect of this salutary reform. His death, however, in the same year left his more ardent followers without a check. From 1606 to 1610 Poland was in an anarchical condition. On foreign affairs these disorders had a disastrous effect. Poland was unable to take the opportunity of breaking the power of the tsars, which the collapse of Muscovy had shaken. At the outbreak of the Thirty Years' War Sigismund prudently leagued with the emperor against the Turks and the Protestants. Sigismund died very suddenly in his 66th year, leaving two sons, Wladislaus and John Casimir, who succeeded him in rotation.

SIGMARINGEN, a town of Germany, chief town of Hohenzollern, on the right bank of the Danube, 55 m. S. of Tübingen, on the railway to Ulm. Pop. (1925) 5,282. The castle of the Hohenzollerns crowns a high rock above the river.

The division of Sigmaringen or Hohenzollern is a part of Prussia and has an area of 440 sq.m. and a population (1925) of 71,773. It was formerly divided into the principalities of Hohenzollern-Sigmaringen and Hohenzollern-Hechingen. *See* HOHENZOLLERN.

SIGMOID: *see* ALIMENTARY SYSTEM.

SIGNAL (a word common in slightly different forms to nearly all European languages, derived from Lat. *signum*, a mark, sign), a means of transmitting information, according to some prearranged system or code, in cases where a direct verbal or written statement is unnecessary, undesirable, or impracticable. The methods employed vary with the circumstances and the purposes in view, and the medium into which the transmitted idea is translated may consist of visible objects, sounds, motions, or indeed anything that is capable of affecting the senses, so long as an understanding has been previously effected with the recipient as to the meaning involved. Any two persons may thus arrange a system for the transmission of intelligence between them, and secret codes of this kind, depending on the inflections of the voice, the accent on syllables or words, the arrangement of sentences, etc., have been so elaborated as to serve for the production of phenomena such as are sometimes attributed to telepathy or thought transference. With the many private developments of such codes we are not here concerned, nor is it necessary to attempt an explanation of the systems of drum-taps, smoke-fires, etc., by which certain primitive peoples are supposed to be able to convey news over long distances with astonishing rapidity; the following article is confined to giving an account of the organized methods of signalling employed at sea, in military operations and on railways, these being matters of practical public importance.

SIGNALLING. "Puff—double-puff; double-puff—puff!" So ran the signals made by the Picts beyond the Roman wall, their smoke puffs seen by the sentries of the legions but the signallers invisible and their meaning unguessed. And so, for thousands of years before, had savage peoples signalled their tidings of peace and war. The antiquity of signalling is undoubted, its lineage long and illustrious. For long centuries its chief purpose was to convey news of great events over great distances, and its application to the control of troops in battle is a development of yesterday.

THE PLACE OF SIGNALLING IN WAR

Its older forms, which are prehistoric, must be numbered among those savage arts that civilization kills but cannot emulate, of which the mysterious passage of news through the African bush is an example, to this day. Compared with them the famous beacon fires, calling England to arms as the Armada sailed up channel, were crude enough. The semaphore stations, each with its tall mast and signalling arms, which linked London with the south coast while Napoleon's Grand Army waited at Boulogne, were an advance, for they could spell out any message—they have given its name to more than one Telegraph hill in the south of England. In the early 19th century also, Sir Home Popham introduced the system of flag hoists in the British navy. But it is only with the help of applied science that civilized man has lately learnt to communicate with his fellows at a distance, by means of the "electric telegraph" of the mid-nineteenth century, to be followed two generations later by wireless telegraphy.

In spite of our evidence of man's need from early times to communicate afar, on the field of battle for countless years we see little sign of any attempt at control by signal. "Horns are heard blowing in the mist, and a confused uproar of savage tumult and outrage." Kings and captains, themselves in the thick of the press, were content to command by voice and example. It is not that the need was never felt; we learn in the Song of Roland how Charles the Great, as he marched north out of Spain, heard his lieutenant's horn blown for help in the mountains behind him; how he heard the signal twice and misread it, grasped its meaning the third time and turned back too late to save his rearguard. For one such incident made immortal in verse there must have been many lost in obscurity. None the less, through ages of warfare, the means of control in battle were more or less adequate to the needs. Firearms came and the long bow disappeared; modern nations appeared in arms, first the French and then the Germans, and tens of thousands co-operated on the battlefield in an iron discipline. Yet troops still fought in close order; generals continued to command from the saddle; the word of command, trumpet and bugle call and the galloping staff officer gave to commanders all the control they needed. The duke of Wellington could say at Waterloo, "The whole line will advance," and could watch the squares swing into line as his order took effect.

Then came the industrial revolution which was to affect war no less than every other branch of human activity, and in half a

century all was changed. In 1861 the beginning of the American Civil War saw the old order but little altered; the technique of war remained comparatively simple and dealt in the traditional elements of horse, foot and smooth-bore artillery. In 1918 the end of the World War saw armies so vast and so complex in armament that the most elaborate signal systems scarcely sufficed for their control. The process continues apace. In the second decade after the war we find a commander still disposing of infantry, artillery and cavalry, it is true; but half the infantry is armed with machine guns or automatic rifles; the gunner rarely sees his enemy; cavalry carry machine guns and must co-operate with mechanized fire units to retain their power of movement. The three older arms are altered beyond recognition, and in addition a commander has tanks, armoured cars and aircraft. These elements, widely deployed under the enemy's fire, he must weld into a single living organism, driven by one brain and working to one end. The problem of signalling is to enable a commander to achieve this ideal, and all his powers of fire and movement avail him only in so far as the problem is solved. Moreover, he must see before he can strike. All commanders grope in the fog of war, and the extent to which that fog may thin from time to time or allow a precious clear glimpse depends very much upon the state of signal communication. In addition, the infinite material needs of a modern army make as great demands upon intercommunication as does the actual conduct of battle.

ORIGIN AND GROWTH OF SIGNALLING

Birth of Signalling.—Before coming to any account of signalling in modern armies, we must go back a little to the invention of the electric telegraph. The first application of this invention to war was made by the British army in the Crimea in 1854, where a telegraph line was laid from Varna to the monastery of St. Georgia, from which lines were laid to Lord Raglan's headquarters and thence to established stations in the trenches. It was a curious intrusion of science and organization into a military system which was famous for neither and which was based upon the Brown Bess and the pack transport of the Peninsular War. In the Indian Mutiny three years later the scattered British forces were kept in telegraphic touch with one another and with the Government in Calcutta, and although this was an application of a civil telegraph service to military needs rather than an example of military signalling, yet it was remarkable as the first example of how the new system could be used to co-ordinate the movements of armies, and above all to transmit vital intelligence. That the newly established telegraph service was controlled by the Government and not by the forces of mutiny was one of the deciding factors in that struggle.

The American Civil War of 1861–65 saw a great development in the use of telegraphy with the armies in the field; and in the short and decisive Prussian campaign against Austria in 1866 a field telegraph equipment played an important part in keeping the directing brain of von Moltke in touch with the headquarters of the various armies. A few months afterwards the first British field telegraph unit was formed, entitled the Field Electric Telegraph Train, Royal Engineers. This unit is worth looking at a little closely, for it contained in itself the germ from which sprang the signal organization of the British armies which fought in the World War. It comprised two wire wagons and two office wagons; the two wire wagons each carried four miles of insulated cable on eight half-mile drums, and it is clear from this that here was a unit designed for the tactical control of troops in battle, as opposed to the long distance strategic uses of the telegraph which have been mentioned hitherto. Jointed poles were carried for raising the cable clear over roadways, but otherwise it was laid on the ground. Each office wagon formed a travelling telegraph office, and it is to be noted that in addition to the Morse recording instruments with which it was fitted, it carried visual signalling apparatus in wicker panniers suitable for pack animals, so that wire and visual communication could supplement one another.

So we come to visual signalling. In 1861 it had occurred to two British officers, Capt. Bolton of the 12th Regiment and Capt. Colomb, R.N., that the dots and dashes of the Morse alphabet could be transmitted by visual signals no less than by electric impulses over a wire. Working together they developed what they called "the flashing system," which made use of shutters or flags by day and lamps by night to form the dots and dashes, and which stands to this day with little change save in detail. The authorities took favourable notice of the new invention in a letter dated from the War Office on March 30, 1863. By 1865 it had been adopted for the British navy and army, and a code for signalling between H.M. ships and troops ashore had been drawn up. The following extract from *The Times* of Aug. 20, 1864, is interesting: "The Lords of the Admiralty . . . proceeded on board the 'Pigmy,' where they passed nearly an hour inspecting the signal apparatus fitted on board for carrying out the experimental signalling by day and by night, between positions in mid-Channel and Portsmouth Dockyard, under the direction of Captain Frank Bolton of the 12th Regiment, and Commander Colomb of Her Majesty's Navy. Their Lordships expressed their gratification at the manner in which this effective system of joint naval and military telegraphy had been developed by the exertions of these two officers. . . ."

Whether the idea travelled across the Atlantic or whether, as is likely enough, the same thought had spontaneous birth in two hemispheres, is not clear; but it is certain that the Federal army under Gen. Grant employed visual signalling in the American Civil War of 1861–65. In the British army the innovation had not long to wait for its trial on active service, and in the Abyssinian campaign of 1867–68 the 10th Company of Sappers in Sir Robert Napier's force contained an officer and a number of "telegraphers" especially instructed in the new art. Its success was immediate and remarkable, and it is perhaps difficult for later generations to realize the impression which it must have made upon an army accustomed only to the traditional means of message carrying by galloper and aide-de-camp. Some of the messages transmitted give interesting glimpses into the campaigning conditions of the country and period, but here there is room to quote one only: "From Captain Pottinger to Major Murray, R.A. Bring your battery up to Magdala. Better come on elephants. One hundred yards extremely Steep."

Later Developments up to the World War.—From the foregoing it may be seen that signalling started simultaneously in the old and new world during the '60s of last century. In the years which followed it grew in diverse ways according to the soil in which it was planted, and one of its most remarkable developments was the use of the heliograph for long distance communication on the northwest frontier of India. It was perhaps inevitable that those armies with traditions of fighting over wide spaces in undeveloped lands should pay more attention to signalling than did the forces of Continental Europe. Whatever the reasons there seems little doubt that Britain with her colonial empire, and the United States with their empty and uncivilised West attached especial importance to this branch of war. In fact it was not until 1902 that the first German signalling regulations appeared. The British army profited by the experience of its Indian frontier and colonial wars, and the South African campaign at the end of the century found it equipped with highly specialized Royal Engineer telegraph units, capable equally of erecting overhead telegraph wires, or of laying field cables across country at a speed limited only by that of the six-horse teams which drew the cable wagons.

The South African War was followed in the British army by a flowering and expanding period in both organization and training, such as it had not before experienced in times of peace. Signalling shared to the full in this development. Wireless telegraph units were added to the army, principally for communication with cavalry formations. Message carrying became recognized as the ally and not the rival of telegraphy in the field, and despatch riders on horse and motor cycle were included in the signal organization; their rôle was to carry the longer and less pressing messages and so to leave the telegraph free to deal immediately with short and urgent reports and orders. The intercommunication problem was thus seen as a whole, and this inclusion of despatch riding in the signal organization is one of the points which most distinguished the British from the Continental systems. The "telegraph" units of the South African War, which dealt only in line telegraphy,

gave place to "signal" units employing in co-operation line telegraphy, visual telegraphy and despatch riding. And as the British army was during this period definitely organized into divisions and brigades, so each formation had its own signal unit allotted to it for peace and war.

During these years the *signal office* organization came to be recognized, whereby at each important headquarters in the field the signal unit establishes a signal office, controlling all the available means of communications. Here the line telegraph operators work and the despatch riders wait their call, while the visual and wireless stations are as close outside as they can be placed. All outgoing messages from the headquarters are taken over at the signal office and there handed to the appropriate operator or despatch rider, and from there all incoming messages are distributed.

The British signal units were found from the Royal Engineers. It remained for the United States to go a step further and to form a separate signal corps; a notable organization which did not take long to make its mark in the world of science. In considering the policies which led the one country to retain signalling as a branch of military engineering and the other to form a specialist corps, it must be remembered that all telegraphic communication in Great Britain is a Government monopoly vested in the postmaster-general, so that the army's attention is confined to the purely military problem of communication in the field. The United States had no such federal organization, and their signal corps could and did provide important Government communications. Included among these was the wireless connection between the United States and their detached territories in Alaska. This pre-war period was marked by the wide use of heliograph and lamp signalling which the Germans made in their 1905 campaign in South-west Africa; and—of far greater import—by the intensive field telephone system in the siege operations of the Russo-Japanese War in 1904–05.

THE WORLD WAR

Trench Warfare and Fire Power.—The Powers entered upon the World War in 1914 equipped in varying degrees with line, visual and wireless telegraphy. In organization, military status and efficiency the signalling services of the armies varied greatly. At one end of the scale was Great Britain, whose signal units were worthy of that "perfect miniature" of which they formed part—the original Expeditionary Force. It seems that the small British army felt instinctively a greater need for efficient intercommunication in war to develop its full striking power, as compared with the vast forces of the Continent, which trained yearly by armies and army corps together and had long experience in the administration and manoeuvre of masses. At the other end of the scale stood Russia, putting her trust in numbers and neglecting the means to co-ordinate their movements. It was a neglect for which she paid dearly, and the annihilation of the Russian columns in East Prussia at the hands of Marshal von Hindenburg was due largely to the total lack of communication between them. At the same time the German drive through Belgium and Northern France, with which the war opened and which so nearly succeeded, owed its miscarriage in part to the failure of the wireless communication which was to have connected their general headquarters with the armies of the right wing. For a few short weeks the tide of battle in the west ebbed and flowed before it settled down to the long-drawn, bloody and apparently fruitless hammer and tongs of trench warfare. The outstanding feature of the latter phase was the overwhelming effect of fire. This, it is true, had been foreshadowed by the Russo-Japanese War and by progressive developments in magazine rifles, machine guns and both field and heavy artillery, but its terrific power was none the less a surprise to both sides.

Buried Cables and Emergency Methods.—Under the growing intensity of bombardment it soon became impossible to protect cables laid on the surface, and both sides were forced to put their lines underground; these were at first only a foot or two below the surface, but the steadily increasing weight of metal drove them deeper and deeper, until by 1918 six feet was the common depth and new systems were being installed eight feet underground. Thus on each side as the war went on there grew an immense gridwork of deep-buried cables, with main arteries every few thousand yards along the front running from the rear up to the forward trenches, joined across by lateral routes. Each buried route might contain 10, 20, 50 or more conductors and the systems included hundreds of underground test points and distributing centres. In the back areas, comparatively immune from shelling, the buried cables gave place to overhead systems stretching back over the lines of communication and conforming to the normal practice of civil telegraph engineering. So we have the phenomenon of rival armies, each seeking desperately to break through its opponent's line and fight in the open, growing more and more dependent upon a telephone system which must inevitably be left behind if that object should be gained.

The cables, even the most deeply buried, might be and frequently were cut at critical moments. At once the alternative visual and wireless methods held in reserve, inadequate though they were, became of vital importance. Visual signalling could no longer, under such a fire, be carried out by the traditional soldierly figure standing square on his feet with a flag. It generally took the form instead of an electric signalling lamp working through a deep embrasure, or of a small inconspicuous shutter showing just above the parapet; and any form of visual signalling working from the rear forwards was more than likely to be seen by the enemy and to draw his fire. Wireless signalling at that time laboured under the drawback that an exposed aerial was necessary, no less liable to be shot away than the cables were to be cut. The need for something less vulnerable led to the revival of an old principle, that of earth induction, whereby an alternating current in a length of wire connected to earth at each end induces corresponding impulses in a similar wire up to a distance of a few thousand yards. The wires could be buried and the instruments protected in dugouts so that the whole became comparatively shell-proof. As, however, each transmitter affected every receiver within its range they could be installed only at wide intervals along a front. Finally, each side evolved a code of firework signals, such as coloured lights, to be fired by the forward infantry if they should be attacked, each signal conveying its own message to the supporting artillery.

Other means were sought, less costly in life and less vulnerable to fire. These expedients all took the form of message carrying, and their agents were pigeons, messenger dogs and rockets. Of the three, pigeons were by far the most reliable; they might be delayed by darkness, chased by hawks, lost in the smoke and uproar or killed in crossing a barrage, but they made their lofts on the whole with remarkable regularity and sometimes showed a pathetic courage. More than one reached its loft wounded and died as it alighted, and one such in the French army was officially decorated for valour. Messenger dogs were less successful; their intelligence made them temperamental. Success demanded special treatment and a rigid discipline, which must be enforced not only by their kennelmen but by all with whom the dogs came in contact. Under these circumstances it was natural that the Germans, with their instinct for regulation, should achieve better results than their enemies. Nothing could prevent the British soldier from making a pet of any dog in his vicinity, and a dog which had been made much of in a forward position would not face the shell-swept open to regain his kennel. None the less in proper hands they could prove their worth. Rockets could carry a message some 2,000 yards across a region where neither runner nor signaller could live and where no wire could remain uncut; but to be successful they were required to drop a message with some certainty within reasonable reach of their destination, and this was a stage of reliability to which they never attained.

Air Co-operation.—While signalling was adapting itself to meet such changes in its old tasks, it found itself faced with a new duty, that of communicating with aircraft. A commander might have his eyes in the air above the enemy lines, but without the nerve connecting eye to brain he was little the better for it. At the outset aircraft of both sides were employed solely on reconnaissance and the pilot made his report after landing. It was not

long, however, before there was added to this the duty of observing for artillery, and this was made possible only by the adaptation of wireless telegraphy for signalling the fall of shell to the guns. At the same time the need arose for bodies of infantry, isolated after an attack and cut off by fire from their friends, to report their position and their predicament. This need was met to a limited extent in the different armies by codes of ground signals, displayed by the isolated troops to their own aircraft. The signals consisted generally of canvas strips laid out on the ground in set forms or groups of letters, each with its special meaning.

Tapping an Enemy's Communications.—The conditions of warfare on the Western front gave rise to a further new activity of signalling. A commander at all times has sought to read his enemy's mind; to divine "what is happening on the other side of the hill." In the war each commander found himself faced by the impenetrable barrier of the enemy's front line, behind which stretched the cables carrying intelligence of inestimable value to him, could he but hear it. So the rival intelligence bureaus asked their signallers if there were no means of tapping the enemy's cables. The experts worked for a time in closely guarded secrecy, and soon on either side unaccountable miscarriages began to occur. An attack would be planned in scrupulous detail; troops and staff would play their parts faultlessly, but at the critical moment an enemy bombardment, perfectly timed and directed, would turn the packed assembly trenches into a bloody chaos. Like incidents were repeated, for which the only possible explanation was that the enemy was possessed in detail of the plans for the operation.

But it is difficult in war to keep any development hidden for long. Somebody blundered on one side or the other; perhaps a prisoner boasted or an instrument was captured, and the secret was out. The experts of either side had taken the new invention of the triode valve, as it had been developed up to that point by wireless engineers, and had evolved from it an instrument so sensitive that it could read the traffic over an enemy's cables some thousands of yards away. The mysterious forewarnings vouchsafed were merely the enemy's operation orders intercepted word for word. The extent to which such eavesdropping was possible depended on various technical factors, and it was much reduced by the use of metallic circuits instead of earth return cables, but henceforth either side could use its forward cable system only in the knowledge that enemy listeners were straining their ears to overhear. Wireless telegraphy suffered of course at all times under the same limitation, to a much greater degree.

The Last Phase; Open Warfare.—On the Western front from the end of 1914 till the spring of 1918 the struggle grew in intensity but did not change its nature. The combatants fought where they stood; the line sagged and swayed as here or there a short advance was made at bitter cost; but it did not break and the chief concern of signalling was with fire power, to enable commanders to direct their ever-growing masses of emplaced artillery. Then came the German break-through by a supreme effort in March 1918—a feat of arms which was to spend itself within sight of victory and to be checked, held and at last turned back by the Western armies in their final advance to victory. The armies fought once more over the open; signalling was again concerned with troops in movement, and the underground telephone systems, constructed at such cost through three years of war, had to be left behind. The very reliance which their possessors had learnt to place in them became itself a handicap; few of the original combatants survived; those few had grown accustomed to the war of the trenches, and to most of those who fought in 1918 war without a lavish telephone system was a strange conception. Moreover, the armies which emerged from their trenches in 1918 were not those which had gone to ground three years beforehand; with more artillery and machine guns, with aerial co-operation, with tanks and armoured cars and with the new tactical methods which all these demanded, they could never again be satisfied with the 1914 scale of signal communication. Commanders were faced with the problem of how to co-ordinate movement, to direct fire power and to administer their formations in open warfare, unaided by the trench telephone system to which all had grown accustomed.

MARINE SIGNALLING

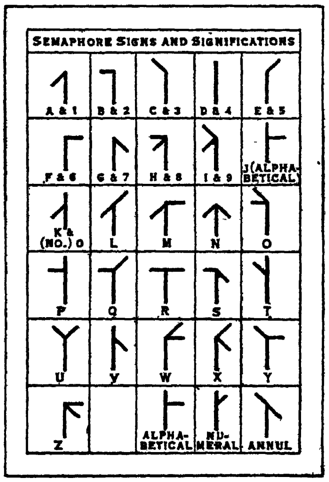
The main difference to be noted between signalling at sea and on land is that in the former case no physical connection, whether by wire or messenger, is possible. One is therefore restricted to visual, sound or wireless methods.

Visual methods, which are normally not effective beyond horizon distances (depending on visibility at the time), fall into two main categories, viz., day and night.

Flags.—By day, coloured flags and pendants have long been employed. These, originally, had purely arbitrary meanings, depending in many systems on the actual position where they were displayed in a ship. In the middle of the nineteenth century, however, standard colours were agreed upon internationally, and an "International" code of signals for use at sea was brought into force. The flags of the code include the twenty-six letters of the alphabet and a "code" pendant. By means of hoists not exceeding four flags, it is possible to make any signal from the International Code or spell out words not contained therein. The code has since been translated into the languages of the principal maritime Powers. A new edition of the International Code of Signals is now in active preparation.

Separate sets of flags and elaborate systems of grouping are in use by most navies to meet their special requirements.

Semaphore.—Visual communication by day can also be carried out by means of the semaphore, a device which exhibits one or more straight arms in certain positions. The early forms of the system were principally used by coast stations and were of the nature of fixed signals. These coast semaphores still exist, chiefly in France, but have been superseded, so far as signalling between ships is concerned, by a moving semaphore system employing only two arms, which are moved to consecutive positions (indicating letters of the alphabet) as necessary to spell out the message. It can be made by a mechanical semaphore or with the signalman's own arms. International agreement on this system has not been reached, but the alphabet shown here is in force in Great Britain and the United States. This is an extremely rapid form of communication at short distances, and transmission speeds of 25 words a minute or over can be attained by expert signalmen.



Flashing.—For longer distances by day, most large vessels are now equipped with powerful lamps or searchlights fitted with some form of louvre shutter, enabling the light to be flashed. Using Morse, messages can be spelt out verbatim or code groups signalled as desired. With brilliant lights of this nature communication can be effected by night between ships at more than horizon distance, provided that weather conditions are favourable.

At night, plain and coloured lanterns in various combinations constituted the earliest form of signalling, being superseded eventually by the introduction of flashing in conjunction with the Morse Code. Both by day and at night, the speed of transmission by flashing is comparatively slow on account of the physical limitations of the human eye, and a rate of 12 words a minute is seldom exceeded in practice.

Fireworks, *e.g.*, bonfire beacons, Roman candles, rockets, Very's lights, etc., have all been pressed into the service of signalling, but only the three last named still survive and their use is mainly confined to short messages of a standard nature, such as signals of distress, requests for a pilot, etc.

Sound Signals.—During fog or conditions of low visibility generally, sound signals are possible, and were until comparatively recent years in fairly common use. Formerly, more particularly in men-of-war, blank charges were fired from guns at various intervals to convey the meaning desired, but here again the Morse Code

was triumphant over the older method, first by means of the hand-worked foghorn and later by sirens driven by steam or compressed air. Sound signalling under these conditions, however, is extremely cumbrous and much slower even than flashing, and nowadays is chiefly used to indicate a ship's presence to others who may be in her vicinity.

Many modern navies have now adopted a system of underwater signalling in which sound impulses are communicated to the water by means of an electrically-driven oscillator and received by a microphone in the hull of other ships, who read off the signal in ordinary head telephones. Telegraphic speeds up to 20 words can be reached thus, though the range of transmission does not usually exceed 12 miles except under very good conditions.

Up to the end of the last century, the limitations of range inherent in the foregoing systems of signalling rendered long-distance communication with ships impossible. Once at sea and over the horizon, it was only possible to direct their movements or issue orders by cable messages sent to their known ports of call or the coast signal stations with which they would speak on their voyage. Conversely, a ship out of sight of land was equally impotent to report her position or notify distress or other casualty.

Wireless Signalling.—Wireless telegraphy (*see* WIRELESS TELEGRAPHY), with which the great majority of seagoing vessels are now legally bound to be equipped, has achieved one of the most spectacular changes of our age. It may fairly be said that no ship is now beyond the range of wireless, even though her own installation may be too weak to ensure her communication with the shore at all times.

It is hardly within the scope of this article to do more than indicate a few of the ways in which wireless telegraphy (including also its younger cousin, wireless telephony) serves the mariner. So far as navigation is concerned, powerful shore stations send out daily time signals correct to a fraction of a second, direction finding stations (if the ship herself has not a direction finding receiver on board) furnish her with her bearing from them, while a distress message in any of the seven seas will bring perhaps half a dozen vessels rushing to her aid. By means of wireless, passengers in ocean-going liners get their daily newspaper and bankers are enabled to pursue their financial operations on the high seas. Shipowners can divert their vessels in search of profitable cargoes, and admiralties control their fleets with a precision undreamed of in the old naval wars.

Historical Development.—The necessity of some plan of rapidly conveying orders or intelligence to a distance was early recognized. Polybius describes two methods, one proposed by Aeneas Tacticus more than three centuries before Christ, and one perfected by himself, which, as any word could be spelled by it, anticipated the underlying principle of later systems. The signal codes of the ancients are believed to have been elaborate. Generally some kind of flag was used. Shields were also displayed in a preconcerted manner, as at the battle of Marathon, and some have imagined that the reflected rays of the sun were flashed from them as with the modern heliograph. In the middle ages flags, banners and lanterns were used to distinguish particular squadrons, and as marks of rank, as they are at present, also to call officers to the admiral, and to report sighting the enemy and getting into danger. The invention of cannon made an important addition to the means of signalling. In the instructions issued by Don Martin de Padilla in 1597 the use of guns, lights and fires is mentioned. The introduction of the square rig permitted a further addition, that of letting fall a sail a certain number of times. Before the middle of the 17th century only a few stated orders and reports could be made known by signalling. Flags were used by day, and lights, occasionally with guns, at night. The signification then, and for a long time after, depended upon the position in which the light or flag was displayed. Orders, indeed, were as often as possible communicated by hailing or even by means of boats. As the size of ships increased the inconvenience of both plans became intolerable. Some attribute the first attempt at a regular code to Admiral Sir William Penn (1621–1670), but the credit of it is usually given to James II. when duke of York. Notwithstanding the attention paid to the subject by Paul Hoste and others, signals continued strangely imperfect till late in the 18th century. Towards 1780 Admiral Kempenfelt devised a plan of flag-signalling which was the parent of that now in use. Instead of indicating differences of meaning by varying the position of a solitary flag, he combined distinct flags in pairs. About the beginning of the 19th century Sir Home Popham improved a method of conveying messages by flags proposed by R. Hall Gower (1767–1833), and greatly increased a ship's power of communicating with others. The number of night and fog signals that could be shown was still very restricted. In 1867 an innovation of prodigious importance was made by the adoption in the British navy of Vice-Admiral (then Captain) Philip Colomb's flashing system, on which he had been at work since 1858.

SIGNATURE (through Fr. from Lat. *signatura*, *signare*, to sign, *signum*, mark, token, sign), a distinguishing sign or mark, especially the name, or something representing the name, of a person used by him as affixed to a document or other writing to show that it has been written by him or made in accordance with his wishes or directions. In the early sense of something which "signifies," *i.e.* marks a condition, quality or meaning, the word was formerly also used widely, but now chiefly in technical applications. In old medical theory, plants and minerals were supposed to be marked by some natural sign or symbol which indicated the particular medicinal use to which they could be put; thus yellow flowers were to be used for jaundice, the "scorpion-grass," the old name of the forget-me-not, was efficacious for the bite of the scorpion; many superstitions were based on the human shape of the roots of the mandrake or mandragora; the bloodstone was taken to be a cure for hemorrhage; this theory was known as the "doctrine of signatures." (*See* T. J. Pettigrew, *Superstitions connected with Medicine or Surgery*, 1844.) In printing or bookbinding the "signature" is a letter or numeral placed at the bottom of the first page of a section of a book, as an assistance to the bookbinder in folding and arranging the sections consecutively; hence it is used in connection with a sheet ready folded. In music it is the term applied to the signs affixed at the beginning of the stave showing the key or tonality and the time or rhythm.

SIGN-BOARD, strictly a board placed or hung before any building to indicate its character. The French *enseigne* indicates its essential connection with what is known in English as a flag (*q.v.*), and in France banners not infrequently took the place of sign-boards in the middle ages. Sign-boards, however, are best known in the shape of painted or carved advertisements for shops, inns, etc.; they are in fact one of various emblematic methods used from time immemorial for publicly calling attention to the place to which they refer. The ancient Egyptians and Greeks are known to have used signs, and many Roman examples are preserved, among them the widely-recognized bush to indicate a tavern, from which is derived the proverb "Good wine needs no bush." In some cases, such as the bush, or the three balls of pawnbrokers, certain signs became identified with certain trades, but apart from these the emblems employed by traders—evolving often into trade-marks—may in great part be grouped according to their various origins. Thus, at an early period the cross or other sign of a religious character was used to attract Christians, whereas the sign of the sun or the moon would serve the same purpose for pagans. Later, the adaptation of the coats-of-arms or badges of noble families became common; these would be described by the people without consideration of the language of heraldry, and thus such signs as the Red Lion, the Green Dragon, etc., have become familiar. Another class of sign was that which exhibited merely persons employed in the various trades, or objects typical of them, but in large towns where many practised the same trade, and especially, as was often the case, where these congregated mainly in the same street, such signs did not provide sufficient distinction. Thus a variety of devices came into existence—sometimes the trader used a rebus on his own name (*e.g.*, two cocks for the name of Cox); sometimes he adopted any figure of an animal or other object, or portrait of a well known person, which he considered likely to attract attention. As early as the 14th century there was a law in England compelling publicans to exhibit signs, for in 1393 the prosecution of

a publican for not doing so is recorded. In France edicts were directed to the same end in 1567 and 1577. Since the object of sign-boards was to attract the public, they were often of an elaborate character. Not only were the signs themselves large and sometimes of great artistic merit (especially in the 16th and 17th centuries, when they reached their greatest vogue) but the posts or metal supports protruding from the houses over the street, from which the signs were swung, were often elaborately worked, and many beautiful examples of wrought-iron supports survive both in England and on the Continent. The signs were a prominent feature of the streets of London at this period. But here and in other large towns they became a danger and a nuisance in the narrow ways. Already in 1669 a royal order had been directed in France against the excessive size of sign-boards and their projection too far over the streets. In Paris in 1761 and in London about 1762–73 laws were introduced which gradually compelled sign-boards to be removed or fixed flat against the wall. For the most part they only survived in connection with inns, for which some of the greatest artists of the time painted sign-boards.

See J. Larwood and J. C. Hotten, *History of Sign-boards* (London, 1866).

SIGNIA (mod. *Segni*), an ancient town of Latium (*adiectum*), Italy, on a projecting lower summit of the Volscian mountains, above the Via Latina, some 35 m. S.E. of Rome. The modern railway station, 33 m. S.E. of Rome, lies 5 m. S.E. of Signia, 669 ft. above sea-level. The modern town (2,192 ft.) occupies the lower part of the ancient site. Pop. (1921) 7,044. Its foundation as a Roman colony is ascribed to Tarquinius Superbus, and new colonists were sent there in 495 B.C.

The city wall, constructed of polygonal blocks of the mountain limestone and 1¼ m. in circumference, is still well preserved and has several gates; the largest, Porta Saracinesca, is roofed by the gradual inclination of the sides until they are close enough to allow of the placing of a lintel. The other gates are mostly narrow posterns covered with flat monolithic lintels, and the careful jointing of the blocks of which some of them are composed may be noted. Their date need not be so early as is generally believed and they are quite certainly not pre-Roman. Above the modern town, on the highest point, is the church of S. Pietro, occupying the central cella of the ancient Capitolium of Signia (which had three cellae). The walls consist of rectangular blocks of tufa, and the whole rests upon a platform of polygonal masses of limestone. An open circular cistern in front of the church lined with rectangular blocks of tufa may also be noted.

SIGNIFICS is the systematic study of signs and symbols of every kind, including not only words and their meanings, but also volitional intentions and axiological significance (or values). The aim of significs is to classify, correlate and interpret meanings of every kind. (*See* MEANING; SEMANTICS.)

See E. Martinak, *Psychologische Untersuchungen zur Bedeutungslehre* (1901).

SIGN LANGUAGE. Speech as a mode of human intercourse is normally used between persons who are in visible contact. Therefore the gestures, facial expressions, bodily movements of the two parties are integral, even at times essential, elements in the intercourse. Thus "when the postural tensions and the spoken word contradict each other it is plain which should be given credence" (W. A. White, *Foundations of Psychiatry*, 1921, p. 79). There is therefore in all speech when the two parties are in visible contact an element of natural gesture. From this concept we arrive at the position that to speak with the hands is to think with the hands.

Organized sign language is found in many parts of the world. In Assam "the signs used depend on the genius and personality of the speaker, but the natural aptitude for their use is such that from one Naga to another their meaning is rarely obscure. Indeed the writer has known a dumb man make a long and detailed complaint of an assault in which nothing was missing except proper names, and even these were eventually identified by means of the dumb man's description of his assailant's dress and personal appearance" (J. H. Hutton, *Angami Nagas*, 1921, p. 291). Natural gestures form the basis of an extended system of sign language, as is evident in Australia.

SIGN-MANUAL, ROYAL, the autograph signature of the sovereign, by which he expresses his pleasure either by order, commission or warrant. A sign-manual warrant may be either an executive act, *e.g.*, an appointment to an office, or an authority for affixing the Great Seal. The Anglo-Saxon kings did not sign their charters, their names being invariably written by an official Scribe. There is no royal signature before those of Richard II.

The employment of marks or signs manual went out of general use after the 12th century, in the course of which the affixing or appending of seals became the common method of executing deeds.

In the course of the 14th century the name-signature was added to the seal; and by the 15th century it had become established. The *signum manuale* disappeared but the term survived, and was transferred to the signature. In England, an act, 23 of 1830, provided for the use of a Stamp in place of the sign-manual under certain restrictions. The sign-manual must be counter-signed by a principal secretary of State or other responsible minister.

SIGNORELLI, LUCA (*c.* 1450–1523), Italian painter, of the Umbro Tuscan School, was born in Cortona—his full name being Luca d'Egidio di Ventura. Luca was apprenticed to Piero della Francesca at Arezzo where he lived in the house of his uncle Lazzaro Vasari. His first recorded work was the decoration of an organ at Landi near Cortona. In 1472 Luca worked at Arezzo and in 1474 at Città di Castello on paintings no longer extant. In 1475 he probably was in Florence; from 1479–1481 his presence in Cortona is proved by documents. During this time probably Pope Sixtus IV. commissioned Signorelli to paint the frescoes, now mostly very dim, in the shrine of Loreto. In 1482–83 he worked in the Sistine Chapel in Rome. In the fresco "The Last Will of Moses" he was helped by assistants; he painted also two apostles and three portrait figures into Perugino's fresco "The handing over of the keys to St. Peter." Luca may have stayed in Rome till 1484. After a visit to Gubbio and Perugia he returned to his native Cortona, which remained from this time his ordinary home. From 1497 he began some professional excursions. At Monteoliveto near Siena he painted frescoes of the life of St. Benedict (1497) and in S. Agostino, Siena, an altarpiece (1498). The next year he went to Orvieto, and here he produced the works which, beyond all others, stamp his greatness in art. These are the frescoes in the chapel of S. Brizio, in the cathedral, which already contained some pictures on the vaulting by Fra Angelico. The works of Signorelli represent the "Last Days of the Mundane Dispensation," with the "Pomp and the Fall of Antichrist," and the "Eternal Destiny of Man," and occupy three vast lunettes, each of them a single picture. In one of them, Antichrist, after his portents and impious glories, falls headlong from the sky, crashing down into an innumerable crowd of men and women. "Paradise," the "Elect and the Condemned," "Hell," the "Resurrection of the Dead," and the "Destruction of the Reprobate" follow in other compartments. To Angelico's ceiling Signorelli added a section showing figures blowing trumpets, etc.; and in another ceiling he depicted the Madonna, Doctors of the Church, Patriarchs and Martyrs. There is also a great deal of subsidiary work connected with Dante, and with the poets and legends of antiquity. The daring and terrible invention of the great compositions, with their powerful treatment of the nude and of the most arduous foreshortenings, and the general mastery over complex grouping and distribution, marked a development of art which had never previously been attained. In 1502 he returned to Cortona, and painted a dead Christ, with the Marys and other figures now in the cathedral.

In 1506 he was in Siena to submit his design of "The Judgment of Solomon" for the pavement of the cathedral. In 1507 he executed a great altarpiece for S. Medardo at Arcevia in Umbria—the "Madonna and Child," with the "Massacre of the Innocents" and other episodes. In 1508 Pope Julius II. determined to re-adorn the *camere* of the Vatican, and he summoned to Rome Signorelli, in company with Perugino, Pinturicchio and Bazzi

(Sodoma). They began operations, but were shortly all superseded to make way for Raphael, and their work was taken down. Luca afterwards lived for the most part in Cortona. The works of his later years though signed with his name were mostly the work of his pupils. In 1521 Luca painted the panel of "The Holy Trinity, Virgin, Infant and Saints" in the Uffizi, Florence; and in 1523 he had completed the "Virgin, Infant, Angels and Saints" at Foiano. His last work, left unfinished, was a fresco of the "Baptism of Christ" in the chapel of Cardinal Passerini's palace near Cortona. Signorelli entered the magistracy of Cortona as early as 1488. In the year 1523 he died there.

Signorelli surpassed all his contemporaries in showing the structure and mechanism of the nude in immediate action. His drawings in the Louvre demonstrate this. He aimed at powerful truth rather than nobility of form; colour was comparatively neglected, and his chiaroscuro exhibits sharp oppositions of lights and shadows. He had a vast influence over the painters of his own and of succeeding times, but had no pupils or assistants of high mark. Among his chief works not mentioned above may be named: "The Flagellation" in the Brera, Milan (an early work); "School of Pan"; two groups of Saints (from S. Agostino, Siena); and the portrait of a lawyer—all four in the Berlin Museum. In the Uffizi Florence are: "The Madonna with Child and Shepherds" and "The Holy Family." The National Gallery, London, has a "Circumcision" and other works.

SIGOURNEY, LYDIA HUNTLEY (1791–1865), American author, was born in Norwich (Conn.), Sept. 1, 1791. She was a precocious child, and became one of the most popular authors of her day. After conducting schools in Norwich and Hartford, she was married, in 1819, to Charles Sigourney, a Hartford merchant. She contributed more than 2,000 articles to nearly 300 periodicals, and wrote more than 50 books. She died in Hartford, June 10, 1865. She was called "The American Hemans."

SIGSBEE, CHARLES DWIGHT (1845–1923), an American naval officer, was born on Jan. 16, 1845, in Albany, N.Y. He graduated from the U.S. Naval Academy in 1863 and served in the latter part of the Civil War at the battle of Mobile, and in the attacks on Ft. Fisher. He received his commission as master in 1866, lieutenant 1867, lieutenant-commander 1868 and commander 1882. He made a deep sea exploration of the Gulf of Mexico and invented several deep sea appliances and machines. He was chief hydrographer of the Naval department, 1893–97, and superintendent of naval construction at the Academy at Annapolis. He was commissioned captain in 1897 and put in command of the battleship *Maine*. The *Maine* was ordered to Havana harbour in Jan. 1898, and was there mysteriously destroyed by a terrific explosion on the 15th of February. Sigsbee commanded the cruiser *St. Paul* which performed excellent service throughout the Spanish-American War. He was promoted to rear admiral in 1903. He died in New York July 19, 1923. He wrote *Deep Sea Sounding and Dredging* (1880); *Personal Narrative of the Battleship Maine* (1899).

SIGÜENZA, a city of central Spain and episcopal see in the province of Guadalajara on the Madrid-Saragossa railway, 87 m. north-east of Madrid, on the left bank of the Henares. Pop. (1920) 4,013. Sigüenza, the ancient Segontia, climbs in picturesque irregular streets of many-coloured crumbling sandstone to the Alcazar on the top of the hill. The chapel of Santa Catalina has flags captured from the English in 1589.

SIGURD (*Sigurðr*) or **SIEGFRIED** (M.H.G. *Sîfrit*), the hero of the *Nibelungenlied,* and of a series of poems of an earlier date in the *Elder Edda,* as well as of the prose *Völsunga Saga,* which is based, in great part, upon the latter. According to both the Scandinavian and German versions of his legend, he was the son of a certain Sigmundr (Siegmund), a king in the Netherlands, or the "land of the Franks." The exploits of this Sigmundr and his elder sons Sinfjötli and Helgi form the subject of the earlier parts of *Völsunga Saga,* and Siegmund and (his nephew) Fitela (*i.e.* Sinfjötli) are also mentioned in the Anglo-Saxon poem *Beowulf.* According to the Scandinavian story Sigmundr was slain in battle before the birth of Sigurd, but the German story makes him survive his son. Sigurd acquired great fame and riches by slaying the dragon Fáfnir, but the chief interest of the story centres in his connection with the court of the Burgundian king Gunnar (Gunther). He married Guðrun (Kriemhild), the sister of that king, and won for him by a stratagem the hand of the Valkyrie Brynhild, with whom he had himself previously exchanged vows of love. A quarrel arose between Brynhild and Guðrun, in the course of which the former learnt of the deception which had been practised upon her and this led eventually to the murder of Sigurd. According to the Scandinavian version he was slain by his brother-in-law, Guttorm, according to the German version by the knight Hagen. Gunnar's brothers were subsequently slain while visiting Atli (Etzel), or Attila, king of the Huns, who married Guðrun after Sigurd's death. According to the German story they were killed at the instigation of Kriemhild in revenge for Siegfried. The Scandinavian version attributes the deed to Atli's lust for gold.

The story of Sigurd is of German rather than Scandinavian origin, and has given rise to more discussion than any other subject connected with the Teutonic heroic age. Like Achilles he is represented as the perfect embodiment of the ideals of the race, and, as in the case of the Greek hero, it is customary to regard his personality and exploits as mythical. There is no question, however, that the Burgundian king who is said to have been his brother-in-law was an historical person who was slain by the Huns, at the time when the Burgundian kingdom was overthrown by the latter. Sigurd himself is not mentioned by any contemporary writer; but, apart from the dragon incident, there is nothing in the story which affords sufficient justification for regarding his personality as mythical. Opinions, however, vary widely as to the precise proportions of history and fiction which the story contains. The story of Siegfried in Richard Wagner's famous opera-cycle *Der Ring der Nibelungen* is mainly taken from the northern version; but many features, especially the characterization of Hagen, are borrowed from the German story, as is also the episode of Siegfried's murder in the forest.

Lichtenberger, *Le poème et la légende des Nibelungen* (1891); B. Symons, "Heldensage" in H. Paul's *Grundriss der germ. Philologie,* vol. iii. (Strasbourg, 1900); and R. C. Boer, *Untersuchungen über den Ursprung und die Entwicklung der Nibelungensage* (Halle, 1906). Also Th. Abeling, *Das Nibelungenlied und seine Literatur* (1907).

SIGURÐSSON, JÓN (1811–1879), Icelandic statesman and man of letters, was born in the west of Iceland in 1811. He received an excellent education. In 1830 he was secretary to the bishop of Iceland, the learned Steingrimr Jónsson. In 1833 he went to Copenhagen to study Icelandic history and literature. His important works include: *Lögsögumannatal og Lögmanna à Islandi* ("Speakers of the Law and Law-men in Iceland"); the edition of *Landnáma* and other sagas in *Islendinga Sögur,* i.–ii. (Copenhagen, 1843–1847); the large collection of Icelandic laws edited by him and Oddgeir Stephensen; and last, not least, the *Diplomatarium Islandicum,* which after his death was continued by others.

But although he was one of the greatest scholars Iceland has produced, he was still greater as a politician. The Danish rule had, during the centuries following the Reformation, gradually brought Iceland to the verge of economic ruin. Jón Sigurðsson began a hard struggle against the Danish government to obtain a reform. In 1854 the trade of Iceland was declared free to all nations. In 1840 the Althing was re-established as an advisory, not as a legislative body. But when Denmark got a free constitution in 1848, which had no legal validity in Iceland, the island felt justified in demanding full home rule. To this the Danish government was vehemently opposed; it convoked an Icelandic National Assembly in 1851, and brought before that body a bill granting Iceland small local liberties, but practically incorporating Iceland in Denmark. This bill was indignantly rejected, and, instigated by Jón Sigurðsson, another was demanded of far more liberal tendencies. The Danish governor-general then dis-

solved the assembly, but Jón Sigurðsson and all the members with him protested to the king against these unlawful proceedings. The struggle continued with great bitterness on both sides, but gradually the Danish government was forced to grant many important reforms. (*See* ICELAND, *History.*)

The grant of the constitution in 1874 was, in fact, the victory of Jón Sigurðsson, whose high personal qualities had rallied all the nation round him. He made Reykjavik not only the political, but the spiritual capital of Iceland by removing all the chief institutions of learning to that city; he was the soul of many literary and political societies, and the chief editor of the *Ny Félagsrit,* which has done more than any other Icelandic periodical to promote the cause of civilization and progress in Iceland. Jón Sigurðsson lived the greater part of his life in Copenhagen, and died there in 1879; but his body, together with that of his wife, Ingibjörg Einarsdóttir, whom he had married in 1845, and who survived him only a few days, was taken to Reykjavik and given a public funeral. On his monument was placed the inscription: "The beloved son of Iceland, her honour, sword and shield."

(S. BL.; X.)

SIGYNNAE, an obscure people of antiquity (Gr. Σίγυνναι Σίγυννοι). They are variously located by ancient authors. According to Herodotus (v. 9), they dwelt beyond the Danube, and their frontiers extended almost as far as the Veneti on the Adriatic.

The similarity between Sigynnae and Zigeuner is obvious, and it has been supposed that they were the forefathers of the modern gipsies. According to J. L. Myres, the Sigynnae of Herodotus were "a people widely spread in the Danubic basin in the 5th century B.C.," probably identical with the Sequani (*q.v.*).

SIKHS, a sect of dissenters from Brahmanical Hinduism. It originated in the Punjab, where most of the *Sikha,* "disciples," are still to be found. Although the fetters of Brahmanism have long been firmly riveted on India, attempts to loosen them date back to Buddhism (*q.v.*) and were renewed by many religious and social reformers from whom Sikhism borrowed ideas and even devotional hymns. Such were Jaidev, composer of the *Gīta Govind* (translated by Edwin Arnold), who *c.* A.D. 1100 taught that Yoga (*q.v.*) was worthless in comparison with God's worship in thought, word and deed; Rāmānand, at the close of the 14th century, freed his followers from caste restrictions; a little later Kabīr (b. 1398) denounced idolatry and ritualism. Nearly a century later, in 1469, was born Nānak, the first founder of Sikhism, contemporary with Luther. His name means "he who was born at the home of his mother's parents," and it lay at Talwandi, near Lahore. Of a Kshatri family (the Kshatriya had once been formidable spiritual rivals of the Brahmans) a curious, but hardly contemporary, Sikh account of his descent makes him a reincarnation of the king of the Videhas, Janaka the great patron of the Kshatrya *Upanishads* (*q.v.*). The tradition may contain a grain of truth. As a young man he must have seen something of Sultān Sikandar Lodi's (1489–1517) measures against Hinduism.

Early Period.—Nānak's faith was sternly monotheistic. He taught the worthlessness of religious vestments, of ostentatious prayer and penance, pilgrimages and fanes. He declared that all men had a right to search for knowledge of God, irrespective of caste. He was a quietist, and though we have no authentic biography of him, we may conjecture that his life and doctrines did not expose him to persecution, and we hear nothing of any efforts to suppress his teaching. He was employed by a Muslim, and was married, leaving on his death in 1533 two sons, Sri Chand and Lakhmi Das, both Hindu names. Nānak, however, had designated as his successor in his spiritual mission the Gurū-ship, another Kshatri, Lehna, who took the name of Angad. (Angada was a lesser legendary hero of the Epic age.) To Gurū Angad is due the inception of the *Granth* ("book") *Sāhib* ("holy"), in which he embodied what he had learnt from Gurū Nānak, adding devotional reflections of his own. To mark the sacred character of the work, he is said to have invented Gurmukhi, the "Gurū's tongue," the peculiar script of the Sikhs, by modifications of the Shārada alphabet. Dying in 1552, Angad in turn excluded his sons and designated the Kshatri Amār Dās as his successor. The reforms of this Gurū were important, including the separation of the Udāsi order, founded by Nānak's own son Sri Chand, from the laity, denunciation of Sati, and the stressing of Nānak's attitude to caste by making all his Sikhs eat together. He also divided the country covered by his missioners into 22 sees. Dying in 1574, Amār Dās bestowed the Gurū-ship on his servant and son-in-law Jetha, under the name of Rām Dās.

To him is due the foundation of the golden temple built at Amritsar in 1579 on a site granted him by the emperor Akbar, whose policy aimed at welding all the creeds of India into one. Rām Dās taught no new doctrines but is still much revered. He died in 1581.

So far, the Gurūs had aimed at continuing the Gurū-ship by designation, not at setting up a hereditary spiritual dynasty. But after Rām Dās the eastern tendency, so marked in Islam, to regard saintship as vested in a saint's physical descendants asserted itself. Still Rām Dās selected his third son, Arjan Dev (*Arjuna* was a legendary, semi-divine hero of the Epics; *Deva* was a title borne by an old Rajput dynasty of Jammū), to follow him as Gurū, though the Sikhs regarded Pirthi Chand as so entitled by right of primogeniture and the latter would probably have made good his claim to inherit the Gurū-ship but for his exactions. Arjan was induced to insist on his right, though he had meekly surrendered his father's turban, the symbol of temporal rulership, to Pirthi Chand. He established a rude fiscal system appointing collectors of offerings. Gurū Arjan enlarged the *Granth,* half of which is due to him, and is said to have been arraigned before Akbar for setting up a new divinity, but the eclectic emperor naturally acquitted him. Arjan, however, made a fatal mistake in aiding Prince Khusrū, a rebel against his father Jahāngīr, with a modest sum of money. Possibly this act was dictated by a belief that Khusrū would continue Akbar's tolerant policy, but it may have been a forced loan.

Jahāngīr punished it with a fine of two lakhs of rupees, which Arjan was unable or unwilling to pay and so he was, it is said, tortured to death in 1606. To his son Har Govind, who succeeded him without contest he left a behest to maintain his throne by arms. Gurū Har Govind was installed with turban and necklace only but added an aigrette to the one and for the other substituted a sword-belt. The Gurū-ship was now launched on a new adventure—the foundation of a militant sacred dynasty. The Gurū founded the first Sikh stronghold, enlisted horse and foot, and encouraged his disciples to eat flesh to improve their physique.

After 12 years' imprisonment in the fortress of Gwalior Har Govind obtained his freedom, probably by paying the fine imposed on Arjan. This imprisonment must have preceded his military activities. By them he was enabled to resist Shāh Jahān (1627–66) and claimed three victories over the imperial troops. But he died in 1645 in a remote valley of the lower Himalayas at Kiratpur on the upper Sutlej, which indicates that he had found it safer than Amritsar. Shāh Jahān, who had destroyed many Hindu temples, appears to have taken no special measures against the Sikhs. Har Govind's grandson, Har Rai, who succeeded him, was undoubtedly a supporter of the unfortunate Dārā Shikoh, who had the *Upanishads* partly done into Persian and professed mystical Sūfī heresies. On that prince's execution in 1659 Har Rei was summoned to Delhi but sent his elder son Rām Rai instead, and on his death two years later Rām Rai was excluded from succeeding him as being a hostage or prisoner, his younger brother Har Kishen assuming the Gurū-ship, though still a child. His death in 1664 left the direct line extinct and the inheritance reverted to Teg Bahādur, Har Govind's second son, but he was executed by Aurangzeb in 1675 for having refused to accept Islam. His prophecy that Europeans were coming from beyond the seas to destroy the Moghul empire became the Sikh battle-cry at the siege of Delhi in 1857.

Middle Period.—The tenth and last Gurū was his son, Govind Rai, who took the affix *Singh,* "lion," in lieu of Rai and remodelled the Sikh organization which he renamed Khālsa, "pure." He made the Sikh initiation (*pahul*) a rite of admittance into a militant order. In that rite, with a two-edged dagger (*khanda*) sugar is stirred up in water, which the novice drinks and with which he is lustrated five times. He then utters the Sikh war-cry

vowing adherence to the Sikhs' tenets. Thenceforth he must wear the five k's, the *kes,* unshorn hair, the *kachh,* drawers reaching only to the knee, the *kara,* iron bangle, the *kirpan,* sword (or *khanda,* small dagger) and *khanga* or hair comb. Of these the first four have soldierly uses, the long hair rolled round steel rings serving as a helmet and so on. But they have also a spiritual meaning, *e.g.,* the *kachh* symbolizing self restraint, the bangle obedience, and the comb purity of mind. The use of flesh and liquor is permitted as to a warrior, but tobacco as a narcotic is prohibited. Govind Singh also instituted the *karā parshād,* a kind of communion at which flour mixed with butter and sugar is eaten by all castes together.

Govind Singh waged an active defensive against the Moghul power but his levies were dispersed and his two sons put to death by the governor of Sirhind. On Aurangzeb's death, however, he aided Bahādur Shad, but in 1708 he was assassinated at Nander in the Deccan. Sonless and mistrustful of Banda Bairāgi, who claimed to be the eleventh Gurū, Govind Singh declared the line of Gurūs extinct and the Gurū-ship vested in the *Granth Sahib* as God's representative on earth. Sikhism was thenceforth to be a militant theocracy, but it soon formed a mass of military bands under Sirdārs ("chiefs"). The earlier military organization of the Sikhs is obscure. Banda seems to have formed an almost regular army, but after gaining notable successes against the Moghuls, sacking Sirhind and compelling the allegiance of the Hindu hill-rājās who had generally refused to submit to the Gurūs, he had to cede Amritsar to the true Singhs, the Tat Khālsa, elect of the elect, and was finally executed in 1716. His death left the Sikhs leaderless, but they were strong enough to extort grants of land from Farrukhsiar and formed two armies, a veteran and a younger. The latter comprised five companies, including the militant order of *shahīds,* which carried its forays in Rājpūtāna. On the Punjab, thus distracted, fell Nādir Shāh's invasion of 1738–39. Its last great Moghul governor, Adīna Beg, recovered part of the province, but on his death in 1758 the Sikhs mastered the central and north-east Punjab. They now appear as better organized. Besides the Shahīds, three new orders were formed with eight *misls* or confederacies. Under Jassa Singh (elected head of the Ahluwālia *misl; bādshā* ["monarch"], to his own followers, and by caste a potter on the earlier Sikh coins) there materialized as it were a cabinet of *gurūs,* the *gurū matta* "sacred council," convened by the Akālis or the *granthis* about 1762 at Amritsar. South of the Sutlej the reversion to kingship was accelerated when Ālā Singh of Patiāla leased the province of Sirhind from Ahmad Shāh with the title of king (rājā) of kings, and the lessor's retreat from the Punjab left the Sikhs its masters from the Jamna to the Indus in 1767. But in 1808 Ranjīt Singh suppressed the confederacy which bore the standard of the Khālsa; and the dissensions of the other *misls* enabled him, then merely the chief of the territorial confederacy, to absorb the rest, conquer Kashmīr and Peshāwar, subdue the hill states and set up a hereditary monarchy, though he still minted Sikh coins and upheld Sikhism as the state religion. But he appointed Mohammedan *qāzīs* and *muftis* ("judges and law-officers"), and protected Muslim states like Maler Kotla and many institutions of that creed, which had befriended Sikhs from time to time.

Later Period.—The history of Sikhism in the 19th century belongs rather to the history of the Punjab (*see* INDIA, *History*), but the Sikh sub-sects and orders were mostly maintained. The differences with Hinduism tended, however, to be suppressed. Thus the Akālis lost ground, though the Kūkas remained staunch to their extremist tenets, with diminished numbers. Sects like the Sanwal-Shāhis, followers of a disciple of Gurū Nānak, are all but confined to the south-west Punjab, while the Sewapanthis are still more restricted to the Sindh Sāgar Doāb. The Hindālīs forfeited their once influential position by throwing in their lot with Ahmad Shāh Abdāli and are now known as Narinjani or worshippers of the Bright One (God). The Nirankāris, a modern sect, revived Nānak's teaching though they respect later Gurūs also. The older orders became Sikh castes, like the Rāmgarhias, whose founder was a carpenter and which is now the Sikh carpenter caste; as the Sikh Kallāls or Nebs (potters) style themselves Ahluwālia. Every confederacy worked out its own destiny, tending to form hereditary chiefships and divide the villages it had occupied among its members as if they were private lands. To a certain extent the mutiny revived Sikhism by stimulating anti-Muslim feeling, and this recrudescence probably saved it from becoming a mere collection of more or less Hinduized sects in which the Nānak-panthis would have absorbed the Khālsa or sect of Gurū Govind Singh. But the revival was militarist rather than religious. The sectarian institutions decayed. Little was added to religious literature. In a sense the *Granth* became the Gurū, receiving divine honours, for example at Conjeeveram, in the south, where it became the object of a fire sacrifice. The book of common prayer was the *Panjgranthi,* including five poems from the *Granth,* three of which have to be recited daily by the Khālsa Sikhs; yet Sikh ascetics used to make pilgrimages to Hindu temples. The Khālsa college at Amritsar was, however, founded, and there too the chief Khālsa Dīwān had his headquarters. It made grants to various schools, including some 30 for girls. Local societies, Singh Sabha, were established throughout the Punjab and even beyond it.

There was very little innovation in the religious sphere, but Sikhism was still alive awaiting a stimulus to arouse its latent power. This came to it from education, the general awakening of India, and the mal-administration of the sectarian shrines and temples.

Laity.—When Sikhism revived, all its divisions were equally resuscitated. A notable example of this was furnished by the Kūkas ("shouters"), who professed to be ethically strict followers of Govind Singh but observed such secrecy that they were debited with the degrading practices so often ascribed to such sects. The Kūka insignia, a high straight turban and a knotted necklace or rosary of wool, hint at an originally military asceticism and possibly at some connection with Banda Bairāgi, but their significance has never been disclosed. Supposed to be hostile to British rule, the Kūkas were certainly anti-Muslim, especially resenting the slaughter of kine, carefully planning the assassination of Mohammedan butchers and once organizing, in 1872, an armed rising which took the shape of a raid into the Muslim state of Maler Kotla. Owing to the drastic action of the district officer of Ludhiāna who executed over 100 mutineers by artillery the rising speedily collapsed, but severe as was the method of its suppression, it had undoubtedly excited the Sikh population and a less decisive one might in the end have resulted in more bloodshed. On the other hand the fanatical Akālis only revived as a body of harmless eccentrics practising their rites at Sikh gatherings, and not taken seriously by any other Sikh body. The Udāsi order became hardly distinguishable from a Hindu religious sect and was even regarded as Vaishnava.

The Nirmalas were not quite re-Hinduized but the general tendency of the Sikh laity was towards emergence into Brahmanism. Only the more ardent followers of Govind Singh preserved their distinctive tenets, dress, and protestant, anti-Brahmanical attitude. Thus ended the first phase of the Sikh revival. The second phase was greatly fostered if not initiated by the formation of the Imperial Service troops. The Sikh recruits in the Phulkian states, south of the Sutlej, had often neglected to take the *pahul.* They were encouraged to do so by their British inspecting officers, and the military spirit of Sikhism was enhanced. With its revival came an awakened interest in other things. The Sikhs, even the stricter elements, had acquiesced in the decay of their religious institutions. In 1863 the British Government had by statute divested itself of all administrative control over religious endowments, but had provided no machinery to assume its functions. The Sikh orders had no written constitutions. Such an order as the Udāsi was in theory celibate. It proceeded to permit its members to marry, to found families of great respectability and influence, who were accepted as owners of the religious shrines and wealthy refectories, and administered them as private properties—on the Brahmanical model. But Brahmanism allows no lay interference with Brahman property.

Orders.—The humbler village fanes were equally appropriated by their incumbents, who naturally favoured the fatal principle of

hereditary rights in them. The Kūka headship became a kind of dynasty. The Akālis alone retained celibacy, but even the Nirmalas failed to enforce it rigidly. But celibate or not, no order evolved any definite system of selecting its heads. The powers of the abbots, of the chapter and of the congregation were undefined. If, then, the glebe was alienated by a dissolute incumbent, or endowments mis-spent by incompetent abbots, the sole remedy for the laity was a suit in the courts, which begged the whole question of the layman's right to ask for relief by treating the priestly rights in the shrine as a matter of custom—of custom recently created by priestly malfeasance. Ignoring the fundamental doctrines of Sikhism in general and of its orders in particular, the courts proceeded to give legal recognition to the vested interests of the carnal heirs of spiritual offices in their benefices. This led to grave unrest among the Sikhs. Even the administration of the Khālsa college, founded under British auspices, had to be remodelled. The golden temple at Amritsar, being a purely religious foundation, was, however, beyond Government control. Internal dissensions made its problems difficult of solution. Its governing body had long been divided, one party permitting its walls to be adorned with Hindu mythological pictures, another condemning them as incompatible with Sikh monotheism. The Sikhs at a mass meeting accepted a provisional council, only in part nominated by Government, to draw up a scheme of management. But it failed to function. In 1920 the Mahātma Gandhi intervened, suggesting the appointment of the Shiromani Gurūdwāra Parbandhak committee for the management of shrines in general. This body proceeded at once to the high-handed seizure of places of worship, including the golden temple itself. It also reorganized the Akālis, recruiting them with lawless *jathas,* gangs of turbulent elements not all furnished by the Sikhs. It called on the Udāsi *mahant* or "abbot" of Gurū Nānak's birthplace, Nānkāna, to reform his institution. In defence of his property the Gurū enlisted Muslim mercenaries and so exacerbated Sikh feeling. A body of 130 Sikhs seized the sanctuary but were massacred to a man. Equally lawless seizures of shrines ensued. At Gurū kā Bāgh, the "Gurū's Garden," the Akālis captured the Gurūdwāra or fane of the Gurū, but the *mahant* held its house and lands. The committee took steps to seize some of the latter as appurtenant to the shrine, but the law was here successfully vindicated and no fewer than 5,000 Akālis arrested. In reprisal, the Akāli order threw off a new and more militant offshoot in the Babbar ("lion") Akālis dedicated to the murder of village officials and others loyal to Government but in their isolation beyond its effectual protection. The tract between the Sutlej and Biās rivers was terrorized by Akāli and other lawless gangs, marked men being openly assassinated and property indiscriminately plundered. Soldiery alone secured a semblance of order. Yet in 1923, when communal riots between Hindus and Muslims broke out at Amritsar the Akālis aided authority to maintain order. In 1924, however, the shrines committee espoused the cause of the misguided Mahárája of Nābha, who abdicated after levying private war on the sister Sikh state of Patiāla, and at Jaitoke a meeting of the new ruler's opponents had to be dispersed. The Akālis came to the rising, but their peaceful purpose was merely the perpetual recitation of the *Granth* for the restoration of the ex-Rājā. Unfortunately they were reinforced by a huge mob which attacked the State forces. It was beaten off with a loss of 50 men, including 21 killed and only three or four Akālis fell. In 1925 the Sikh Gurūdwāra and Shrines bill became law. It set up legal machinery for the control of Sikh endowments, and if it is alleged to be unjust to the Sikh orders, it must be pleaded that the failure of those orders, even of the Udāsis, to organize their own self-discipline and protect the rights of the Sikh congregations made it a necessity. The disruptions in the Udāsi order made it impossible to give legal embodiment to it or to anyone of its branches.

SIKH WARS, two Indian campaigns fought between the Sikhs and the British, which resulted in the conquest and annexation of the Punjab (*see* Punjab).

FIRST SIKH WAR (1845–46)

The first Sikh War, or Sutlej campaign, was brought about by the insubordination of the Sikh army, which after the death of Ranjit Singh became uncontrollable and on Dec. 11, 1845, crossed the Sutlej, and virtually declared war upon the British. The British authorities had foreseen the outbreak, and had massed sufficient troops at Ferozepore, Ludhiana and Umballa to protect the frontier, but not to offer provocation. So complete were the preparations for advance that on the 12th, the day after the Sikhs crossed the Sutlej, Sir Hugh Gough, the commander-in-chief, marched 16m. with the Umballa force to Rajpura; on the 13th the governor-general, Sir Henry Hardinge, declared war, and by the 18th the whole army had marched 150m. to Moodkee, in order to protect Ferozepore from the Sikh attack. The Sikh army is referred to for brevity as "the Sikhs," but it was composed of Sikhs, Punjabi Muslims and Hindus, as are the present Sikh regiments of the Indian army. Gurkha, Hindostani and Afghan mercenaries were also found in the ranks.

Wearied with their long march, the British troops were enjoying a rest, when the news came in that the Sikhs were advancing to battle at four o'clock in the afternoon. The British had some 10,000 men, and the Sikhs are estimated by some authorities as low as 10,000 infantry with 2,000 cavalry and 22 guns. The battle opened with an artillery duel, in which the British guns, though inferior in weight, soon silenced the enemy, the 3rd Light Dragoons delivered a brilliant charge, and the infantry drove the enemy from position after position with great slaughter and the loss of seventeen guns. The victory was complete, but the fall of night prevented it from being followed up, and caused some of the native regiments to fire into each other in the confusion.

Ferozeshah.—After the battle of Moodkee Hardinge volunteered to serve as second in command under Gough, a step which caused some confusion in the ensuing battle. At 4 A.M. on Dec. 21 the British advanced from Moodkee to attack the Sikh entrenched camp under the command of Lal Singh at Ferozeshah, orders having been sent to Sir John Littler, in command at Ferozepore, to join the main British force. At 11 A.M. the British were in front of the Sikh position, but Littler though on his way had not yet arrived. Gough wished to attack while there was plenty of daylight; but Hardinge re-asserted his civil authority as governor-general, and forbade the attack until the junction with Littler was effected. The army then marched on to meet Littler and the battle did not begin until between 3.30 and 4 P.M. The engagement opened with an artillery duel, in which the British failed to gain the mastery over the Sikhs, owing to the light weight of the British ordnance. The infantry, therefore, advanced to the attack; but the Sikh muskets were as good as the British, and fighting behind entrenchments they were a most formidable foe. Littler's attack was repulsed, the 62nd Regiment losing heavily in officers and men, while the sepoys failed to support the European regiments. But the Moodkee force, undaunted, stormed and captured the entrenchment, though the different brigades and regiments lost position and became mixed up together in the darkness. The army then passed the night on the Sikh position, while the Sikhs prowled round keeping up an incessant fire. In the morning the British found that they had captured seventy-three pieces of cannon and were masters of the whole field; but at that moment a fresh Sikh army, under Tej Singh, came up to the assistance of the scattered forces of Lal Singh. The British were exhausted with their sleepless night, the native troops were shaken, and a determined attack by this fresh army might have won the day; but Tej Singh, after a half-hearted attack, which was repulsed, marched away, whether from cowardice, incapacity or treason, and left the British masters of the position.

Aliwal.—After the battle of Ferozeshah the Sikhs retired behind the Sutlej, but early in January they again raided across the river near Ludhiana, and Sir Harry Smith was detached to pro-

tect that city. On Jan. 21 he was approaching Ludhiana when he found the Sikhs under Runjoor Singh in an entrenched position flanking his line of march at Budhowal. He passed on without fighting a general action, but suffered considerable loss in men and baggage. After receiving reinforcements Sir Harry again advanced from Ludhiana and attacked the Sikhs at Aliwal on Jan. 28. An attack upon the Sikh left near the village of Aliwal gave him the key of the position, and a brilliant charge by the 16th Lancers, which broke the Sikh square, completed their demoralization. The Sikhs fled in confusion, losing sixty-seven guns, and by this battle were expelled from the south side of the Sutlej.

Sobraon.—Ever since Ferozeshah Gough had been waiting to receive reinforcements, and on Feb. 7, his siege train arrived, while on the following day Sir Harry Smith's force returned to camp. On Feb. 10 Gough attacked the Sikhs, who occupied a strong entrenched position in a bend of the Sutlej. After two hours cannonading, the infantry attack commenced at 9 A.M. The advance of the first brigade was not immediately successful but the second brigade following on carried the entrenchments. The cavalry then charged down the Sikh lines from right to left and completed the victory. The Sikhs, with the river behind them, suffered terrible carnage, and are computed to have lost 10,000 men and 67 guns. The British losses throughout the campaign were considerably heavier than was usual in Indian warfare; but this was partly due to the fact that the Sikhs were the best natural fighters in India, and partly to the lack of energy of the Hindostani sepoys. After the battle of Sobraon the British advanced to Lahore, where the treaty of Lahore was signed on March 11.

SECOND SIKH WAR—PUNJAB CAMPAIGN 1848–49

For two years after the battle of Sobraon the Punjab remained a British protectorate, with Sir Henry Lawrence as resident; but the Sikhs were unconvinced of their military inferiority, the Rani Jindan and her ministers were constantly intriguing to recover their power, and a further trial of strength was inevitable. The outbreak came at Multan, where on April 20, 1848, the troops of the Dewan Mulraj broke out and attacked two British officers, Mr. Vans Agnew and Lieutenant Anderson, eventually murdering them. On hearing of the incident, Lieut. Herbert Edwardes, who was Lawrence's assistant in the Derajat, advanced upon Multan with a force of levies drawn from the Pathan tribes of the frontier; but he was not strong enough to do more than keep the enemy in check until Multan was invested by a Bombay column under General Whish. In the meantime Edwardes wished for an immediate British advance upon Multan; but Lord Gough, as he had now become, decided on a cold season campaign, on the ground that, if the Sikh government at Lahore joined in the rising, the British would require all their available strength to suppress it. Multan was invested on Aug. 18 by Whish in conjunction with the Sikh general Shere Singh; but during the course of the siege Shere Singh deserted and joined the rebels, thus turning the rising into a national war. The siege of Multan was temporarily abandoned, but was resumed in November, when Gough's main advance had begun, and Mulraj surrendered on Jan. 22. In the meantime Gough had collected his army and stores, and on Nov. 9, crossed the Sutlej.

Chillianwalla.—On Nov. 22 there was a cavalry skirmish at Ramnagar, in which General Cureton and Colonel Havelock were killed. For a month after this Gough remained inactive, waiting to be reinforced by Whish from Multan; but at last he decided to advance without Whish, and fought the battle of Chillianwalla on Jan. 13, 1849. Gough had intended to encamp for the night; but the Sikh guns opening fire revealed the fact that their army had advanced out of its intrenchments, and Gough decided to seize the opportunity and attack at once. An hour's artillery duel showed that the Sikhs had the advantage both in position and guns, and the infantry advance commenced at three o'clock in the afternoon. The battle resulted in great loss to the European regiments, the 24th losing all its officers in a few minutes, while the total loss in killed and wounded amounted to 2,338; but when darkness fell the British were in possession of the whole of the Sikh line. Gough subsequently retired to the village of Chillianwalla, and the Sikhs returned and carried off their guns. After the battle Gough received an ovation from his troops, but his losses were thought excessive by the public in England and the directors of the East India Company, and Sir Charles Napier was appointed to supersede him. Before, however, the latter had time to reach India, the crowning victory of Gujrat had been fought and won.

Gujrat.—After the fall of Multan Whish marched to join Gough, and the junction of the two armies was effected on Feb. 18. In the meantime the Sikhs had withdrawn from their strong intrenchments at Russool, owing to want of provisions, and marched to Gujrat, which Gough considered a favourable position for attacking them. By a series of short marches he prepared the way for his "last and best battle." In this engagement, for the first time in either of the Sikh wars, the British had the superiority in artillery, in addition to a picked force of 24,000 men. The battle began on the morning of Feb. 21 with two and a half hours' artillery fire, which was overwhelmingly in favour of the British. At 11.30 A.M. Gough ordered a general advance covered by the artillery; and an hour and a half later the British were in possession of the town of Gujrat, of the Sikh camp and of the enemy's artillery and baggage, and the cavalry were in full pursuit on both flanks. In this battle the British only lost 96 killed and 700 wounded, while the Sikh loss was enormous, in addition to 67 guns. This decisive victory ended the war. On March 12, the Sikh leaders surrendered at discretion, and the Punjab was annexed to British India.

See Sir Charles Gough and A. D. Innes, *The Sikhs and the Sikh Wars* (1897); R. S. Rait, *Life and Campaigns of Viscount Gough* (1903).

SI KIANG, a river of south China, rising in the plateau of Yunnan, on land over 6,000 ft. above sea-level. The headwaters flow first of all southward and then turn northward, the southern boundary of Kwei Chow. In this section of the course it is generally known as Pa-ta-ho. The river next forms the boundary between the provinces of Kwei Chow and Kwang Si, for some distance being known in sections as the Hung Shui. It flows now through the much dissected and contorted ancient land mass of south-eastern China. Opposite Szengen the river has fallen slightly below 600 ft. above sea-level. Later it receives the Lung Kiang on the left bank. The river in this section is known as the Wu-ni-kiang, and later as the Si Kiang. Near Sünchow the Yu Kiang enters on the right. This tributary also rises in Yunnan, and has followed a course similar to that of the upper Si Kiang. The course of the main river to the neighbourhood of Sünchow has been a very rapid one, but from here to the sea, in spite of subsequent gorges and rapids, its course is more suitable to navigation. At Wuchow the Kwei Kiang enters from the left. After Chaoking the river splits up into a number of streams and forms a great delta. The Pe Kiang enters near the head of the delta. The northern section of the delta streams, on which Canton stands, is known as the Canton river or Chu Kiang. From Canton southwards a large inlet reaches to the sea. The Tung Kiang, a north bank tributary, also drains into the delta region. The entire length of the Si Kiang may be estimated at 1,250 miles. It is navigable in flood time for vessels drawing 16 ft. to Wuchow, and at ordinary times for vessels drawing 6 ft. or more to the same city. Light craft use the river as far as Hsing-i-fu.

The Si Kiang is the great commercial highway in south China, and in one way or other links Hongkong, Canton, Macao, Chaoking and Wuchow with the interior.

SIKKIM, a protected State of India, situated in the eastern Himalaya. Area 2,818 sq. miles. The country is a mass of mountains and consists of part of the main chain of the Himalayas and of ranges projecting southwards and gradually lessening in height. On the west the Singalila range divides Sikkim from Nepal, the chief pass into which is Chiabhanjan-la (10,320 ft.). On the east the Chola range forms the boundary with Tibet, the chief passes being the Natu-la and Jelep-la, both over 14,000 ft. Between these two ranges the country is split up into mountain ridges and a succession of deep valleys, which in the south are only 1,000 ft. above sea-level. The highest peaks are Kin-

chinjunga (28,146 ft.), Siniolchu, or D.2 (22,520 ft.), Kinchinjhau (22,509 ft.) and Chomiomo (22,385 ft.). The line of perpetual snow lies at about 17,000 feet. Between 12,000 and 15,000 ft. there are occasional plateaux, with some small lakes, *e.g.*, at Changur, to which cattle are driven for grazing in the summer. Forests cover the mountain slopes from 9,000 to 12,000 ft. and lower down give place to cultivation. From 6,500 to 4,500 ft. the slopes have been completely denuded and brought under cultivation, crops of maize, millets and pulses being raised. At lower levels the slopes are terraced and rice is grown wherever irrigation is possible. The chief river is the Tista, which is formed by the confluence of the Lachen and Lachung in the north of Sikkim. The valleys drained by these two affluents are broader and more open than those in the south into which the steep sides of the mountains descend abruptly, forming narrow gorges. The capital is at Gangtok. As is natural in a country with elevations varying from 1,000 to over 28,000 ft., every variety of climate and vegetation, sub-tropical, temperate and arctic, is encountered. The rainfall is heavy, as the mountains are exposed to the moisture-laden monsoon winds blowing up from the Bay of Bengal and averages 137 in. a year at Gangtok. The exuberance of the flora may be imagined when it is considered that the flowering plants comprise some 4,000 species of rhododendron. Butterflies abound and comprise about 600 species. Among mammals, the most interesting are the snow leopard, the cat-bear, the musk deer and two species of goat antelope.

The population numbers (1921) 81,721, of whom the majority are Nepalese by origin or actual birthplace. The other races are chiefly Bhotias of Tibetan extraction (11,580) and Lepchas (9,021). The Lepchas, whose own name for themselves is Rongpa, *i.e.*, the people of the valleys or ravines, are believed to be the earliest inhabitants of Sikkim and to be of Indo-Chinese origin. As their name implies, they are chiefly denizens of the warmer valleys. A peaceful, simple people, they have been replaced at higher levels by the more industrious and pushing Nepalese, who are a hardy race of cultivators. The Bhotias are mainly graziers, who make their homes at higher elevations. Buddhism, the State religion, is professed by one-third of the inhabitants, chiefly the Bhotias and Lepchas, for most of the Nepalese are Hindus. There are a number of Buddhist monasteries picturesquely placed on the summits and shoulders of the hills, of which the most important is at Pemionchi. The Buddhism prevalent is of the lamaistic type found in Tibet. The population is essentially agricultural, each family living in a homestead on its own land; and there are no close clusters of houses that can be dignified with the name of village except round a few market places and in the Lachen and Lachung valleys.

History.—The ruling family is Tibetan, and claims descent from one of the Gyalpos or princelings of eastern Tibet. Their ancestors found their way to Lhasa and, in 1641, overcame the Lepcha chiefs of Sikkim. One of them established his government and introduced Buddhist Lamaism as a State religion. Till the end of the 18th century Sikkim was practically a dependency of Tibet, where its ruler was designated Governor of Sikkim.

British relations with Sikkim began in 1816, when the Tarai or submontane portion of Sikkim (now included in Darjeeling), which had been occupied by the Nepalese, was restored to the raja by the treaty concluded at the end of the Nepalese War. In 1839 the site of Darjeeling was ceded to the British for use as a sanatorium. In 1849 the British resumed the whole of the Tarai and the outer hills, as punishment for repeated insults and injuries culminating in the imprisonment of Dr. Campbell, superintendent of Darjeeling, and Sir Joseph Hooker, when travelling in Sikkim. In 1861 the despatch of a British force was required to impose a treaty defining good relations. The maharaja, however, refused to carry out his obligations and persisted in living in Tibet; his administration was neglected, his subjects oppressed, and a force of Tibetan soldiers was allowed, and even encouraged, to erect a fort in Sikkim territory. The Government was forced in 1888, to send an expedition, which drove the Tibetans back over the Jelep pass. A convention was then concluded with China in 1890, whereby the British protectorate over Sikkim was acknowledged and the boundary of the State defined; to this was added a supplemental agreement relating to trade and domestic matters, which was signed in 1893. A British political officer was appointed to assist the maharaja in the administration with a Durbar or Council composed of the chief civil officers and lamas. The maharaja refused to co-operate and tried to flee to Tibet through Nepal, where he was stopped by the Nepalese and made over to the British. He then resided as a State prisoner near Kurseong in the Darjeeling district and died in 1914. The present maharaja, Sir Tashi Namgyal, K.C.I.E., who succeeded in 1914, was invested with full ruling powers in 1918.

SILAGE: *see* ENSILAGE.

SILAS (*fl.* A.D. 50), early Christian prophet and missionary, was the companion of St. Paul on the second journey, when he took the place formerly held by Barnabas. The tour included S. Galatia, Troas, Philippi (where he was imprisoned), Thessalonica and Beroea, where Silas was left with Timothy, though he afterwards rejoined Paul at Corinth. He is in all probability the Silvanus[1] who is associated with Paul in the letters to the Thessalonians, mentioned again in 2 Cor. i. 19, and the bearer and amanuensis of 1 Peter (*see* v. 12). It is possible, indeed, that he has an even closer connection with this letter, and some scholars (*e.g.*, R. Scott in *The Pauline Epistles*, 1909) are inclined to give him a prominent place among the writers of the New Testament. He was of Jewish birth and probably also a Roman citizen.

SILAY, a municipality (with administration centre and 9 *barrios* or districts) of the province of Occidental Negros, Island of Negroes, Philippine Islands, on the north-west coast, about 10 m. N. of Bacolod, the provincial capital. Pop. (1918) 23,328.

SILCHESTER, a parish in the north of Hampshire, England, about 10 m. S. of Reading, containing the site of the Romano-British town Calleva Atrebatum. The site was completely excavated between 1889 and 1909 and the whole plan of the ancient town within the walls recovered; unfortunately the excavators had to abandon their task before the suburbs, cemeteries and whatever else may lie outside the walls have been examined. The results are published in *Archaeologia*, the official organ of the London Society of Antiquaries. (*See* BRITAIN: *Roman.*) As the excavations proceeded, the areas excavated were covered in again, but the ruins of the town hall, which have been famous since the 12th century, still remain.

SILENT TRADE: *see* TRADE, PRIMITIVE.

SILENUS, in mythology, the son of Hermes (or Pan) and a nymph. The companion and nurse of Dionysus, he often appeared in art and in satyr-plays in the god's train. He now and then emerged into cult, and a story, variously located in Asia Minor or Macedonia, showed King Midas as catching one (there were presumably many Silenuses, SILENOI, old satyrs, *q.v.*) by making him drunk, and as being instructed by him on the woes of human life. In art he generally appears as a little pot-bellied old man, with a snub nose and a bald head, riding on an ass and supported by satyrs; or he is depicted lying asleep on his wine-skin, which he sometimes bestrides. A more dignified type is the Vatican statue of Silenus carrying the infant Dionysus, and the marble group from the villa Borghese in the Louvre.

See Preller-Robert, *Griechische Mythologie* (1894), pp. 729–35; Roscher's *Lexikon* (s.v.).

SILESIA, the name of a district in the East of Europe, the greater part of which is included in the German republic and is known as German Silesia. A smaller part, called Austrian Silesia, was included in the empire of Austria Hungary.

German Silesia, a province of Prussia, is bounded by Brandenburg, Grenzmarke, Poland, Czechoslovakia, and the republic and province of Saxony. Besides the bulk of the old duchy of Silesia, it includes the countship of Glatz, a fragment of the Neumark, and part of Upper Lusatia, taken from the kingdom of Saxony.

[1]For the abbreviation, *cf.* Lucas, Prisca (=Priscilla); Sopater (=Sosipater).

in 1815. The province, which has an area of 14,022 sq.m. and is the largest in Prussia, is divided into three governmental districts, those of Liegnitz and Breslau comprising lower Silesia, and of Oppeln taking in the greater part of mountainous Silesia. By the Treaty of Versailles it was decreed that 122 sq.m. of territory in Upper Silesia, with a population of 48,446, should be ceded to Czechoslovakia. In nearly all the other districts of Upper Silesia it was ordained that a plebiscite should be taken as to whether they should remain German or become Polish. The plebiscite was taken in 1921, and, though the total majority was for Germany, many districts had Polish majorities; this led to difficulties and the question was referred to a commission of the council of the League of Nations. According to the findings of this commission 1,241 sq.m., with a population of 892,457, were assigned to Poland. The new boundary cut across a homogeneous industrial area, and, in order to alleviate economic distress, certain stipulations were made whereby the internal commerce of the area could be carried on very much as before. In 1925 the population of Lower Silesia was 2,988,541, of Upper Silesia 1,-299,144, giving a density per sq.m. of 304 and 368 respectively. In Lower Silesia two-thirds of the population is Protestant, in Upper Silesia the great majority is Roman Catholic.

Physiographically the province falls into three parts. Along its south-western border we have the Sudetic range, its ridge presenting an almost unbroken line, everywhere over 1,500 ft. high, and rising to over 5,000 ft. in the Riesen Gebirge. This range is composed of Archaean and Primary rocks, the latter of which have, in places, coal-bearing strata. The south-eastern and eastern boundaries are drawn along the Tarnowitz Plateau and its north-westward extension; this plateau is formed of secondary rocks, but in the south there are carboniferous outcrops. Between these two sets of heights lies Silesia proper, a depression watered by the Oder and its tributaries, and covered with recent deposits, among which fairly large stretches of loess are notable. The average January temperature is about 30° F; July 70° F, but the figures vary greatly at different altitudes. On the lowlands the annual rainfall is just over 20 in., but it is much higher on the hills.

The mines and the good agricultural land attracted German settlers up the Oder in the middle ages, and the land became essentially German, but there are traces of the older Wendish population still to be found among the inhabitants. In the plain, especially on the loess, there is rich agricultural land, and the chief crops are wheat, oats, hops, sugar-beet and fruit. To the north of the Oder the land is poorer, heath and scrubby pine-woods, and here the potato, rye and flax are the agricultural staples. The same is true of the Lusatian region. In earlier times Silesia was famed for its sheep, and wool, flax and an abundance of water led to the establishment of a textile industry. Later cotton was introduced and water-power was replaced by steam produced by coal from the neighbouring mines. At Görlitz and Schweidnitz woollens are manufactured, at Hirschberg and Neustadt linen, at Glatz and Reichenbach cotton, and at Schmiedeberg carpets and plush. Several of these towns also manufacture glass and porcelain. At Waldenburg coal is mined, and there are ironworks; the manufacture of machinery is carried on in many Silesian towns.

The slopes of the Sudetes are covered with fine pine forests and here we have manufactures dependent on a good supply of wood; *e.g.*, paper, toys and matches. The plain, with its soft rocks, is supplied with building material from the quarries of the Sudetes. Above the tree line are the summer pastures of large herds of cattle. It is only the smaller share of the great industrial region of the south-east that has remained to Germany, but Silesia is still important for its coal mines, and its iron-, lead- and zinc-smelting works. Along the Sudetes at various places there are mineral springs.

The main line of communication is the railway that runs from Sagan via Liegnitz and Breslau to Oppeln, where it branches, sending one arm to Beuthen in the industrial south-east, and the other via Ratibor, the upper Oder and the March valleys towards Vienna. This main line throws off a number of branches north-eastward to Poland. Another line runs roughly parallel to it from Hoyerswerden to Ratibor passing through a number of industrial towns. It is linked with the main line at numerous points. The Sudetes are crossed by three important railways, from Görlitz, from Waldenburg and from Glatz. The Oder is navigable nearly throughout the province, *i.e.*, from Kosel, whence the Klodnitz canal enables barges to tap the industrial region around Gleiwitz and Hindenburg. The bigger cities in the plains have varied manufactures, and Breslau is the commercial as well as the political capital. For administrative purposes the province is divided into 14 city and 57 rural circles.

HISTORY

Early Period.—From the evidence of place-names, it appears as though the population of Silesia was at one time Celtic; but when its historical records begin with its incorporation into the new kingdom of Poland (*c.* A.D. 1000), we find it populated by Slavonic tribes, one of which, deriving its name from the mountain Zlenz, gave Silesia its name. On the death of Boleslaw III. of Poland (1138), his dominions were partitioned, and Silesia was constituted a separate principality, which in 1163 was divided into the *ducatus Zlesie* and the *ducatus Opoliensis,* these again disintegrating during the succeeding centuries into ever smaller units. By the end of the 14th century, Silesia consisted of 18 principalities: Breslau, Brieg, Glogau, Jauer, Liegnitz, Münsterberg, Oels, Schweidnitz and Steinau in Lower Silesia; Beuthen, Falkenberg, Kosel, Neisse, Oppeln, Ratibor, Strehlitz, Teschen and Troppau in the upper district. As members of the Piast house and *principes Poloniae,* the Silesian dukes remained outside the German empire; but as from the first they adopted the policy of inviting German settlers to fill their vacant land, and founding towns which enjoyed German law, their lands soon became virtually German. The result was much material prosperity; forest and swamp lands were reclaimed; the weaving and mining industries acquired great importance and Breslau (which was refounded *c.* 1250 as a German town) became a large market for the wares of the East and the West.

At the beginning of the 14th century the Silesian dukes exchanged their nominal allegiance to Poland for allegiance to Bohemia, becoming members of the Empire; and as some of the Piast dynasties died out, their lands were appropriated as crown land by the Kings of Bohemia. The earlier Bohemian overlords justified their intrusion by their vigorous administrative and other reforms; the cities in particular enjoyed greatly increased material prosperity and political importance. Later, however, the Bohemian connection involved Silesia in the Hussite wars. In 1420 Silesia supported Sigismund against the Bohemian rebels, whom it regarded as dangerous to the German nationality, but suffered in consequence a series of devastating invasions (1425–35) which permanently weakened the German element. Had the Hussite, George Podiebrad, who was accepted by most of the Silesian dynasties, but fiercely repudiated by the burghers of Breslau, retained the Bohemian throne which he mounted in 1457, the Slavonic element might have regained the upper hand; but he was replaced by Matthias Corvinus, whom Silesia readily recognised as overlord. Corvinus' reforms, although effective, were financially exacting, and under his successor Vladislav the Silesians exacted concessions which gave them virtual autonomy.

The estates of Silesia accepted the accession of Ferdinand I. of Habsburg without demur (Dec. 5, 1526), but under their new dynasty they soon lost almost all their old rights, and the land gradually passed to the Crown as the old dynasties became extinct. After an uneventful period, the land was almost ruined by the Thirty Years' War (1618–48) in which Silesia, which was almost wholly Protestant, had joined with the rebellious Bohemians. It was punished less severely than Bohemia, but for years was the battlefield of contending armies, and overrun by lawless mercenaries. Three quarters of the population lost their lives, and trade and industry were brought to a standstill. Owing to the permanent diversion of trade routes, and the disregard by the Habsburgs of their undertakings towards their Protestant subjects, recovery was slow, although the representatives of Charles XII. of Sweden secured for the Silesians some religious liberty,

and the emperor Charles VI. tried to stimulate trade with Austria.

In 1740 Frederick II. of Prussia laid claim to the former Duchies of Liegnitz, Brieg, Jägerndorf and Wohlau, on the strength of a testamentary disposition made in 1537 and later annulled. He occupied Lower Silesia, which Maria Theresa was forced to yield him in 1741, and in 1742 extorted from Austria the whole remainder of Silesia except the districts of Troppau, Teschen and Jägerndorf. Maria Theresa's tenacious endeavour to recover her lost province proved unsuccessful, although in the Seven Years' War (*q.v.*) she was near success.

Austrian Silesia.—The history of Austrian Silesia is shortly told. It was combined with Moravia until 1849, when it was created a separate Crownland. In 1918 the Germans of Silesia claimed the right of self-determination, but their country was attributed to Czechoslovakia. The frontiers of Teschen (*q.v.*), which was disputed by Czechs and Poles, had to be drawn by the Allied Powers. By the law of 1927, the old Austrian Silesia became a federal province of the Czechoslovak State.

Prussian Silesia.—Prussian Silesia, on annexation, was reorganized completely. The old local institutions were abolished, and the country became an integral part of Prussia. Frederick II., who visited it yearly and appointed a special Minister for Silesia, introduced many important reforms and laid the foundations for its industrial development, in particular reviving the old mining and weaving industries. In 1815 Silesia was enlarged by a part of Lusatia, and henceforward developed very rapidly with the increasing importance of coal. It became highly industrialized, large mining areas and industrial towns, the latter with an almost wholly German population, alternating with agricultural districts inhabited by Polish peasantry.

THE PARTITION OF UPPER SILESIA

On the re-creation of the Polish State in 1918 the question of the attribution of Upper Silesia, with its great mineral wealth and mixed population of 2,280,902, became one of great importance. It was decided and provided by Article 88 of the Treaty of Versailles (1919) that the inhabitants of Upper Silesia should be called upon to decide by plebiscite whether they would belong to Germany or Poland (except in the purely German districts of Falkenberg, Grotthau, Neisse, part of Neustadt and Hultschin), the supreme authority in the area meanwhile being vested in an Inter-Allied commission consisting of one representative of France, Great Britain and Italy respectively. On Feb. 1, 1920, Allied troops occupied the plebiscitary district; local German officials were subordinated to the Inter-Allied authorities, and the German police replaced by a special polling police, composed half of German-speaking and half of Polish-speaking inhabitants.

The Plebiscites.—On the whole, the collaboration of the Inter-Allied control and the German officials proved satisfactory. Both the Poles (under Korfanty) and the Germans opened an active canvassing campaign; and the Poles, after previous excesses, attempted on Aug. 19, 1920, to seize the country by force, and order was not restored for several weeks. The Polish terrorism revived when the date of the plebiscite was announced for March 20, 1921, reaching a climax before the plebiscite, and recommencing after it. Bands, chiefly recruited from Congress Poland, usurped authority. The poll showed 717,122 votes for Germany and 483,514 for Poland. In 664 districts there was a German, in 597 a Polish majority. Practically all the towns voted for Germany. There was a Polish majority in the administrative districts of Rybnik, Pless, Beuthen, Tarnowitz and Gross-Strehlitz. The Inter-Allied Commission proved unable to agree on the allocation of the disputed regions, the French representative (who had from the first been accused of tacitly supporting the Poles) wishing to allot the whole of southern and eastern Upper Silesia to the Poles, while the British and Italian representatives wished to apportion the industrial region to Germany. Protracted diplomatic negotiations between Paris, London and Rome led to no result. At the end of April a report became current that the Council of Ambassadors had given only the districts of Rybnik and Pless to Poland; whereupon in May, Korfanty, at the head of a force armed and reinforced from Poland, occupied the whole south-eastern part of Upper Silesia, nominated himself dictator of these districts, took over the administration, and treated even the Allied officials so curtly that they were obliged to vacate the regions occupied by the Poles, except the larger towns. A further Polish advance was prevented, after severe fighting, by the German defence force, composed of Upper Silesians and volunteers from other parts of the Reich, under Gen. Hofer.

After fruitless attempts to negotiate with Korfanty, the Allies dispatched reinforcements of French and British troops to Upper Silesia. Lengthy negotiations were carried on with the German defence force, and British troops had, by June 20, re-occupied the larger towns, the Poles commanding the rural districts. Korfanty now lost control over his bands, which plundered the villages; work in many mines and ironworks stopped and the industrial district suffered severe losses.

THE DECISION OF THE LEAGUE OF NATIONS

After prolonged and open disagreement between the Allied Powers, France wishing to assign the whole industrial region to Poland, Great Britain to leave all except the south-east corner, with Pless and Rybnik, to Germany, it was decided, Italy and Japan supporting the British view, to entrust the decision to a commission of the Council of the League of Nations. This commission was ultimately constituted by the representatives of Japan (chairman), Brazil, China, Spain and Belgium. An award, published on Oct. 20, 1921, assigned to Poland at least 75% of the aggregate material wealth of the country. In order to guarantee the continuity of the economic life of the region during a provisional period of readjustment, and to provide for the protection of minorities, the commission recommended that a general convention be concluded between Germany and Poland, so as to place Upper Silesia under a special régime during the transitional period, and that an advisory "Upper Silesian Mixed Commission" should be set up, together with an arbitral tribunal for settling private disputes occasioned by the temporary measures.

The provisional or transitional period was to be 15 years. During that period: (1) Railway and tramway systems, privately owned or municipal, to continue under the terms of their concessions, and the German State railways to be put under a joint system of operation. Railway rates to be uniform; the State insurance of employees in the Silesian railway system to be undertaken by that system; a single accounts office to be set up for the whole system; expenses of new construction to be charged to a separate account, and borne by the State in whose territory it was carried out; the working capital for operation to be lent by the German State, and interest charged to the account of this system; profits or deficits to be divided between the two countries in proportion to the length of line and amount of traffic belonging to each. (2) The German mark was to be the only legal unit of currency, and Poland was to recognize the rights of the Reichsbank for a period not exceeding 15 years, but by agreement the two Governments might modify this arrangement earlier. (3) While the German monetary system was maintained in the Polish zone, the postal, telegraph and telephone charges should be in German currency. (4) The customs frontier should coincide with the political frontier, and the German and Polish customs law should apply, with certain exceptions.

For six months incoming goods from other countries, on which German or Polish duties had been paid previously to the partition, should cross the frontier without duty. For 15 years, natural products originating or coming from one of the two zones of the plebiscite area, and destined for consumption in the other, should cross the frontier free of duty. For six months, raw, half-manufactured and unfinished products of industrial establishments in one zone, destined for industrial establishments in the other, should cross free of duty; and this should continue for 15 years when the products, as finished, were intended for free importation into the country of origin. Natural or manufactured products originating in the Polish zone should, on importation into the German customs territory, be exempt from duty for three years from the date of the frontier-delineation. As regards export, the two countries should facilitate for 15 years the export of such pro-

ducts as were indispensable for industry in either zone. (5) Poland was to permit, for 15 years, the exportation to Germany of the products of the coal-mines in the Polish zone, and Germany similarly to Poland in respect of the mines in the German zone. (6) For the 15 years, any inhabitant regularly domiciled or occupied in the plebiscite area should receive a "circulation permit," free of payment, enabling him to cross the frontier without other formalities. (7) Generally, the two countries should respect private rights.

A German-Polish conference met at Geneva on Nov. 23, 1921, and a detailed convention was signed on May 15, 1922. On the whole, the industrial provisions suggested by the League worked unexpectedly smoothly. The prosperity of Polish Silesia was greatly furthered by the British coal strike of 1926. On the German side there was a tendency to transfer capital from Silesia to the Ruhr. A curious difficulty arose when the three-year duty-free period expired, owing to the world glut of coal. Germany was anxious to stop the free imports at the earliest date, while Poland wished for their continuance. This difference was a major obstacle to the conclusion of a German-Polish commercial treaty. An appeal by the German Government to the Permanent Court of International Justice on May 15, 1925, against Polish action in expropriating a nitrate factory at Chorzow, and certain landed estates, resulted in a decision by the Court generally in favour of Germany (May 25, 1926).

SILESIA, a province of Czechoslovakia, covering an area of 1,708 sq.m., stretches along the north-eastern flank of the Jeseník Mts. across the lowland of the Upper Oder to the northern slopes of the Jablunkovské hory (Lysá hora—4,346 ft.). A tongue of Moravia along the right bank of the Oder almost cuts it into two parts. Owing to its mountainous character and its slopes toward the north and north-east Silesia has a severe climate (Opava, 920 ft., Jan. 27·5° F, July 65·5° F), with a large seasonal range of temperature, and an annual rainfall of 20 to 30 ins., with a summer maximum. North-west of the Oder valley the surface formation is Carboniferous passing to eruptive rocks, but, in the valley and to the south-east, recent deposits, including loess, offer greater scope to agriculture. In the former region forestry, dairy-farming and sheep breeding together with the growth of fodder plants are typical, while in the latter cereals, fruit and poultry are the principal products. But Silesia is chiefly noted for its mineral wealth consisting of coal, iron-ore, lead, marble and slate. The foundation of its great and varied industrial activity is the coal of the Moravská Ostrava—Karvinná basin, the largest field in Czechoslovakia, giving a rich coking variety much of which goes to the large iron and steel foundries of Vítkovice nearby. Engineering and metallurgic industries concentrate on Moravská-Ostrava, the manufacture of agricultural machinery at Opava and Krnov and textiles, particularly woollen goods, at Krnov and Andělská Hora. Other industrial activities are chemicals (Vitkovice and Moravská-Ostrava), brewing and distilling.

In 1921 the population numbered 672,268, of whom 39·3% were German, 13·5% Poles and 46·3% Czechoslovaks. According to religion 84% were Roman Catholics, 9·6% Evangelicals, 2% Jewish and 3·6% belonged to the Czechoslovak church. A large measure of provincial autonomy is granted to the province which is counted with Moravia (*q.v.*), for purposes of representation in the national parliament.

See also Czechoslovakia; Moravia; and H. Cloos, *Der Gebirgsbau von Schlesien* (Berlin, 1922), and A. Fillunger, *Das Relief des Steinkohlengebirges von Mähr-Ostrau* (Vienna, 1903).

SILESIAN WARS, the name given to the contests between Austria and Prussia for the possession of Silesia. The first (1740–42) and second (1744–45) wars formed a part of the great European struggle called the War of the Austrian Succession (*q.v.*), and the third war (1756–62) similarly a part of the Seven Years' War (*q.v.*).

SILHOUETTE, ÉTIENNE DE (1709–1767), controller-general of France, was born at Limoges on July 5, 1709. He travelled extensively while still a young man and attracted attention by English translations, historical writings, and studies on the financial system of England. Successively councillor to the parlement of Metz, secretary to the duke of Orleans, member of the commission on delimitation of Franco-British interests in Acadia (1749), and royal commissioner in the Indies Company, he was named controller-general through the influence of the marquise de Pompadour on March 4, 1759. The court at first reposed a blind confidence in him, but, when he proposed a land-tax on the estates of the nobles and the reduction of pensions, a storm of opposition broke on the unfortunate minister. In allusion to the sacrifices which he demanded of the nobles, even the conversion of their table plate into money, *silhouette* became the popular word for a figure reduced to simplest form. Silhouette was driven from office in 1759 and withdrew to Brie-sur-Marne. He died on Jan. 20, 1767.

For a list of his writings *see* Quérard, *France littéraire*, ix. 138. A *Testament politique*, published under his name in 1772, is apocryphal. *See* J. P. Clement and A. Lemoine, *M. de Silhouette* (Paris, 1872); M. Guillaumat-Vallet, *Le Contrôleur-Genéral Silhouette et ses reformes en matière financière* (1914).

SILHOUETTE, the shadow outline of an object, usually a profile, obtained by projecting the shadow on to a sheet of white paper, tracing in the outline and afterwards filling in with a dark colour. About 1750 it became popular to have profile portraits cut out of black paper with scissors and mounted.

SILICA, in chemistry, the name ordinarily given to amorphous silicon dioxide, SiO_2. This chemical compound is widely and most abundantly distributed in nature, both in the free state and in combination with metallic oxides, constituting about 60% of the solid crust of the earth. Free silica constitutes the greater part of sand and sandy rocks; when fairly pure it occurs in the large crystals which we know as quartz (*q.v.*), and which, when coloured, form the gem-stones amethyst, cairngorm, cat's-eye and jasper. Tridymite (*q.v.*) is a rarer form, crystallographically different from quartz, and cristobalite is still rarer. Amorphous forms also occur: chalcedony (*q.v.*), and its coloured modifications agate, carnelian, onyx and sard, together with opal (*qq.v.*) are examples. Amorphous silica can be obtained from a silicate (a compound of silica and a metallic oxide) by fusing the finely powdered mineral with sodium carbonate, decomposing the sodium silicate thus formed with hydrochloric acid, evaporating to dryness to convert the colloidal silicic acid into insoluble silica, and removing the soluble chlorides by washing with hot water. On drying, the silica is obtained as a soft white amorphous powder, insoluble in water and in all acids except hydrofluoric; it dissolves in hot solutions of the caustic alkalis and to a less extent in alkali carbonates. It melts at 1,710° C, and in the electric furnace it may be distilled, the vapours condensing to a bluish-white powder. The melting point is not that of amorphous silica or ordinary quartz, for above 870° C this is unstable and is converted to tridymite; this in turn becomes unstable above 1,470° C, being then converted into cristobalite, and it is this form which is stable at the melting point. Under the very high pressures prevailing during the crystallization of igneous rocks, however, the limit of stability of quartz would be greatly raised, since its density (2·65) is greater than that of tridymite (2·3), and this probably accounts for the comparative rarity of the latter in spite of the rocks having crystallized at above 1,000° C. On the crystal structure of these forms of silica *see* Sir W. H. Bragg and R. E. Gibbs, *Proc. Roy. Soc.*, 1925–26; R. W G. Wyckoff, *Amer. J. Sci.*, 1925.

Quartz which has been heated above 575° etches differently from ordinary quartz and is therefore called β-quartz, the un-

heated variety being α. Since quartz crystals have no plane or centre of symmetry, they can exist in two forms which rotate the plane of polarization of light in opposite directions and are related to one another as an object and its image.

Silicates.—These compounds are to be regarded as salts of silicic acid, or combinations of silicon dioxide and metallic basic oxides; they are of great importance since they constitute the commonest rock-forming and many other minerals, and occur in every petrographical species. The parent acid, silicic acid, was obtained by T. Graham by dialysing a solution of hydrochloric acid to which sodium silicate had been added, a colloidal silicic acid being retained in the dialyser. This solution may be concentrated until it contains about 14% of silica by open boiling, and this solution on evaporation in a vacuum gives a transparent mass of metasilicic acid of approximate composition, H_2SiO_3. The colloidal solution is a tasteless liquid having a slight acid reaction; it gradually changes to a clear transparent jelly, which afterwards shrinks on drying. This coagulation is brought about very quickly by salts, especially those of multivalent metals. (*See* COLLOIDS.) The natural silicates may be regarded as falling into five classes, viz., orthosilicates, derived from $Si(OH)_4$; metasilicates, from $SiO(OH)_2$, disilicates, from $Si_2O_3(OH)_2$; trisilicates, from $Si_3O_5(OH)_2$; and basic silicates. These acids may be regarded as derived by the partial dehydration of the ortho-acid. Another classification is given in METALLURGY; a list of mineral silicates is given in MINERALOGY, and for the synthetical production of these compounds, *see* also PETROLOGY.

Certain naturally occurring silicates, *e.g.*, kaolin, and specially prepared amorphous silica, have the power of absorbing colouring matters from oils and thus improving their appearance.

Solutions of sodium silicate containing excess of silica ($SiO_2:Na_2O>1$) are used as adhesives and possess great advantages over ordinary adhesives in certain cases, *e.g.*, sticking paper to metals.

SILICON, a non-metallic chemical element. It is not found in the uncombined condition, but in combination with other elements it is, with the exception of oxygen, the most widely distributed and abundant of all the elements. It is found in the form of oxide (silica), either anhydrous or hydrated, as quartz, flint, sand, chalcedony, tridymite, opal, etc., but occurs chiefly in the form of silicates of aluminium, magnesium, iron, and the alkali and alkaline-earth metals, forming the chief constituent of various clays, soils and rocks. It has also been found as a constituent of various parts of plants and has been recognized in the stars. The element (symbol Si, atomic number 14, atomic weight 28·06, isotopes 28, 29, 30) exists in two forms, one amorphous, the other crystalline. The older methods used for the preparation of the amorphous form, namely the decomposition of silicon halides or silicofluorides by the alkali metals, or of silica by magnesium, give an impure product, but if a small proportion of magnesia is added in the last case, the product is of about 96% purity. The crystalline form may be prepared by heating potassium silicofluoride with aluminium, by heating silica with magnesium in the presence of zinc, or by volatilizing the amorphous variety from an electric furnace. A somewhat impure silicon (containing 90–98% of the element) is made by heating coke and sand in an electric furnace, the coke being present in insufficient quantity to form carborundum (*q.v.*), or by heating silica and carborundum similarly. The crystalline solid has specific gravity about 2·4, and the amorphous about 2·35; the melting points are about 1,450° C.

Amorphous silicon is a brown powder, the crystalline variety being grey, but differing according to the method of preparation. The specific heat varies with the temperature, from 0·136 at −39° C to 0·2029 at 232° C. Silicon is attacked rapidly by fluorine at ordinary temperature, and by chlorine when heated in a current of the gas. It undergoes a slight superficial oxidation when heated in oxygen. It combines directly with many metals on heating, whilst others merely dissolve it. It decomposes ammonia at a red heat, liberating hydrogen and yielding a compound containing silicon and nitrogen. It reduces many non-metallic oxides. It is only soluble in a mixture of hydrofluoric and nitric acids or in solutions of the caustic alkalis, in the latter case yielding hydrogen and a silicate:

$$Si+2KHO+H_2O=K_2SiO_3+2H_2,$$

a reaction which has been utilized for the large-scale production of this gas for military balloons. On fusion with alkaline carbonates and hydroxides it undergoes oxidation to silica which dissolves in excess of alkali yielding alkaline silicates.

Hydrides.—When hydrochloric acid reacts with magnesium silicide (produced by heating together two parts of magnesium and one part of silica), a spontaneously inflammable mixture of hydrogen and various hydrides of silicon is formed. By condensing the latter in liquid air and fractionating the resulting solid, A. Stock and his collaborators have obtained four "silanes" in a state of purity: (1) SiH_4, monosilane or silicomethane, m.p. −185° C, b.p. −42°, is a colourless gas which is very stable at the ordinary temperature and not spontaneously inflammable. (2) Si_2H_6, disilane or silicoethane, m.p. −132·5°, b.p. −15°, is stable at ordinary temperatures but decomposes below 300° and inflames in air; it reacts vigorously even with carbon tetrachloride, forming hydrogen chloride, silicon and carbon. (3) Si_3H_8, trisilane or silicopropane, m.p. −117°, b.p. 53°, is somewhat unstable at ordinary temperatures. (4) Si_4H_{10}, tetrasilane, m.p. −93·5°, b.p. 80–90°, is still more unstable. All the silanes reduce silver and copper salts, and they react with caustic alkalis to give a quantitative yield of hydrogen and silicate, *e.g.*, $Si_2H_6+4NaOH+2H_2O=2Na_2SiO_3+7H_2$. By direct reaction with bromine, or, better, by reaction with hydrogen bromide in the presence of aluminium bromide, they give a series of compounds in which the hydrogen is replaced successively by bromine, and these in turn react with water to give oxy-compounds; *e.g.*, bromo-monosilane yields disiloxane; $2SiH_3Br+H_2O=2HBr+(SiH_3)_2O$; and dibromosilane gives siloxane, SiH_2O, which polymerises rapidly to $(SiH_2O)_n$. For further details of these and related compounds, the works of A. Stock (*Berichte*, 1916 *et seq.*) should be consulted.

Only one oxide of silicon, namely the dioxide or silica, is definitely known (*see* SILICA) although SiO has been described.

Halides.—*Silicon fluoride,* SiF_4, is formed when silicon is brought into contact with fluorine; or by decomposing a mixture of acid potassium fluoride and silica, or of calcium fluoride and silica with concentrated sulphuric acid. It is a colourless, strongly fuming gas with suffocating smell and solidifies at −97° C. It is decomposed with great violence when heated in contact with either sodium or potassium. It combines directly with ammonia to form the compound $SiF_4{\cdot}2NH_3$, and is absorbed by dry boric acid and by many metallic oxides. Water decomposes it into silicofluoric acid and silicic acid: $3SiF_4+3H_2O=2H_2SiF_6+H_2SiO_3$, hydrogen fluoride being an intermediate product. It combines directly with acetone and with various amines.

Silicon fluoroform, $SiHF_3$, obtained by O. Ruff and Curt Albert by decomposing titanium fluoride with silicochloroform in sealed vessels at 100–120° C, is a colourless gas which may be condensed to a liquid boiling at −80·2° C (melting point about −110° C). It is very unstable, decomposing slowly, even at ordinary temperatures, into hydrogen, silicon fluoride and silicon:

$$4SiHF_3=2H_2+3SiF_4+Si.$$

It burns with a pale-blue flame forming silicon fluoride, silicofluoric acid and silicic acid. It is decomposed readily by water, alcohol and ether, yielding respectively silicofluoric acid, H_2SiF_6, ethyl orthosilicate, $Si(OC_2H_5)_4$, and ethyl orthosilicoformate, $SiH(OC_2H_5)_3$.

Silicofluoric or hydrofluosilicic acid, H_2SiF_6, is obtained as shown above, and also by the action of sulphuric acid on barium silicofluoride, or by absorbing silicon fluoride in aqueous hydrofluoric acid. The concentrated solution deposits a hydrated form, $H_2SiF_6{\cdot}2H_2O$. The anhydrous acid is not known, since on further heating alone or in aqueous solution it gradually decomposes into silicon fluoride and hydrofluoric acid.

Silicon chloride, $SiCl_4$, was prepared by J. J. Berzelius by the action of chlorine on silicon, and is also obtained when an intimate mixture of silica and carbon (or sulphur) is heated in a stream of chlorine and the products of reaction fractionated. It

is a very stable colourless liquid which boils at 58° C. Oxygen attacks it only at very high temperatures. When heated with the alkali and alkaline earth metals it yields silicon and the corresponding metallic chlorides. Water decomposes it into hydrochloric and silicic acids. It combines directly with ammonia gas to form $SiCl_4 \cdot 6NH_3$, and it also serves as the starting point for the preparation of numerous organic derivatives of silicon. By the action of acetylacetone on silicon tetrachloride a complex siliconium chloride $Si(C_5H_7O_2)_3Cl$ is produced, which gives rise to well-defined series of double salts such as $Si(C_5H_7O_2)_3AuCl_4$, $Si(C_5H_7O_2)_3FeCl_4$, and $[Si(C_5H_7O_2)_3]_2PtCl_6$. Silicon hexachloride, Si_2Cl_6, is formed when silicon chloride vapour is passed over strongly heated silicon; or by the action of chlorine or mercuric chloride on the corresponding iodo-compound. It is a colourless fuming liquid which boils at 146–148° C. It is decomposed by water, to give silico-oxalic acid, $Si_2O_4H_2$. *Silicochloroform*, $SiHCl_3$, is formed by heating crystallized silicon in hydrochloric acid gas at a temperature below red heat, or by the action of hydrochloric acid gas on copper silicide, the products being condensed by liquid air and afterwards fractionated. It is a colourless liquid which boils at 33° C. It fumes in air and burns with a green flame. It is decomposed by cold water with the formation of silicoformic anhydride, $H_2Si_2O_3$. Higher chlorides up to Si_6Cl_{14} are known.

The bromo-compounds resemble the corresponding chloro-compounds.

Silicon tetraiodide, SiI_4, is formed by passing iodine vapour mixed with carbon dioxide over strongly-heated silicon; the iodo-compound condenses in the colder portion of the apparatus and is purified by shaking with carbon bisulphide and with mercury. It crystallizes in octahedra which melt at 120·5° C and boil at 290° C. It is decomposed by alcohol:

$$SiI_4+2C_2H_5OH=SiO_2+2C_2H_5I+2HI.$$

The *hexaiodide*, Si_2I_6, obtained by heating the tetraiodide with finely divided silver to 300° C, crystallizes in hexagonal prisms which exhibit double refraction; it is soluble in carbon bisulphide, and is decomposed by water and also by heat, in the latter case yielding the tetraiodide and the di-iodide, Si_2I_4, an orange solid not soluble in carbon bisulphide. *Silicoiodoform*, $SiHI_3$, is formed, together with silicon tetraiodide, by the action of hydrogen and hydriodic acid on silicon. It is also obtained by the action of hydriodic acid on siliconitrogen hydride suspended in carbon disulphide, or by the action of a benzene solution of hydriodic acid on trianilino-silicon hydride:

$$SiH(NHC_6H_5)_3+6HI=SiHI_3+3C_6H_5NH_2 \cdot HI.$$

It is a colourless, strongly refracting liquid, which boils at about 220° C with slight decomposition.

Siliconitrogen hydride, SiNH, is a white powder formed with silicon amide when ammonia gas (diluted with hydrogen) is brought into contact with the vapour of silicochloroform at −10° C. *Trianilino-silicon hydride*, $SiH(NHC_6H_5)_3$, is obtained by the action of aniline on a benzene solution of silicon chloroform. *Silicon amide*, $Si(NH_2)_4$, is obtained as a white amorphous unstable solid by the action of liquid ammonia on silicon chloride. It is readily decomposed by water:

$$Si(NH_2)_4+2H_2O=4NH_3+SiO_2.$$

Above 0° C it decomposes thus; $Si(NH_2)_4 - 2NH_3+Si(NH)_2$.

Silicon sulphide, SiS_2, is formed by heating amorphous silicon with sulphur; it crystallizes in needles which rapidly decompose when exposed to moist air. By heating crystallized silicon with boron in the electric furnace, H. Moissan and A. Stock obtained two borides, SiB_3 and SiB_6, as stable crystalline solids.

Organic Derivatives of Silicon.—The organic derivatives of silicon resemble the corresponding carbon compounds except in so far that the silicon atom is not capable of combining with itself to form a complex chain to the same extent as the carbon atom. Many of the earlier-known silicon alkyl compounds were isolated by Friedel and Crafts and by Ladenburg, the method adopted consisting in the interaction of the zinc alkyl compounds with silicon halides or esters of silicic acids:

$$SiCl_4+2Zn(C_2H_5)_2=2ZnCl_2+Si(C_2H_5)_4.$$

The greatest advances have taken place with the application of the Grignard reagent (*q.v.*):

$$C_2H_5MgBr+SiCl_4 \rightarrow C_2H_5SiCl_3+MgBrPh \rightarrow$$
$$Ph(C_2H_5)SiCl_2+MgBrC_3H_7 \rightarrow Ph(C_2H_5)(C_3H_7)SiCl,$$

and by similar means F. S. Kipping (1907) was able to prepare phenylbenzylethylpropylsilicane $(C_6H_5)(C_7H_7)(C_2H_5)(C_3H_7)Si$, which he converted to sulphobenzylethylpropylsilicyl oxide, $(SO_3H \cdot C_6H_4 \cdot CH_2 \cdot SiEtPr)_2O$, and this was resolved into its *d*- and *l*- forms. (*See* STEREOCHEMISTRY.)

Silicon tetramethyl, $Si(CH_3)_4$ (tetramethyl silicane), and silicon tetraethyl, $Si(C_2H_5)_4$, are both liquids. *Triethyl silicol*, $(C_2H_5)_3Si \cdot OH$, is a true alcohol. *Silicon tetraphenyl*, $Si(C_6H_5)_4$, a solid melting at 231° C, is obtained by the action of chlorobenzene on silicon tetrachloride in the presence of sodium (Fittig's reaction). *Silicomesoxalic acid*, $HO \cdot OSi \cdot Si(OH)_2 \cdot SiO \cdot OH$, formed by the action of moist air on octachloro-trisilane, Si_3Cl_8, is very unstable, and hot water decomposes it with evolution of hydrogen and formation of silicic acid. *Silicobenzoic acid*, $C_6H_5 \cdot SiO \cdot OH$, results from the action of dilute aqueous ammonia on phenyl silicon chloride, $SiPhCl_3$ (obtained from magnesium phenyl bromide and silicon tetrachloride). It is a colourless solid which melts at 92° C. For organic derivatives of silicon *see* F. S. Kipping (*Journ. Chem. Soc.*, 1907 *et seq.*).

SILICON CARBIDE is one of the small class of solid compounds containing only non-metallic elements. It does not occur in nature, but was discovered accidentally in 1871 by Acheson, who gave it the name carborundum (*q.v.*). On account of its extreme hardness (next to diamond on Mohs's scale), its abrasive value was soon recognized, and it remains the first in importance, as it was the first in time, of commercially produced artificial abrasives (*q.v.*). It often appears as greenish, bluish, or brownish translucent or opaque crystals, but is generally seen as a greyish-brown powder, being of most industrial use in this form. Chemically it has the composition SiC (hardness, 9; sp.gr. 3·2). Its crystal structure is the same as that of the diamond, only with alternate carbon atoms replaced by silicon atoms. This fact is doubtless connected with its extreme hardness.

Silicon carbide is made by heating a mixture of 35% coke (C), 53% sand (SiO_2), 10% sawdust and 2% salt (NaCl). The furnace is rectangular, about 30 ft. long, 10 ft. wide, and 10 ft. high; and the electrodes are bundles of thick carbon rods passing through thick brick walls at the ends of the furnace. The space between the carbons of the electrodes is packed tightly with graphite, the charge of coke, sand, sawdust and salt is filled in up to the level of the centre of the electrodes, and a trench is made in it to hold small coke running longitudinally from one pole to the other. A further charge is then added and heaped up above the level of the top of the furnace. The brick walls are separated from the charge by a thickness of fine coke. An alternating current of about 6,000 amperes at 230 volts is switched on, and as the resistance diminishes, the current is regulated so as to be kept at 20,000 amperes and 75 volts. After about 48 hours the current is stopped, and after a day's cooling the furnace is carefully unpacked, and a layer of some 18 in. of nearly pure crystallized silicon carbide is found, together with layers of graphite and of partially converted material. Special precautions are required in starting and stopping the current (some thousands of kilowatts). The substance produced by this process resists the action of even the strongest acids, and the action of air or of sulphur at high temperatures. The crude product can therefore be treated with hot sulphuric acid to purify it.

Silicon carbide forms a more or less porous crystalline mass, which shows some well-defined hexagonal plates. Although harder than artificial corundum, it is less tough and has a different fracture. The properties of silicon carbide make it the most efficient abrasive for working on materials of low tensile strength such as cast iron, copper, aluminium, marble, granite and pearl. Carborundum paper, made like emery paper, is now largely used

in place of garnet paper in American shoe factories, and finds a market in other directions as well. It is also used in the form of grinding wheels, and coated cloth, and as loose grains. Silicon carbide is also extensively used in the manufacture of high temperature refractories. The amorphous carbide, which was at first a waste product, has been tried, it is reported with success, as a lining for steel furnaces, since it is said not to be affected by iron or iron oxide at a white heat.

See F. B. Jacobs, *The Abrasive Handbook* (1928).

SILICON STEEL. Invented by Sir Robert Hadfield in 1889, this alloy is a most important member of the family of steel alloys, and led to the perfection of what is termed low hysteresis steel, so largely used in the manufacture of generators, transformers, and other electrical apparatus. It should be explained that the term hysteresis is applied to the tendency of magnetic materials to remain in any magnetic state which already exists. This leads to considerable loss of energy when the magnetic state is changed. Silicon steel is superior to iron itself in magnetic qualities, and improves in that respect with use. Therefore it makes an ideal core for electrical transformers, and its use saves millions of tons of coal every year.

Silicon steel is made by heating steel containing 2½% to 4% of silicon to a temperature of about 1,000° Centigrade. It is then cooled, reheated to about 800°C., and cooled again. Hadfield made the first electrical transformer employing his silicon steel as recently as 1903. (*See* STEEL [ALLOYS].)

SILISTRA, the chief town of the department of Durostor in Rumania and the see of an archbishop, situated on a low-lying peninsula projecting into the Danube, 81 m. below Ruschuk. Pop. (1928) 17,600. The town was formerly a fortress of great strength, occupying the north-east corner of the famous quadrilateral (Ruschuk, Silistra, Shumen, Varna), but its fortifications were demolished in accordance with the Berlin Treaty (1878). In the town is a large subterranean cavern, the *Houmbata,* which served as refuge for its inhabitants during frequent bombardments. The principal trade is in cereals; wine and wood are also exported. The town also contains saw mills. It is surrounded by fine vineyards, some 30 kinds of grapes being cultivated, and tobacco is grown. Apiculture is extensively practised and there are large market-gardens in the neighbourhood. The soil of the department is fertile, but lacking in water; the inhabitants have excavated large receptacles in which rain-water is stored. A considerable area is still covered with forest, to which the region owes its name of Deli Orman ("the wild wood"); there are extensive tracts of pasturage, but cattle-rearing declined in 1880–1910. A large cattle-fair, lasting three days, is held in May.

Silistra was the Durostorum of the Romans, the Δρίστρα of the Greeks. It was one of the most important towns of Moesia Inferior and was successively the headquarters of the legio I. (Italica) and the legio XI. (Claudia). It was defended by the Bulgarian tsar Simeon (*q.v.*) against the Magyars and Greeks in 893. From 967-971 it was held by the Russian prince Sviatoslav, whom the Byzantine emperor Nicephorus Phocas had summoned to his assistance. It was then held successively by the Byzantines, Petchenegs, Byzantines again, and Bulgars, till captured in 1388 by the Turks. A few years later it seems to have been in the possession of the Walachian prince Mircea, but in 1416 it passed finally into the hands of the Turks. Silistra flourished under Ottoman rule; Hajji Khalifa describes it as the most important of all the Danubian towns; a Greek metropolitan was installed here with five bishops under his control and a settlement of Ragusan merchants kept alive its commercial interests. In the Russo-Turkish wars of the nineteenth century it played a most important part. It was assigned to Bulgaria in 1878, and to Rumania, after the second Balkan War, in 1913.

SILIUS ITALICUS, in full TITUS CATIUS SILIUS ITALICUS (A.D. 25 or 26–101), Latin epic poet. His birthplace is unknown. He was a renowned forensic orator, and got a bad name under Nero by acting as prosecuting counsel in the "trials" of Nero's victims. He was consul in the year of Nero's death (68), and is mentioned by Tacitus as having been one of two witnesses who were present at the conferences between Vitellius and Flavius Sabinus, the elder brother of Vespasian, when the legions from the East were marching rapidly on the capital. The life of Silius after his consulship is well depicted by the younger Pliny:—"He conducted himself wisely and courteously as the friend of the luxurious and cruel Vitellius; he won repute by his proconsulship of Asia, and obliterated by the praiseworthy use he made of his leisure the stain he had incurred through his active exertions in former days. In dignity and contentment, avoiding power and therefore hostility, he outlived the Flavian dynasty, keeping to a private station after his governorship of Asia." Silius was a great student and patron of literature and art, and a passionate collector. His heroes were Cicero and Virgil; he possessed Cicero's villa at Tusculum, and the estate in Campania where he spent his years of retirement contained Virgil's tomb. He imitated Virgil in writing an epic, and Cicero in passing much of his time in philosophic conversation, especially with Epictetus. Stricken at the end of his life with an incurable tumour he followed Stoic practice in starving himself to death, keeping a serene and cheerful spirit to the end.

Whether Silius committed to writing his philosophic dialogues or not, we cannot say. Chance has preserved to us his epic poem entitled *Punica,* in 17 books, and comprising some 14,000 lines. In choosing the Second Punic War for his subject, Silius had, we know, many predecessors, as he doubtless had many followers. In justice to Silius and Lucan, it should be observed that the mythologic poet had a far easier task than the historic. In a well-known passage Petronius pointedly describes the difficulties of the historic theme. A poet, he said, who should take upon him the vast subject of the civil wars would break down beneath the burden unless he were "full of learning," since he would have not merely to record facts, which the historians did much better, but must possess an unshackled genius, to which full course must be given by the use of digressions, by bringing divine beings on to the stage, and by giving generally a mythologic tinge to the subject. The Latin laws of the historic epic were fixed by Ennius, and were still binding when Claudian wrote. They were never seriously infringed except by Lucan.

To seize the moments in the history, however unimportant, which were capable of picturesque treatment; to pass over all events, however important, which could not readily be rendered into heroics; to stuff out the somewhat modern heroes to something like Homeric proportions; to subject all their movements to the passions and caprices of the Olympians; to ransack the poetry of the past for incidents and similes on which a slightly new face might be put; to foist in by well-worn artifices episodes, however strange to the subject, taken from the mythologic or historic glories of Rome and Greece,—all this Silius knew how to do. He did it all with the languid grace of the inveterate connoisseur, and with a simplicity foreign to his time, which sprang in part from cultivated taste and horror of the venturesome word, and in part from the subdued tone of a life which had come through the reigns of Caligula, Nero and Domitian. The more threadbare the theme, and the more worn the machinery, the greater the need of genius. Two of the most rigid requirements of the ancient epic were abundant similes and abundant single combats.

No writer has ever been more correctly and more uniformly judged by contemporaries and by posterity alike. Only the shameless flatterer, Martial, ventured to call his friend a poet as great as Virgil. But the younger Pliny gently says that he wrote poems with greater diligence than talent, and that, when according to the fashion of the time, he recited them to his friends, "he sometimes found out what men really thought of them." Nor has he been more admired in modern times, since Poggio discovered him. Yet, by the purity of his taste and his Latin in an age when taste was fast becoming vicious and Latin corrupt, by his presentation to us of a type of a thousand vanished Latin epics, and by the historic aspects of his subject, Silius merits better treatment from scholars than he has received. The general reader he can hardly interest again.

The raw material of the *Punica,* which covers 17 books, was supplied in the main by the third decade of Livy, though Silius

may have consulted other historians of the Hannibalic war. Such facts as are used are generally presented with their actual circumstances unchanged, and in their historic sequence. The general plan of the epic follows that of the *Iliad* and the *Aeneid*. Its theme is conceived as a duel between two mighty nations, with parallel dissensions among the gods. Scipio and Hannibal are the two great heroes who take the place of Achilles and Hector on the one hand and of Aeneas and Turnus on the other, while the minor figures are all painted with Virgilian or Homeric pigments. Hannibal, however, who at the outset is clearly designed as an incarnation of cruelty and treachery, clearly forces his greatness on the poet during the course of the book, while Scipio is never anything but a cardboard Achilles. The best drawn of the minor characters are Fabius Cunctator, an evident copy of Lucan's Cato, and Paullus, the consul killed at Cannae, who fights, hates and dies like a genuine man. All the well-known episodes of Homer and Virgil are there; Hannibal has a wonderful shield and Scipio a revelation of the greatness of Rome. The descriptions of the numerous battles are made up in the main, according to epic rule, of single combats—wearisome sometimes in Homer, wearisome oftener in Virgil, painfully wearisome in Silius. The different component parts of the poem are on the whole fairly well knit together, and the transitions are not often needlessly abrupt; yet occasionally incidents and episodes are introduced with all the irrelevancy of the modern novel. The interposition of the gods is, however, usually managed with dignity and appropriateness.

As to diction and detail, we miss, in general, power rather than taste. The metre runs on with correct smooth monotony, with something always of the Virgilian sweetness, though attenuated, but nothing of the Virgilian variety and strength. The dead level of literary execution is seldom broken by a rise into the region of genuine pathos and beauty, or by a descent into the ludicrous or the repellent. There are few absurdities, but the restraining force is trained perception and not a native sense of humour, which, ever present in Homer, not entirely absent in Virgil, and sometimes finding grim expression in Lucan, fails Silius entirely. The address of Anna, Dido's sister, to Juno compels a smile. Though deified on her sister's death, and for a good many centuries already an inhabitant of heaven, Anna meets Juno for the first time on the outbreak of the *Second* Punic War, and deprecates the anger of the queen of heaven for having deserted the Carthaginians and attached herself to the Roman cause. Hannibal's parting address to his child is also comical: he recognizes in the "heavy wailing" of the year-old babe "the seeds of rages like his own." But Silius might have been forgiven for a thousand more weaknesses than he has if in but a few things he had shown strength. The grandest scenes in the history before him fail to lift him up; his treatment, for example, of Hannibal's Alpine passage falls immensely below Lucan's vigorous delineation of Cato's far less stirring march across the African deserts.

But in the very weaknesses of Silius we may discern merit. He at least does not try to conceal defects of substance by contorted rhetorical conceits and feebly forcible exaggerations. In his ideal of what Latin expression should be he comes near to his contemporary Quintilian, and resolutely holds aloof from the tenor of his age. Perhaps his want of success with the men of his time was not wholly due to his faults. His self-control rarely fails him; it stands the test of the horrors of war, and of Venus working her will on Hannibal at Capua. Only a few passages here and there betray the true silver Latin extravagance. In the avoidance of rhetorical artifice and epigrammatic antithesis Silius stands in marked contrast to Lucan, yet at times he can write with point. Regarded merely as a poet he may not deserve high praise; but, as he is a unique specimen and probably the best of a once numerous class, the preservation of his poem among the remains of Latin Literature is a fortunate accident.

The poem was discovered in a ms., possibly at Constance by Poggio, in 1416 or 1417; from this now lost ms. all existing mss., which belong entirely to the 15th century, are derived. A valuable ms. of the 8th or 9th century, found at Cologne by L. Carrion in the latter part of the 16th century, disappeared soon after its discovery. Two *editiones principes* appeared at Rome in 1471; the principal editions since have been those of Heinsius (1600), Drakenborch (1717), Ernesti (Leipzig, 1791) and L. Bauer (1890). The *Punica* is included in the second edition of the *Corpus poëtarum Latinorum* (1905). A useful *variorum* edition is that of Lemaire (Paris, 1823). Recent writing on Silius is generally in the form of separate articles or small pamphlets; but *see* H. E. Butler, *Post-Augustan Poetry* (1909), chap. x. For his life, the authorities are Pliny, III., 7; Tac., *Hist.* III. 65. Martial, *passim.*

SILK, ARTIFICIAL, or RAYON. A textile, of which cellulose is the principal raw material, designed to resemble natural silk. The method of preparing artificial silk filaments is always first to get the filament-forming substance into solution or colloidal suspension in a liquid medium, then to force this solution or suspension through an orifice and, finally, to "set" or solidify the viscous filament thus produced, either by evaporating away the liquid with a current of dry air (dry process) or by making use of a coagulating or setting bath into which the filament exudes from the orifice and there solidifies (wet process). The former dry process is similar, in principle, to the spinning processes of silk worms and spiders, the idea of copying which was suggested by R. A. F. de Réaumur in 1734 and by Robert Hooke (*Micrographia*) in 1664.

Cellulose is now always the primary raw material and appears likely to remain the only one (*see* CELLULOSE). Many others, however, have been tried: the silk fibroin of waste silk itself has been used, but the amount of this raw material is, of course, quite insufficient and the insect does the same work better than the factory. Casein, gelatine, egg albumen, agar agar, carragheen and glass are also among the materials that have been seriously considered, but not one of them gives a product as useful as that obtained by the mercerising of cotton, originated by John Mercer in 1844 and perfected by H. A. Lowe in 1889; hence they have not been employed industrially.

The age of artificial silk really begins with Comte Hilaire de Chardonnet (1839–1924) who, as pointed out by C. F. Cross, was a student at the École Polytechnique under Pasteur at the time when his momentous investigations into silk-worm disease culminated; and without any doubt this was the source of the inspiration that started Chardonnet on his life work. After 30 years of effort he took out his first patent for collodion, nitro— or Chardonnet silk in 1884–85. In the meantime, however, the development of electric lighting had interested Swan, Crookes, Robertson, Weston, Swinburne, Wynne, and Powell, and others in improving the production of suitable carbon filaments for incandescent electric lamps. Their particular problem was to get cellulose into a condition that would allow of its being squirted through a hole in a plate and, ultimately, to carbonize the filament thus obtained, which could then be sealed into a bulb: in this purpose they either used strong solutions of zinc chloride or of Schweizer's reagent (cuprammonium hydroxide) in which to dissolve or disperse cotton wool or they dissolved nitrocellulose in alcohol-ether or glacial acetic acid. J. W. Swan on Dec. 4, 1884, produced a fabric which he described as "artificial silk" and this is the first recorded use of the designation; it was a collodion material and in the following July he described also his method of denitrifying it with ammonium sulphide, which is still the method used. But there were great technical difficulties in adapting these early methods to the factory scale, and the costs of production were higher than the cost of real silk. The development of artificial silk on an extensive industrial scale began with the discovery of viscose by C. F. Cross and E. J. Bevan in 1892 and the invention of the Topham spinning box in 1900 by C. F. Topham, who with C. H. Stearn had taken up the spinning problem with Cross & Bevan; and it is the low costs of the viscose process and the perfection of the Topham box as a spinner that have, technically, made artificial silk the success it is. By 1910 viscose silk had made a strong start with 20% of the world's output; by 1927 it accounted for 84% of a total output of at least 280 million pounds.

The Four Industrial Processes.—There are four industrial processes in operation, namely, (*a*) Chardonnet, collodion or nitro-silk, (*b*) cuprammonium silk, (*c*) viscose silk, (*d*) acetate silk. The silk obtained by the first three processes is regenerated or reverted cellulose; the silk of the fourth process is an acetate-ester compound of cellulose or, more correctly, a mixture of ace-

tate-esters. All of them, therefore, use cellulose as the primary raw material.

Since the cellulose has to be dissolved or dispersed in a fluid medium, it is obvious that the length of the fibre is of no importance whatever and, theoretically, any sort of cellulose might therefore be used; actually, however, it is a fact derived from experience that high quality in the final product is greatly dependent upon special quality in the raw material. Two, and only two, sorts of raw material are of any account, namely, cotton linters and high grade bisulphite wood pulp.

Cotton Linters.—In the process of ginning, the short seed hairs or staples of the ripe cotton seed capsule are separated from the longer staples, as being not worth spinning for the cotton industries; these short staples are known as linters. The market price of linters is (1927) about 5d. a pound. The quantity available is approximately $\frac{1}{15}$ of the total output of raw cotton or, say, 400,000 tons (1927); the nitro-cellulose industries (explosives, Chardonnet silk, lacquers, films, plastic masses, etc.), consume about 70,000 tons a year; cuprammonium, viscose and acetate silks use a further quantity at present impossible to estimate with any degree of precision but which may be also about 70,000 tons. It is evident, however, that the supply of this raw material is likely to be adequate to all demands for as long as can be foreseen. The crude linters are purified with appropriate machinery, by freeing them from seeds, husks and other mechanical admixture, then by boiling them 2–4 hours at 100°–120°C. with 2–5% alkali solution (NaOH or Na_2CO_3); they are then washed free of alkali and bleached with bleaching powder solution (2–6% of active chlorine being usually consumed); and, finally, well washed and dried. This material is very pure cellulose and it is characterized chemically as being 95% or more of alkali-resistant or alpha-cellulose; that is to say, when it is treated with 17·5% sodium hydroxide (mercerising solution), under standard conditions, approximately 95% remains undissolved.

Sulphite Wood Pulp.—The viscose industry, almost exclusively, and the cuprammonium process to a considerable extent use wood pulp as the primary raw material; the quantity thus consumed (1927) is about 130,000 tons which is less than 2% of the world's total output of pulp, and it is obvious, therefore, that the artificial silk industries are never likely to have any difficulty in obtaining all the wood pulp required and that these industries will never be the cause of any serious increase of the world's wood consumption.

Of the processes in use for preparing pulp from wood only the bisulphite process is used to prepare pulp intended for viscose, and spruce (*Picea excelsa*) is the usual wood used; all experience has shown that other pulps are not so good for the purpose. But it has to be a special grade, specially prepared, and its price is £2–£5 a ton above that of ordinary bisulphite pulps. This special grade of pulp is characterized by a high content of alkali-resistant or alpha-cellulose, approximating to 90% of the dry weight, and it should contain no more than 1–2% of beta-cellulose, *i.e.*, cellulose soluble in alkali and reprecipitated by acetic acid, under standard conditions; the remainder of the cellulose (gamma-cellulose) is soluble in alkali and not reprecipitated by acetic acid. The ash content must also be not more than 0·3%; it would otherwise be likely to cause obstruction of the minute orifices of the spinnerettes, when the spinning stage is reached, by precipitation of calcium salts. The ether-soluble (resin) constituents should not exceed 0·6% and the so-called "copper number" (*i.e.*, the percentage of cuprous copper, proportional to the percentage of oxy- and hydro-cellulose present, formed by reaction with a standard alkaline solution of cupric sulphate), should not exceed 2–3. Finally the state or condition of aggregation of the cellulose fibre is of importance because some pulps react easily with sodium hydroxide (mercerising) solution in the first stage of the factory process, whereas other pulps, in spite of favourable chemical composition as determined by laboratory analysis, do not; constant, uniform quality in this respect is essential and the requirements of different factories vary to some extent and give the pulp maker some difficult problems accordingly. But the pulp maker has, on the whole, attained a high level of perfection though his process is still based on empirical practice mainly.

The other raw materials required are ordinary products of the heavy chemical industries, but they must be of high grade purity. An abundant supply of pure, soft water is absolutely essential; it must be softened, if necessary, and filtered; the quantity required daily in gallons approximates to 0·5×(lb. of annual output), *i.e.*, a factory producing 2,000,000 lb. annually will consume about 1,000,000 gallons a day.

Chardonnet, Nitro- or Collodion Silk.—For the artificial silk industry a product consisting mainly of a mixture of esters with a nitrogen content approximating to 10–11·5%, known as collodion, and soluble in alcohol-ether is most suitable and, in practice, it is commonly prepared by nitrating purified, oven-dried cotton linters with a mixture approximating to 17–19% water, 60% sulphuric acid, and 20–23% nitric acid.

The cotton is immersed in about 45–80 times its own weight of the mixture, this large quantity of liquid being used with the object of ensuring uniform nitration of the cotton. In practice the nitration is regulated within the temperature limits 20–40°C. because a lower yield and lower quality of product—correlated with degradation of the cellulose—is obtained if the temperature is allowed to rise freely. In these circumstances the time required for the nitration is usually about 1–2 hours. It is worthy of notice that wood-pulp cellulose, containing no more than 90% of alpha or undegraded cellulose to 10% of degraded, semi-celluloses on the dry weight, does not give a good collodion silk because the nitration process, even when carefully controlled, degrades some of the cellulose; and if there is already present an initial proportion of degradation products, as there is in even the best pulp, the final product is, of course, proportionately more degraded. And all experience proves that high quality in every cellulose product, whether prepared by nitration or by other treatment, is always correlated with a high proportion of undegraded cellulose. Hence, cotton linters are used in preference to wood pulp.

After completion of the nitration, the surplus acid is removed by squeezing out the nitrated cotton in presses and by centrifuging; the recovered acid is worked up and used again or sold for other industries, *e.g.*, superphosphate. The washing of the nitrated cotton is commonly done with cold and with hot water and it is also broken into shreds in a bronze breaker or hollander (iron being attacked by the acid residues present). Before the final washing, the nitro-cotton may be bleached, if necessary, with bleaching powder solution and finally it is dried in special drying chambers with a current of warm air at about 40–45°C., vacuum drying being also sometimes employed.

The nitro-cellulose thus obtained has retained much of the appearance of the original cotton; its specific gravity is very similar; it is less hygroscopic than cotton, and it is soluble in alcohol-ether and in acetone. If the nitration has not been properly controlled there may be traces of unnitrated cellulose present; the ash content should be no higher than that of the original cellulose and it will probably contain a trace of sulphur, present as sulphate, attributable to the formation of a trace of sulphate-ester in the nitration process. Acids saponify the nitro-cellulose to give the whole of the cellulose, considerably degraded, as a fine powder; with alkalies, also, saponification proceeds progressively, with ultimate production of degraded cellulose.

Spinning.—The nitro-cellulose is dissolved in a mixture of, usually, two of alcohol to three of ether to make a 20–30% solution for spinning; other solvents have been tried, such as acetone, acetic acid, etc., but without real success. For dissolving the nitro-cellulose, kneaders and revolving cylinders are used and a clear solution of the strength required is obtained in about eight hours; it is filtered and passed into tinned steel or tinned copper storage tanks, where air bubbles are removed by vacuum and the viscosity gradually increases to a point at which it is suitable for spinning. Both "dry" spinning and "wet" spinning are in use, but the former method appears to be now more usual.

In "dry" spinning the alcohol-ether solvent is evaporated and the filament, on issuing from the orifice of the spinnerette, dried by a current of warm air. The air, laden with alcohol and ether vapours, is then passed through condensing towers with the object

of recovering the alcohol and ether; but success in this is imperfect and the losses account for much of the rather high costs of this process as compared with those of the viscose process. It will be readily understood that it is technically by no means easy to condense, with high efficiency, the vapour of a low boiling liquid like ether when diluted with the large volume of air necessary to make the drying of the filament effective in the short distance between the orifice and the spool on to which it has to be reeled.

In "wet" spinning, on the other hand, which was Chardonnet's original method and which is still in use, the filament issues from the orifice of the spinnerette into a setting bath containing water in which it is immersed and which coagulates the nitro-cellulose and dissolves the alcohol-ether solvent. In this "wet" process nitro-cellulose solutions of lower concentrations and lower viscosities can be used and this allows filtration and spinning pressures to be lower; also it allows the so-called "stretch spinning" process to be used in which the filament, on issuing from the orifice of the spinnerette, is stretched and drawn out to a smaller diameter; the alcohol and ether can be also very easily recovered, by distillation, from the setting bath. But, in spite of such advantages, dry spinning gives the larger output per unit; this gives it the ultimate economic advantage and hence it has been gradually superseding the wet spinning process.

Denitration.—Nitro-cellulose is both inflammable and explosive, and therefore it is necessary to remove the nitro-groups from the spun nitro-cellulose and, thereby, to convert it back to cellulose. A great many reagents have been tried for this purpose but none has any advantages over the original sodium, ammonium or calcium sulphide solution first used by Swan in 1885 and universally used to-day. These sulphide baths have little or no adverse effect on the strength of the filaments and they are very cheap; denitration is carried to the point at which a small residue of about 0·05–0·1% of nitrogen remains in the filaments. The reactions involved are complicated and no satisfactory method of recovering the sulphur and nitrogen has been found; but the denitrated filament, in feel and in appearance, is undoubtedly one of the nearest approaches to real silk yet attained and that is the real reason of the early success of this process and of the continued and increasing demand for Chardonnet silk. In 1910 the output of this silk was about 2½ million pounds and 48% of the total output; in 1927 it was about 8·5 million pounds and 3% of the total output; thus it has maintained a satisfactory growth in competition with the stupendous growth of the viscose silk output.

Cuprammonium Silk.—The cuprammonium process was patented by Depeisses in 1890, shortly before his death; but others took it up and it was developed at first in France, later in Germany and in England, and brought to a high level of technical perfection. It was developed with the object of establishing a more economical process than the nitro-cellulose process, especially by avoiding the use of the heavily excise-taxed alcohol and ether; but the position it has attained and which it holds is mainly due to its suitability for the "stretch-spinning" process, which allows of the production of a filament of extreme fineness and high quality that also dyes very well.

This process, in fact, gives a product which is perhaps the nearest approach there is to real silk and which has always appealed to the more exacting consumers. The output of this silk, which was about 2 million pounds in 1910 and about 36% of the total output, had increased to about 16 million pounds in 1927, about 6% of the total output; its future no doubt depends to some extent upon the possibility of improving the qualities of viscose silk, more particularly in respect of fineness of filament and in feel, appearance and strength.

In this process the cellulose raw material and the chemicals must be of highest grade and purity. On the Continent bleached cotton linters and in Great Britain bleached wood pulp are generally used; it was said that linters gave a higher textile strength in the finished product but it has been established that wood pulp gives a product in every respect at least as good as that obtained from linters and with the advantage of the lower price. E. Schweizer in 1857 discovered that the deep blue solution obtained by dissolving copper hydroxide in ammonia, called "Schweizer's Reagent," dissolves or disperses cellulose, from which it can be precipitated by solutions of acids, alkalies, certain salts, glycerine, sugar and other substances. The process generally in use was as follows:—the cellulose was cut, broken and beaten with water in a collander and then filtered off, centrifuged and added moist to the Schweizer reagent. This reagent was usually prepared as follows:—copper turnings and 25% ammonia solution are mixed in a tower, through which cooled air is circulated; the mixture is cooled by a cold water jacket so that the temperature does not rise above 5°C., otherwise some of the ammonia will be oxidized and less cellulose will dissolve in the resulting solution (containing some ammonium nitrite thus formed); in 18–24 hours the copper will have dissolved and its concentration is then increased by adding to it a strong solution of copper sulphate to which an equivalent quantity of sodium hydroxide solution is finally added. This procedure is, in practice, found to give the highest attainable concentration and to be capable of taking up as much as 12–13% of cellulose or more. It is found that the cellulose dissolves or disperses in this reagent more quickly and gives a higher concentration, when the temperature is kept down, by cooling, to 10°C.

Latterly, the more usual procedure has been to treat the cellulose with 17% sodium hydroxide (mercerising) solution, whereby so-called alkali-cellulose, such as is used in the viscose process, is obtained; after being squeezed dry and torn into crumbs it is then immersed in saturated, cold copper sulphate solution, which causes copper hydroxide to be precipitated within the mass of the cellulose and with which it is thus most intimately incorporated; the surplus copper sulphate solution is then squeezed out and the mass is immersed in strong ammonia solution, in which it dissolves or disperses rapidly to give a high concentration of cellulose. This procedure is evidently a definite advance on its predecessors.

It is customary to add up to 2% of cane sugar, glucose or tartaric acid to the spinning solution, which gives a more favourable sheen to the finished product and also, apparently, diminishes the degradation of the cellulose. The spinning solution is filtered through a nickel or unrustable steel, fine mesh screen and submitted to evacuation for the removal of air bubbles and surplus ammonia. It is then spun by the "stretch spinning" process, for which it is especially suitable, into a setting bath of water at 35° C. to which small additions of acids, alkalies, sugar, etc., are sometimes made and from which the air is partially removed by heating, evacuating and cooling, so that air bubbles may not get occluded in and "set" with the filament. The setting quality of the water is due to the gradual removal of the ammonia by diffusion into and solution in the water, and the cellulose can be thus very gradually thrown out and congealed.

In the "stretch spinning" process, as its name implies, the filament is submitted to stretching during this gradual coagulation; and considerable extension, with corresponding diminution of diameter, thus ensues, with the result that even when a spinnerette with comparatively large orifices is employed the finest filaments can be spun, surpassing natural silk in fineness. The spun product obtained is treated with 1% hydrochloric acid solution at 40–50° C. to remove copper residues and then well washed until there is not the faintest trace of surplus acid remaining, the presence of which, ultimately, would greatly diminish the strength, by formation of hydro-cellulose. Many attempts have been made to recover the ammonia and copper waste products, but with comparatively small success, in respect of cost; they are greatly diluted in the setting bath and that, of course, is the main difficulty. The copper is usually recovered by electrolysis; the ammonia is usually run to waste. The Bemberg Co. of Barmen, which has played a leading part in perfecting this process, has recently patented a method of recovering the ammonia by precipitating it with magnesium phosphate, which forms an insoluble double magnesium ammonium phosphate from which the ammonia can be easily recovered.

Viscose Silk.—The viscose reaction was patented by C. F. Cross and E. J. Bevan in 1892, and in 1927 it provided a world's output of about 235 million pounds and 84% of the total output.

Bisulphite wood pulp cellulose most usually, and cotton linters to a small extent, are used for this process; the bleached cellulose is first treated with 17% (mercerising) sodium hydroxide solution for two hours, the surplus solution is then squeezed out and the resultant alkali-cellulose is torn into crumbs, which are matured for 24 hours or more in a closed vessel; 60 parts of carbon bisulphide per 100 parts of air-dry cellulose are then added and the cellulose crumbs gradually swell and become deep-orange coloured and gelatinous in three to four hours' time. After the further addition of an appropriate quantity of sodium hydroxide solution and water a viscous solution or dispersion called viscose, of 7% strength or more, is obtained, which is allowed to "ripen" for a variable period, usually one to two days, until its viscosity has diminished, so that it has become suitable for spinning. All these details must be standardized empirically to ensure uniformity of final product and there are minor variations of procedure related to minor variations of conditions, including quality of raw materials and other factors; this is an industry in which experienced scientific control is essential at every step. The viscose is filtered and spun by the wet process, from spinnerettes immersed in a "setting" bath containing, *e.g.*, a solution of sulphuric acid and sodium sulphate, which congeals the filament and throws out some free sulphur, a portion of which remains in the filament, from which it has to be removed. The yarns produced are washed with water and marseille soap, dried, reeled into skeins and immersed in a bath of three to four parts of sodium sulphide per 1,000 water at 70°C. for about 20 minutes, which dissolves out the sulphur; then, after being washed, the yarns are immersed in a very weak bleaching solution and in a very weak acid solution; the yarns, now pure white, are washed, immersed in a weak bath of sodium bisulphite solution (to destroy residual bleach), washed, immersed in very dilute acetic acid solution and again washed and dried; finally, washed with soap (which improves the feel) and carefully dried and conditioned so as to contain up to 10% moisture.

Every step of this remarkable process has been scrutinized and, in the course of its history, modifications have been suggested and tried, almost infinite in number, most of which are of little more than academic interest. For example, all sorts of substances have been suggested as advantageous additions, in modification of the "setting bath"; sugar, glycerine, lactic acid, citric acid, tartaric acid and so on, and some are commonly used to-day, *e.g.*, sugar and glycerine, which appear to have a favourable influence on the coagulation and improve the feel of the final product. The influence of variations of composition of the "setting bath" in relation to its effects on the cross section of the filament have been studied in great detail and especially by A. Herzog (*Leipziger Monatsschrift f. Textilindustrien*, Bd. 9, 1926). The ideal cross section for a filament is the nearest attainable approximation to a circle, with close, minutely serrated edge (like a circular saw with minute teeth); this particular section is the most favourable for uniform light reflection from the surface and, hence, the most even colour effect after dyeing; and it is, of course, also the section that will give the greatest tensile strength. This section is greatly modified by variations of concentration in the "setting" bath; thus a solution of 12% sulphuric acid and about 1–8% sodium sulphate will give a very favourable cross section, from 8–16% sodium sulphate not quite so good, and 16–32% a very badly distorted cross section; 10–12% sulphuric acid alone gives a good cross section, as does also 20% ammonium chloride, but with an edge not so favourably serrated; and so on. These facts determine the composition and concentrations of the "setting" baths used. In general terms it is true, not only of viscose but of the other artificial silks too, that the form of the cross section is related to the composition of the substance of the filament, the manner of its coagulation, including the actual composition of the setting bath, and other variable factors; so that the microscopic examination of cross sections will often give much information of composition, quality, and origin.

The changes that occur in the so-called "ripening" of viscose have been the subject of much study, and much remains to be done before it can be said to be well understood. The sodium xanthogenate or xanthate (viscose) formed, is certainly a monoester derivative of cellulose which is in the form of a colloidal, emulsoid dispersion in sodium hydroxide solution. After formation, the viscosity diminishes and, after a day or two, reaches a level at which it remains for some days before it increases again, until a final setting to a coagulated mass of hydrated cellulose, with elimination of a watery solution containing sulphur compounds. These changes are retarded and the keeping quality of the viscose increased, within limits, by increasing the excess of sodium hydroxide present; the addition of salts, of course, as in the "setting" bath, has the opposite effect as does also rise of temperature. This sequence of changes is known in other emulsoid colloids, too, and is designated "synaeresis." In the first stage of diminution of viscosity there is a diminution of particle size (increase of dispersion) and in the later stages an increase of particle size with an increase of viscosity and final coagulation. This later stage has been described also, in terms of chemistry, as an increase of the C_6-unit of the cellulose molecule first to the C_{12}-unit and then to the C_{24}-unit, for each OCSSNa-unit of the sodium-ester group. Depending on these facts there is at least one method of determining the degree of "ripeness" of viscose which is of value in the factory. The principle of the method is that the addition of a definite quantity of a coagulating salt solution will coagulate the viscose slowly if the ripening has not progressed very far and rapidly if it has progressed far; the time taken for coagulation, under standard conditions, is thus a measure of the degree of ripeness.

The waste liquors of the viscose industry contain acids, sulphur compounds and alkali mostly, in considerable dilution and, being of low initial cost, they are not worth recovering. They are apt to be a noxious trade effluent, the disposal of which is one of the first factors for consideration in selecting the site for a factory. The 17% mercerising sodium hydroxide solution, pressed out from the pulp in the first stage of preparing viscose, contains hemicelluloses, resin, etc., and therefore cannot be used again and no process of regenerating it or recovering the soda economically has been successful. But the cheapness of the substances used in this process makes it possible to ignore the value of the waste products and that is the great economic advantage this process has over the others.

Acetate Silk.—Cellulose was acetylated by Schutzenbugen in 1865, and Franchimont in 1879 discovered the advantage of adding a catalyst to hasten the action. C. F. Cross and E. J. Bevan patented the first feasible industrial process in 1895. They acetylated cellulose with acetyl chloride in presence of magnesium or zinc acetate, as catalyst. In the meantime, however, the other silk processes were being developed industrially with considerable success and it was really the World War which brought the acetate process into industrial prominence. During the War a large factory for the manufacture of cellulose acetate as dope for aircraft, for which it is valuable because of its low inflammability and its shrunk-finish effect on the wing-fabric, was erected at Spondon, Derbyshire, at a cost of 7¾ millions sterling; at the end of the War this installation was turned to use for the manufacture of artificial silk by the acetate process. Simultaneously the earlier difficulties of dyeing acetate silk were overcome about 1920 and improvements were made in the process for recovering the acetone, used as solvent in the process of dry spinning the acetate. By 1927 the output of acetate silk amounted to about 20 million pounds and about 7% of the world's total output. It has been thought by some that ultimately it may largely displace viscose silk, though there is no obvious sign of this.

Cellulose acetate is prepared by treating cotton linters containing about 5% moisture, with not less than three times their weight of acetic anhydride, with a suitable quantity of glacial acetic acid, as diluent, and with about 10% of sulphuric acid, as catalyst. During the first hour or so the temperature should not be allowed to rise above 25°C and it is best that it should be much lower; thereafter the temperature is raised and eventually the whole of the cellulose dissolves or disperses in the fluid. Industrially, samples are taken from time to time during the warming and dissolving process, and they are put into

water which throws out the acetate; this acetate is filtered, washed, and its solubility in acetone tested. When the solubility of a sample is satisfactory the warming up process is stopped and the crude product is thrown into water which precipitates the acetate as a white fibrous mass; it is filtered, washed, dried, and merchandized in that form. It dissolves or disperses in acetone to give a fluid of good spinning quality. This is the acetate known industrially as the "secondary" acetate, and it gives about 55–58% of acetic acid on saponification. The so-called "primary" acetate which gives up to 62·5% acetic acid on saponification, and is therefore the tri-acetate, is obtained by continuing the warming-up stage of dissolving or dispersing the cellulose, after acetylation, until it has ceased to be acetone-soluble and has become chloroform-soluble; it may be transformed back into the acetone-soluble, chloroform-insoluble, "secondary" acetate by partial saponification with 95% acetic acid at 40°–50°C. and especially in presence of a small amount of sulphuric acid as catalyst. The "secondary" acetate used for spinning is therefore evidently a mixture of acetate esters.

Dry spinning is the spinning process always used, and the recovery of the acetone vapours has been perfected to a very high efficiency; it is said that 90% and more of the acetone can be recovered by employing methods involving refrigeration and absorption by charcoal. In the acetate process the acetic anhydride and acetic acid are of course more expensive than the caustic soda and carbon bisulphide of the viscose process and the cotton linters more expensive than wood pulp; the acetic anhydride and the acid are practically irrecoverable; the acetone is, however, almost completely recovered. On the other hand, some of the acetic anhydride adds on to the cellulose in forming the ester, the yield of which is consequently about 30% greater than the weight of the original cotton linters; finally, any material spoilt in the spinning process, or later, can be merely re-dissolved and spun again, so that ultimate losses are reduced to the absolute minimum. Therefore the final cost of acetate silk is perhaps not so very much higher than that of viscose silk and is possibly no more than about twice as much.

The acetate process gives a very beautiful product, much less absorbent of moisture than any of the other artificial silks or real silk. This is sometimes spoken of as an advantage, but it is perhaps a doubtful one; for it is a special merit of wool and silk, as clothing, that they can absorb as much as 30% or more of moisture without becoming damp to the feel. In this respect, the other artificial silks have something of the same sort of advantage over acetate silk. Cellulose acetate is also an excellent electrical insulator and is now used a great deal for this purpose both as a wrapping, as real silk is used, and also as a lacquer; it also transmits ultra violet light better than, *e.g.*, glass and is therefore used as film for this special purpose.

Plant and Machinery.—The manufacture of artificial silk, as far as the production of the filaments, is a chemical industry, and the plant and machinery are therefore very much like that of other chemical industries. But every material has its own special qualities and properties requiring special adjustments and, therefore, though boiling kiers, bleaching apparatus, extractors, dryers, filter presses, shredders, mixers, agitators, washers, etc., are similar to those used in other industries they have some minor modifications of detail and arrangement which have been evolved in accordance with the demands of experience in this as in every other industry. The same is true of the textile processes of winding, skeining, weaving, knitting, dyeing, and finishing generally; ordinary textile processes, though the same in principle, have had to be adjusted to the special qualities and properties of artificial silk, and, in particular, the textile operative has to be trained to handle the material with the special care it demands.

The spinning processes are peculiar to this industry; they are of great interest and worthy of special description. As mentioned already there are two methods, namely, dry spinning and wet spinning, the essential difference of principle of which is as their names imply; in the former, the filament which exudes from the orifice of the spinnerette is solidified or dried by a current of warm, dry air, whereas in the latter the filament is solidified, congealed, or set by immersion in an appropriate solution which coagulates it.

Dry Spinning.—Dry spinning is the method employed in the collodion-silk and acetate-silk processes; the alcohol-ether solvent and the acetone solvent, respectively, are evaporated and the filament dried by a current of dry air, as will be readily understood from the scheme of one form of apparatus shown in fig. 1. The solution to be spun is ejected from the container, through the orifices of the spinnerette as a bundle of separate filaments which are dried by a counter current of warm, dry air passing upwards and carrying the vapours of the solvent away through the outlet; the filaments converge on passing round the pulley wheel, which is coupled with the winder, on to which the yarn is wound; the number of filaments in the yarn is, of course, determined by the number of orifices in the spinnerette. By a modification of this apparatus the filaments can be stretched so that from relatively large orifices relatively fine filaments may be produced; by another modification the parallel filaments can be twisted or this can be done on a separate machine, such as is used for twisting natural silk filaments into yarns. It is also possible to employ a vacuum to make evaporation the more effective, and gases, such as sulphurous acid and carbonic acid, have been also added to the current of air, though apparently with no very conspicuous advantage. It will be noticed that in this process the spinning is downwards; this is necessitated by the obvious advantage of using warm air, which of course circulates upwards, *i.e.*, in counter direction, and of allowing the air, when fresh, dry, and therefore most effective, to come first into contact with the almost dry portions of the filaments, which it thus dries under conditions of greatest advantage.

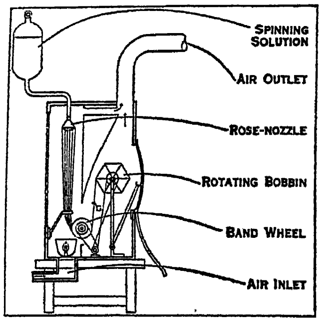

FIG. 1.—DRY SPINNING

Wet Spinning: Bobbin Spinning.—The principle of this method is illustrated in plan in fig. 2. The spinning solution is driven by a pump through a filter and the spinnerette orifices as filaments, into a setting bath, from which they are wound on to the bobbin, which also rotates in a setting bath. The filaments, as yet parallel, have to be subsequently twisted on a separate machine, such as is used for twisting natural silk; this disadvantage has led to the gradual and almost complete supersession of this method by the pot or centrifugal spinning box method due to C. F. Topham (1900), which was once very correctly described by C. F. Cross, of whom he was the colleague and coworker, as "a comprehensive solution of the main difficulties which had been encountered and a radical development of the industrial outlook in respect of mass production." The textile world has long marked the Topham box as a work of genius.

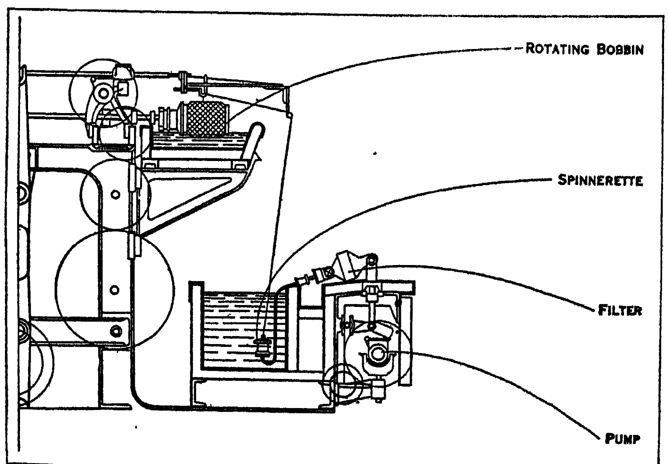

FIG. 2.—BOBBIN SPINNING

Topham Centrifugal Box Spinning.—This method is illustrated in fig. 3. The spinning solution is forced by a pump through a filter and the spinnerette orifices as filaments, into a setting bath, from which they are carried over the roller through a funnel, which is given an up and down motion by the reciprocating mechanism and thence into the Topham box, which is rotated at a high speed by a driving mechanism, electric or otherwise. Thus the filaments, spun into a yarn, are piled into a "cake" and, very important, given a much desired twist in the process of piling, the amount of which depends upon the speed of the delivery of the thread and of the revolving pot.

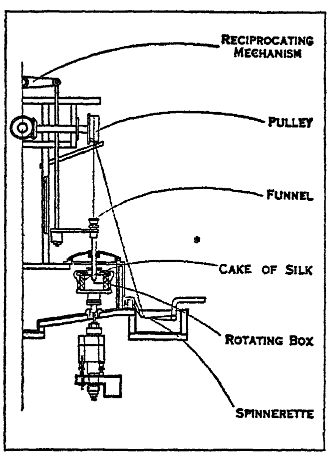

FIG. 3.—TOPHAM CENTRIFUGAL BOX SPINNING

Stretch-Spinning.—A modification of the bobbin and centrifugal box spinning methods allows of stretch-spinning, which originated in an observation due to W. P. Dreaper and H. K. Tompkins (1897), who noticed that stretching during coagulation much increased the sheen of the product. The stretch-spinning process now used, especially for the spinning of cuprammonium silk, was first developed by Thiele in 1901 from an earlier process due to Lehner in 1890. The principle of the method is illustrated in fig. 4. The filaments issuing from the spinnerette orifices pass through the funnel and, from its lower end, over the roller whence they pass to a winding mechanism. The setting fluid, water, circulates up to the level of the spinnerette and gradual coagulation accompanies the gradual diffusion and absorption

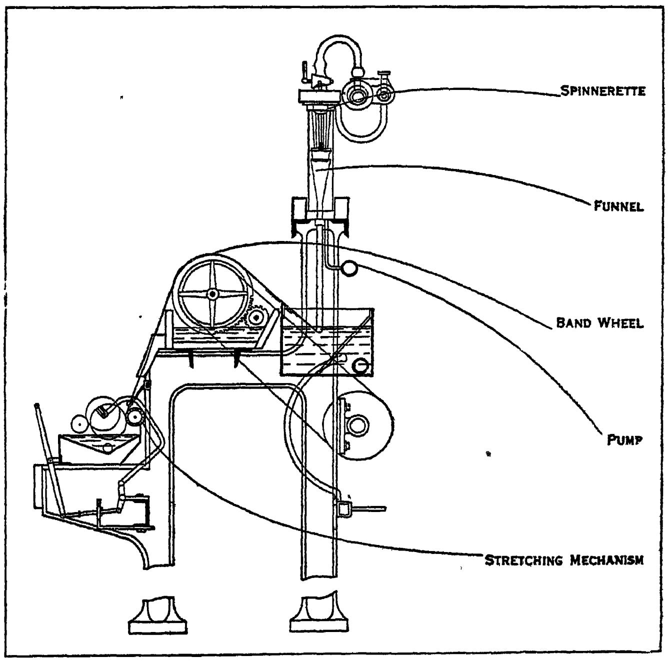

FIG. 4.—STRETCH SPINNING

of the ammonia from the exuding filament into the water; all the time this gradual coagulation is proceeding the filaments are moving towards the winding mechanism, which is pulling and stretching them, and they are thus drawn out to a very small diameter, which may even surpass that of natural silk. This process, most successfully applied to cuprammonium silk, has given it a special quality that is much esteemed by the more exacting consumers. It is, however, also possible to make viscose filaments as fine as natural silk and without employing stretch-spinners; the special advantage of stretch-spinning is to that extent of less importance than it was formerly.

Properties of Silks.—The products obtained from the collodion, cuprammonium and viscose processes, being all of them reverted or regenerated cellulose, are very similar in qualities and properties; the acetate is an ester, or mixture of esters, formed by addition of acetyl radicles to the cellulose molecules, and its qualities and properties are therefore differentiated. The apparent specific gravity of the three former is very close to that of ordinary cellulose (1·58), namely, about 1·52; that of the acetate is 1·33 and that of real silk 1·40. The qualities that are of outstanding interest and importance are the strength and elasticity; and especially by comparison with real silk. The following comparative figures show how much superior real silk still is and especially when wet; acetate silk is very little absorbent of moisture and is therefore not strictly comparable, but approximately it is nearly as strong wet as dry, though when dry it is not so strong as the other silks. It will be noticed that natural silk is about as strong wet as it is dry, and of great elasticity.

Class.	Denier.	Breaking strain, grams.		Extension %.	
		Dry.	Wet.	Dry.	Wet.
Collodion	5·0	9·6	5·1	13·0	8·9
Cuprammonium . . .	5·0	9·2	4·8	12·9	15·1
Viscose	5·0	12·1	6·0	15·1	12·2
Acetate	5·0	7·9	6·7	31·2	26·7
Silk	1·27	7·8	7·3	14·7	32·7

The artificial silks are not very elastic; that is to say that, after being stretched, they do not recover their original dimensions if the stretch is very much, and it has been well said that for half its breaking strain it acts like elastic and thereafter like perished rubber. The textile mill must adjust its methods accordingly, as also must the ultimate consumer.

Tendencies of the Industry.—In 1927 the viscose process dominated the situation by reason of the cheapness of the raw materials and because of viscose silk's good dyeing and finishing qualities. Much has been done to improve the lustre, which can be made very similar to that of real silk. Among the most interesting and promising of modified treatments is the Lilienfeld process (1926), according to which a coagulating bath containing more than 55% sulphuric acid gives filaments from viscose which have a tensile strength surpassing that of any other artificial thread and, in some cases, approaching or surpassing that of even cotton or real silk, and with the further advantage of resistance to alkalies and soap. The viscose process is so highly developed that it can easily produce filaments as fine as those of real silk, and demand and production are actually tending in the direction of very fine spinning.

The output of artificial silk in pounds weight has increased greatly since the World War; the increase in actual spinning is of course relatively much greater because the filament-denier is now much lower. The improvements have given increased strength, softer feel, and more silk-like appearance. Hollow filaments can be produced, and the best method appears to be by projecting the viscose containing a small proportion of added soluble carbonate into the usual acid setting bath with the addition of some other salts, such as zinc or magnesium sulphate, the action of which appears to be favourable; the action of the acid is evidently to form a gas bubble (carbon dioxide) in the filament which is elongated with the filament. These hollow fibres are very pliable and they have the "scroop" or rustle of real silk.

Artificial silk is produced in large and ever increasing quantities; its applications are probably still in their infancy and the limits of their future possibilities cannot be foreseen. Its use in combination with other textile materials has necessitated modified methods of weaving, dyeing, finishing, etc., which, in turn, have reacted on some of the related industries the main requirement of which, in general terms, is that the filaments and yarns must be free, in every stage of manufacture, to run smoothly, evenly and without jerks, because the elastic limits are not so favourable as

they are in natural fibres. Lubricants used in the textile industries with natural fibres, *e.g.*, sperm oil, white curd soap, olive oil and neat's-foot oil, mineral oil, compounded oil (mineral and vegetable), and soluble oils, are used also with artificial silks, and sizing materials such as starch, dextrine, gum tragacanth, and gelatin are similarly used. But loading and weighting materials are never employed, and this is a notable difference—by comparison with the natural silk industries particularly.

It is not unlikely that the greatest future use of artificial silk will be in combination with the natural fibres; there are already signs that this is possible. Thus, in combination with natural silk, and especially with the less expensive grades, the greater strength of the natural silk is a definite gain. Similarly, favourable combinations with cotton, especially mercerised cotton, and with wool are in ever increasing demand. The additional strength is important; the soft feel and absorbent quality of artificial silk are very advantageous for such uses as underclothing; and it is a curious fact that so far from competing with wool, for this use, artificial silk has in combination with it actually made wool more popular. For brocades and furnishings, generally, artificial silk on cotton warps and backings gives a favourable combination of beauty and strength. Admixtures with linen are just coming into use (1927).

For these purposes of admixture with other fibres, the so-called "staple fibre" is now in great demand. Each natural fibre has its own peculiar average staple length, whereas the artificial silk filament is, of course, of infinite length; therefore for spinning in admixture with natural fibres artificial silk is cut up into short length staples or "staple fibre." In this way 75% of staple fibre is now commonly spun into yarn with 25% cotton, wool or silk; carding instead of combing is the process employed and counts up to 80 threads per inch appear to be most in demand; many fabrics are equal in appearance to the loveliest that can be produced from pure natural silk and not far short in strength and weaving quality. Valuable effects are also obtained by skilful applications of dyeing principles; thus whereas the artificial silks (excepting acetate) react to dyes very much as cotton does, their reactions are different from those of silk and wool. Hence mixtures of artificial silk and natural silk (or wool) can be either dyed in the single or by cross dyeing and thus twist and marl effects can be obtained; the mixture is dyed for the artificial silk and the natural silk (or wool) remains undyed.

Acetate silk has presented some dyeing problems peculiar to itself which formerly greatly handicapped its use but which have been solved in a satisfactory way; the difficulty was that it would not take up dyes by the ordinary methods in use and the only method available was to treat it with alkali, to regenerate cellulose, whereby the special quality of the acetate was wholly sacrificed. There is now a large range of dyes available and the previous methods of dyeing have been entirely abandoned.

Related to the artificial silk industries are the manufacture of artificial wool and artificial horse hair, sheets, films, and tissues and plastic masses. The solutions used for spinning artificial silk from spinnerettes with, *e.g.*, 50 or more minute orifices, may be, of course, also spun from spinnerettes with one or more larger orifices and artificial horse-hair may be thus produced; or ribbon strips may be similarly made. The spinnerettes with fine orifices for artificial silk are usually made from alloys of gold, platinum and palladium, and glass is also used to some small extent; for spinning horse-hair and ribbons glass spinnerettes are employed.

These spinning solutions may be also made into sheets, films and tissues. Thus nitro-cellulose, frequently mixed with camphor and pigments, is made into celluloid sheets and moulded articles and also into photographic and cinema (inflammable) film; cellulose acetate is made into (non-inflammable) cinema film; viscose into a thin tissue known as cellophane, used as a food wrapper, and into film caps, often pigmented, much in use as a closure for bottles, especially by pharmacists, for which they are well suited because their great shrinkage during drying gives a very tight closure. Nitro-cellulose, mixed with softeners and pigments and dissolved in butyl or amyl acetate, is much used as a lacquer for motor car bodies and other high class out-door work; cellulose acetate similarly dissolved is the dope used for the wing fabric of aircraft, to which it gives a shrunk water-proof finish and for which the nitrate, being very inflammable, would be unsuitable.

Hitherto, the esters are the only derivatives of cellulose that have come into use in industry. Any derivative that can be brought into solution or dispersion would be usable in similar manner, and the ethers, especially, of which a very large number are known already and known to have valuable intrinsic qualities, could and would be used if they could be made at competitive prices. But the cost of preparing ethers is a good deal higher than the cost of preparing esters, though it is quite possible that some day there will be cheaper methods available. SILK AND SERICULTURE. Silk is a fibrous substance produced by many insects, principally in the form of a cocoon or covering within which the creatures are enclosed and protected during the period of their principal transformations; the webs and nests, etc., formed by spiders are also of silk. But the fibres used for manufacturing purposes are exclusively produced by the mulberry silk-moth of China, *Bombyx mori,* and a few other moths closely allied to that insect.

History.—According to native record the silk industry has existed in China from a very remote period. The empress, known as the lady of Si-ling, wife of a famous emperor, Huang-ti (2640 B.C.), encouraged the cultivation of the mulberry tree, the rearing of the worms and the reeling of silk. This empress is said to have devoted herself personally to the care of silkworms, and she is by the Chinese credited with the invention of the loom. A voluminous ancient literature testi-

fies to the antiquity and the importance of Chinese sericulture, and to the attention bestowed on it by royal and noble families. The Chinese guarded the secrets of their valuable art with vigilant jealousy; and there is no doubt that many centuries passed before the culture spread beyond the country of its origin. Through Korea a knowledge of the silkworm and its produce reached Japan, but not before the early part of the 3rd century. One of the most ancient books of Japanese history, the *Nihongi,* states that towards A.D. 300 some Koreans were sent from Japan to China to engage competent people to teach the arts of weaving and preparing silk goods. They brought with them four Chinese girls, who instructed the court and the people in the art of plain and figured weaving; and to the honour of these pioneer silk weavers a temple was erected in the province of Settsu. Great efforts were made to encourage the industry, which from that period grew into one of national importance. At a period probably a little later knowledge of the working of silk travelled westward. According to a tradition the eggs of the insect and the seed of the mulberry tree were carried to India by a Chinese princess concealed in the lining of her head dress. The fact that sericulture was in India first established in the valley of the Brahmaputra and in the tract lying between that river and the Ganges renders it probable that it was introduced overland from the Chinese empire. References in Sanskrit literature indicate however that a silk industry existed in India at about 1000 or possibly 4000 B.C. From the Ganges valley the silkworm was slowly carried westward and spread in Khotan, Persia and Central Asia.

The first notice of the silkworm in Western literature occurs in Aristotle, *Hist. anim.* v. 19 (17), 11 (6), where he speaks of "a great worm which has horns and so differs from others. At its first metamorphosis it produces a caterpillar, then a bombylius and lastly a chrysalis—all these changes taking place within six months. From this animal women separate and reel off the cocoons and afterwards spin them. It is said that this was first spun in the island of Cos by Pamphile, daughter of Plates." But long before this time raw silk must have begun to be imported at Cos, where it was woven into a gauzy tissue, the famous *Coa vestis,* which revealed rather than clothed the form.

Towards the beginning of the Christian era raw silk began to form an important and costly item among the prized products of the East which came to Rome. The silken textures which at first found their way to Rome were necessarily of enormous cost, and their use by men was deemed a piece of effeminate luxury. From an anecdote of Aurelian, who neither used silk himself nor would allow his wife to possess a single silken garment, we learn that silk was worth its weight in gold. Notwithstanding its price and the restraints otherwise put on the use of silk the trade grew. Under Justinian a monopoly of the trade and manufacture was reserved to the emperor, and looms, worked by women, were set up within the imperial palace at Constantinople. Justinian also endeavoured, through the Christian prince of Abyssinia, to divert the trade from the Persian route along which silk was then brought into the east of Europe. In this he failed, but two Persian monks who had long resided in China, and there learned the whole art and mystery of silkworm rearing, arrived at Constantinople and imparted their knowledge to the emperor. By him they were induced to return to China and attempt to bring to Europe the material necessary for the cultivation of silk, which they effected by concealing the eggs of the silkworm in a hollow cane. From the precious contents of that bamboo tube, brought to Constantinople about the year 550, were produced all the races and varieties of silkworm which stocked and supplied the Western world for more than twelve hundred years.

The silkworm took kindly to its Western home and flourished, and the silken textures of Byzantium became famous. At a later period the conquering Saracens obtained a mastery over the trade, and by them it was spread both east and west—the textures becoming meantime impressed with the patterns and colours peculiar to that people. They established the trade in the thriving towns of Asia Minor, and they planted it as far west as Sicily, as Sicilian silks of the 12th century with Saracenic patterns still testify. Ordericus Vitalis, who died in the first half of the 12th century, mentions that the bishop of St. Evroul, in Normandy, brought with him from Apulia in southern Italy several large pieces of silk, out of the finest of which four copes were made for his cathedral chanters. The cultivation and manufacture spread northwards to Florence, Milan, Genoa and Venice—all towns which became famous for silken textures in mediaeval times. In 1480 silk weaving was begun under Louis XI. at Tours, and in 1520 Francis I. brought from Milan silkworm eggs, which were reared in the Rhone valley. But it cannot be said that these industries were firmly established before Colbert in the 17th century encouraged the planting of the mulberry by premiums, and otherwise stimulated local efforts.

Into England silk manufacture was introduced during the reign of Henry VI.; but the first serious impulse to manufactures of that class was due to the immigration in 1585 of a large body of skilled Flemish weavers who fled from the Low Countries in consequence of the struggle with Spain then devastating their land. Precisely one hundred years later religious troubles gave the most effective impetus to the silk-trade of England, when the revocation of the Edict of Nantes sent simultaneously to Switzerland, Germany and England a vast body of the most skilled artisans of France, who planted in these countries silk-weaving colonies which are to this day the principal rivals of the French manufacturers. The bulk of the French Protestant weavers settled at Spitalfields, London—an incorporation of silk workers having been there formed in 1629. James I. used many efforts to encourage the planting of the mulberry and the rearing of silkworms both at home and in the colonies. Up to the year 1718 England depended on the thrown silks of Europe for manufacturing purposes, but in that year Lombe of Derby, disguised as a common workman, and obtaining entrance as such into one of the Italian throwing mills, made drawings of the machinery used for this process. On his return, subsidized by the government, he built and worked, on the banks of the Derwent, the first English throwing mill. In 1825 a public company was formed and incorporated under the name of the British, Irish and Colonial Silk Company, with a capital of £1,000,000, principally with the view of introducing sericulture into Ireland, but it was a complete failure, and the rearing of the silkworm cannot be said ever to have become a branch of British industry.

In 1522 Cortes appointed officials to introduce sericulture into New Spain (Mexico), and mulberry trees were then planted and eggs were brought from Spain. The Mexican adventure is mentioned by Acosta, but all trace of the culture had died out before the end of the century. In 1609 James I. attempted to reinstate the silkworm on the American continent, but his first effort failed through shipwreck. An effort made in 1619 obtained greater success, and, the materials being present, the Virginian settlers were strongly urged to devote attention to the profitable industry of silk cultivation. Sericulture was enjoined under penalties by statute; it was encouraged by bounties and rewards; and its prosecution was stimulated by rhapsodical rhymes like the following:

> Where Wormes and Food doe naturally abound
> A gallant Silken Trade must there be found.
> Virginia excels the World in both—
> Envie nor malice can gaine say this troth!

In the prospectus of Law's great *Compagnie des Indes Occidentales* the cultivation of silk occupies a place among the glowing attractions which allured so many to disaster. Onward till the period of the War of Independence bounties and other rewards for the rearing of worms and silk filature continued to be offered; and when the war broke out Benjamin Franklin and others were engaged in establishing a filature at Philadelphia. With the resumption of peaceful enterprise, the stimulus of bounties was again applied—first by Connecticut in 1783; and such efforts have been continued sporadically down almost to the present day. Bounties were last offered by the state of California in 1865–1866, but the state law was soon repealed, and an attempt to obtain state encouragement again in 1872 was defeated. About 1838 a speculative mania for the cultivation of silk developed itself with remarkable severity in America. It was caused principally through the

representations of Samuel Whitmarsh as to the suitability of the South Sea island mulberry (*Morus multicaulis*) for feeding silkworms; and so intense was the excitement that plants and crops of all kinds were displaced to make room for plantations of *M. multicaulis*. In Pennsylvania as much as $300,000 changed hands for plants in one week and frequently the young trees were sold two and three times over within a few days at ever-advancing prices. Plants of a year's growth reached the ridiculous price of $1 each at the height of the fever, which, however, did not last long, for in 1839 the speculation collapsed; the famous *M. multicaulis* was found to be no golden tree, and the costly plantations were uprooted. These endeavours to stimulate by artificial means have in scarcely any instance resulted in permanent success. In truth, raw silk can only be profitably brought to the market where there is abundant and very cheap labour—the fact that China, Japan, Bengal, Piedmont and the Levant are the principal producing localities making this plain.

The Silkworm.—The mulberry-feeding moth, *Bombyx mori*, which is the principal source of silk, belongs to the *Bombycidae*, a family of *Lepidoptera* in which are embraced some of the largest and most handsome moths. *B. mori* is itself an inconspicuous moth, of an ashy white colour, with a body in the case of the male not ½ in. in length, the female being a little longer and stouter. Its wings are short and weak; the fore pair are falcate, and the hind pair do not reach to the end of the body. The larva which is hairless, is of an ashy grey or cream colour, attains to a length of from 3 to 3½ in., and is slender in comparison with many of its allies. The second thoracic ring is humped, and there is a spine-like horn or protuberance at the tail. The common silkworm produces only one generation during the year where the seasons are defined, *e.g.*, Europe and the Near East; in Japan, the largest silk-producing country of the world, the race of silkworm is bivoltine, *i.e.*, reproduction takes place twice annually, while in parts of India and China reproduction is almost continuous and the races cultivated are called multivoltine; but the quality of the silk is in inverse ratio to the number of hatchings. The silkworm's natural food is the foliage of mulberry trees.

The silk glands or vessels consist of two long thick-walled sacs running along the sides of the body, which open by a common orifice—the spinneret or seripositor—on the under lip of the larva. As the larva approaches maturity these vessels become gorged with a clear viscous fluid, which, upon being exposed to the air immediately hardens to a solid mass. Advantage is taken of this peculiarity to prepare from fully developed larvae silkworm gut used for casting lines in rod-fishing, and for numerous other purposes where lightness, tenacity, flexibility and strength are essential. The larvae are killed and hardened by steeping some hours in strong acetic acid; the silk glands are then separated from the bodies, and the viscous fluid drawn out to the condition of a fine uniform line, which is stretched between pins at the extremity of a board. The board is then exposed to the sunlight till the lines dry and harden into the condition of gut. The preparation of gut is, however, merely an unimportant collateral manufacture. When the larva is fully mature, and ready to change into the pupa condition, it proceeds to spin its cocoon, in which operation it ejects from both glands simultaneously a continuous and reelable thread of 800 to 1,200 yd. in length, moving its head round in regular order continuously for three days or thereabouts. The thread so ejected forms the cocoon, and consists of filaments seriposited from two separate glands. Two other glands, named after their discoverer the glands of Filippi, secrete a glutinous or resinous substance, which is believed to serve the double purpose of helping the thin viscous threads through the spinneret and causing the two filaments to adhere when brought into contact with the atmosphere.

Under the microscope cocoon silk presents the appearance of a somewhat flattened combination of two filaments placed side by side, being on an average $\frac{1}{1,200}$ in. in thickness. The cocoons are white or yellow in colour, oviform in shape, and often with a constriction in the middle. According to race, etc., they vary considerably in size and weight, but on an average they measure from an inch to an inch and a half in length, and from half an inch to an inch in diameter. They form hard, firm and compact shells with some straggling flossy filaments on the exterior, and the interior layers are so closely and densely agglutinated as to constitute a parchment-like mass which resists all attempts at unwinding. The whole cocoon with its enclosed pupa weighs from 15 grains for the smaller races to about 50 grains for the breeds which spin large cocoons. From 10 to 12 days after the completion of the cocoon the enclosed insect is ready to escape; it moistens one end of its self-made prison, thereby enabling itself to push aside the fibres and make an opening by which the perfect moth comes forth. The sexes almost immediately couple; the female in from four to six days lays her eggs, numbering 500 and upwards; and, with that the life cycle of the moth being complete, both sexes soon die.

SERICULTURE

The art of sericulture concerns itself with the rearing of silkworms under artificial or domesticated conditions, their feeding, the formation of cocoons, the securing of these before they are injured and pierced by the moths, and the maturing of a sufficient number of moths to supply eggs for the cultivation of the following year. The first essential is a stock of mulberry trees adequate to feed the worms in their larval stage. The leaves preferred in Europe are those of the white-fruited mulberry, *Morus alba*, but there are numerous other species which appear to be equally suitable. The soil in which the mulberry grows, and the age and condition of the trees, are important factors in the success of silkworm cultivation; and it has been too often proved that the mulberry will grow in situations where, from the nature of the leaf the trees put forth and from other circumstances, silkworms cannot be profitably reared. An elevated position with dry, friable, well-drained soil produces the best quality of leaves. Throughout the East the species of mulberry cultivated are numerous, but, as these trees have been grown for special purposes at least for three thousand years, they show the complex variations peculiar to most cultivated plants.

Incubation and Rearing of Worms.—The eggs of the silkworm, called "silk-seed" (Fr. *graines*), are hatched out at the period when the mulberry buds are breaking into leaf. The hatching is natural where the climate is uniformly hot, but in countries where the silkworm has been introduced, artificial heat has to be applied to the eggs. In many parts this is done by the primitive fashion of imparting to the seed the necessary heat by contact with the human body, but this gives an irregular and unduly protracted hatching. Simple incubators are now in use which make incubation regular, and the eggs all hatch out together, which is a great advantage from the point of view of economical feeding later on. The eggs are very minute—about 100 weighing a grain; and a vast number of hatched worms may at first be kept in a small space; but as the worms grow and require more and more leaves, the caterpillars require quickly increasing and ample space. The seed is distributed in perforated boxes to rearers, as it requires air all through the period of preservation until the worms are hatched. The boxes are opened and the seed is evenly spread on trays which are placed into the incubator; the lamp of the incubator is lit and the temperature is brought to 65° F. This is gradually increased daily by about 2° until it reaches 77°, at which temperature hatching takes place. The trays are withdrawn from the incubator and perforated paper or open-mesh gauze is spread over the minute worms; mulberry leaves, now young and very tender, are finely chopped and spread over the paper or gauze; the little worms wriggle up through the holes and begin feeding. The temperature of the room in which they are placed should be maintained at 77°. In more progressive countries, a special rearing house (Fr. *mag-*

PHOTOGRAPHS, KEYSTONE VIEW COMPANY

CULTURE OF SILKWORMS

1. Tray filled with thousands of worms of the silk producing type. Their eggs, called "silk seed," are hatched out at the period when the mulberry buds are breaking into leaf
2. Feeding mulberry leaves to silkworms. Leaves must be green but slightly wilted. During the final feeding, lasting about ten days, each worm consumes 20 times his own weight of the leaves
3. Silkworm cocoons in their nests. These nests consist of "brushes" of scrub oak or of some other many branched shrub placed vertically in the centre of the shelves where the worms have hitherto spent their lives. A worm indicates readiness to spin a cocoon by raising the forepart of the body and writhing slowly from side to side
4. Silkworm eggs being carefully placed in an incubator. An even heat is maintained starting at 65° F and raised 2° each day until 77° is reached at which temperature hatching takes place
5. Reeling the raw silk from the cocoon. Great care is taken not to break delicate thread
6. Weighing and sorting raw silk before it is sent away for spinning

nanerie) is allocated to the rearing of silkworms; it may be used for other purposes during the remainder of the year provided it is swept clean, disinfected and lime-washed ready for the reception of the worms. In more backward places, the dwelling of the peasant rearer is utilized, but the same scrupulous disinfection and cleanliness should be observed, though this is often neglected with unfortunate effects on the worms and the rearer. The place set apart for rearing should be well-ventilated, but not necessarily well lit, indeed, it should be capable of shading the worms from the direct rays of the sun, which are detrimental to them.

FIG. 2.—SILKWORMS SIX AND TEN DAYS OLD FEEDING ON A MULBERRY LEAF

Though there are many methods of keeping the worms during feeding, the best is probably to erect shelves about three feet wide in the centre of the room so that there is a walking space between them and the walls all round and gangways intersecting them. These shelves are constructed by means of light scantling from the floor to the ceiling with cross-pieces at intervals of two feet, the lowest being two feet above the floor. Over the frame-work thus created is laid large-mesh wire netting which, in this way, provides a series of shelves each two feet high. Paper is spread over the wire and the worms are placed on this; the worms increase in size with astonishing rapidity and they are given more and more space in conformity with their growth. No less remarkable is their growing voracity. After three or four days they are sufficiently grown to be able to consume whole young leaves, and from this time onwards their powers of consumption run parallel with the maturity of the mulberry. The feeding lasts about 42 days, but during that time the worm passes through four periods of sleep lasting 24 hours each; some races have only three periods of sleep, but these are rare. During this sleeping period the skin of the worm cracks and when the creature wakes up it is able to shed the old skin and continue with the new one. The importance of the regularity of hatching out now becomes apparent. The worms hatched out on the same day all sleep at the same time, and during the sleep do not require nourishment. If, however, the hatching out is irregular, sleeping and active hungry worms are mixed up, with the risk either of a waste of mulberry leaf or of malnutrition of the active worms. Worms will not touch faded leaves; the latter must be green but very slightly wilted. The sleeping periods occur on the sixth, twelfth, eighteenth and twenty-sixth day after hatching. After the fourth sleep, the worms start their great and final feed, lasting for ten days during which period they consume about twenty times their own weight of leaves.

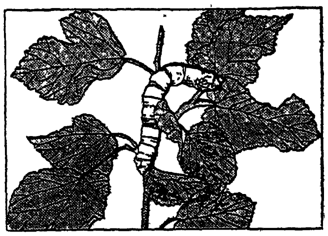
FIG. 3.—WORMS ABOUT 18 DAYS OLD

Laurent de l'Arbousset showed in 1905 that 1 oz. of seed of 30 grammes producing 30,000 to 35,000 silkworms (30,000 may be depended upon to reach the cocoon stage) will give a harvest of 130 to 140 lb. fresh cocoons and ultimate yield of about 12 lb. raw silk properly reeled. The amount of nourishment required for this rearing is as follows:—hatching to first moult, about 9 lb. of leaves of tender growth, equal to 40 to 45 lb. ripe leaves; first to second moult, 24 lb., representing 100 lb. ripe leaves; second to third moult, 80 lb., representing 240 lb. ripe leaves; third to fourth moult, 236 lb., representing 472 lb. ripe leaves; fourth moult to mounting, 1,430 lb., representing 1,540 lb. ripe leaves, totalling to about one ton of ripe leaves for a complete rearing. The growth of the worms during their larval stage is stated by Count Dandolo to be as follows: the small, black, newly hatched worm weighs about one-hundredth of a grain, and is about one-twelfth of an inch long; when it has reached its full growth, the large white worm weighs about ten grains, and is more than three inches long. Or, in tabular form:

	Weight per 100	Size in Lines
Worms newly hatched	1 gr.	1
After 1st moult	15 „	4
„ 2nd „	94 „	6
„ 3rd „	400 „	12
„ 4th „	1,628 „	20
Greatest weight and size	9,500 „	40

The Cocoons.—The worms show that they are ready to spin their cocoons by raising the forepart of the body and waving it slowly from side to side. Provision is now made for the structure on which they can spin. This consists of "bushes" of scrub-oak or other many-branched shrub which are placed vertically in the centre of the shelves on which the worms have hitherto spent their lives. Obedient to the dictates of nature, the worms, now replete with glutinous fibre, mount up into the bushes and proceed to spin the cocoons around themselves. If they are overcrowded there is the danger of two worms combining to spin one cocoon; this latter is practically useless for making silk as the combined threads are inextricably mixed up and the cocoon is incapable of being reeled into fine silk. After eight days, the bushes are removed from the shelves and the cocoons are picked off them. The importance of an even incubation is again demonstrated here, for if the hatch-out were irregular some worms would be ready to spin before others and the rearer would run the risk of taking down the bushes before all the worms had completed their spinning, resulting in some cocoons of inferior quality. On the other hand, the rearer dare not wait more than eight days, otherwise the chrysalis would complete its transformation and change into a moth which, in emerging from the cocoon, would cut through the silk fibres and destroy it for reeling purposes and thus render it practically valueless.

With the exception of those selected for reproduction of eggs, the cocoons are now treated so as to preserve them intact for reeling. The chrysalis must be killed without damage to the cocoon. The worm spins the cocoon with one continuous thread in a manner forming the figure 8, therefore the cutting of the cocoon at one end to allow the moth to escape means the cutting of the one continuous thread into many thousands of short ones and naturally makes it impossible to unwind ("reeling silk" is only another way of saying "unwinding cocoons"). The method adopted for killing the chrysalides—is that of suffocation. Leaving cocoons exposed to the hot sun will suffocate the chrysalides, but it also hardens the gum in the thread, making unwinding difficult and wasteful, and withdraws to a certain extent the colour from yellow cocoons. Another method is suffocation by steam. The cocoons are placed in shallow drawers in a cupboard which is constructed over a common washing copper. The bottoms of the drawers are constructed so as to allow of steam percolating through them. A fire is lit below the cauldron, which is filled with water, and steam is generated. The cocoons remain in the steam from eight to ten minutes and the chrysalis is suffocated. The cocoons are then spread lightly on canvas beds, sheltered from the sun, but where air can circulate freely. They remain on the beds from six weeks to two months, during which time they require to be turned over twice daily to prevent heating and the dead chrysalis gradually dries up without becoming putrid. In this method there is the risk of either keeping the cocoons in the steam too long and damaging the fibre, rendering the thread brittle, or not keeping them long enough so that the chrysalis, which has marvellous powers of recovery, will complete its metamorphosis and the moth will cut through after all. The safest and most practical method is suffocation by hot air. *Séchoirs*, or dryers, are constructed to take a large quantity of cocoons at one charge, and air is fanned through a steam-coiled chamber rendering it about 200° F. The hot air circulates by



BY COURTESY OF THE CORTICELLI SILK CO.

FIG. 4.—A SILKWORM, ALMOST FULL GROWN, FEEDING

means of channels through the chambers containing the cocoons, and the chrysalis is suffocated and all moisture in it dried up in one process of twelve hours' duration. The cocoons are put into sacks and stored without fear of deterioration. Exposure to air and wind, which also means exposure to dust and dirt, is unnecessary, and the colour of the silk when the cocoons are reeled is richer, while the water used in the reeling keeps clean.

Selection of Eggs for Reproduction.—The promiscuous production of eggs for the following crop by the rearers is strongly to be discouraged and in many countries it is absolutely prohibited, because of the great risk of propagating diseases to which the silkworm is prone. Reproduction, if a virile and healthy race of worm is to be preserved, must be under the supervision of experts. These experts choose rearers who are known to be extremely adept at cocoon-raising and give them specially selected eggs, each separate laying of which has been microscopically examined for the presence of disease. These eggs are known as "cellular seed." The experts pay periodical visits to the *magnanerie* during the rearing to examine the condition of the worms and take away any of doubtful appearance for microscopic examination. If the rearing is entirely successful and no trace of disease is found, the cocoons are taken to the "seed station," where they are examined. Ill-formed or imperfect cocoons are sent to be stifled and the selected ones are threaded together into long ropes and suspended from the ceiling to within a foot of the floor. In due course the moths emerge from the cocoons, mating takes place and the female is placed in a small linen bag, about 2 in. square, which has been washed and disinfected; the mouth is tied up and these bags are strung together and suspended from the ceiling of another room. The female lays its eggs in the bag and dies. The males, after two or three matings, are destroyed. This part of the process is carried on until the cocoon crop is at an end. The ratio of reproduction is about 250 to 1, so the seed stations require about 1,000 lb. of cocoons for seed for a crop of 25,000 lb. of cocoons the next season.

FIG. 5.—A SILKWORM MOTH EMERGING FROM ITS COCOON (FRONT VIEW)

As soon as the mating is over, work is begun on the microscoping of the seed which has been laid. In the case of selection for cellular seed, each bag is emptied of its contents, the seed is washed in water to free it from the remains of the dead female and a few seeds are crushed and placed on a slide for examination. If the microscope tells no tale of disease, that particular laying is passed. If traces of disease are found, the bag and its contents are burnt. In the case of seed not to be used for reproduction but only to be distributed for producing cocoons for silk, called industrial seed, each rearing is kept separate and the contents of all the bags of one rearing are emptied out together. This heap of seed is washed as before, is well mixed and half a dozen samples are taken, crushed and examined as before. If disease is detected, further samples are taken to determine the extent of it. If not more than 5% of disease is apparent, the rearing passes; if more, it is entirely destroyed. In this way all the eggs are gradually cleared through the microscoping room, a further washing takes place and, after the seed is dry, it is done up in small gauze bags in weights of 1 oz., ½ oz., and ¼ oz. These, in turn, are placed in perforated cardboard boxes and are ready for distribution to rearers the following season, the cellular seed being kept separate for selected rearers for a further cycle of reproduction.

FIG. 6.—SILKWORM MOTH EMERGING FROM ITS COCOON (SIDE VIEW)

The expert's task is not finished with the production of sound and healthy seed. He is also concerned with the cross-breeding of different varieties with a view to a higher yield of silk in the cocoons for reeling, to creating hardier races for different conditions of climate, to improving the cocoons of one part of the world by crossing the moths with those from another—an endless succession of problems for the propagation of sericulture in general.

DISEASES

That the silkworm is subject to many serious diseases is only to be expected of a creature which for upwards of 4,000 years has been propagated under purely artificial conditions, and these most frequently of a very insanitary nature, and where not the healthy life of the insect, but the amount of silk it could be made to yield, was the object of the cultivator. Among the most fatal and disastrous of these diseases with which the cultivator had long to grapple was "muscardine," a malady due to the development of a fungus, *Botrytis bassiana*, in the body of the caterpillar. The disease is peculiarly contagious and infectious, owing to the development of the fungus through the skin, whence spores are freed, which, coming in contact with healthy caterpillars, fasten on them and germinate inwards, giving off corpuscles within the body of the insect. Muscardine, however, has not been epidemic for many years.

The Pebrine Epidemic.—About the year 1853 anxious attention began to be given in France to the ravages of a disease among silkworms. This disease, which at a later period became known as *pebrine*—a name given to it by de Quatrefages, one of its many investigators—had first been noticed in France at Cavaillon in the valley of the Durance near Avignon. Pebrine manifests itself by dark spots in the skin of the larvae; the eggs do not hatch out, or hatch imperfectly; the worms are weak, stunted and unequal in growth, languid in movement, fastidious in feeding; many perish before coming to maturity; if they spin a cocoon it is soft and loose, and moths when developed are feeble and inactive. When sufficient vitality remains to produce a second generation it shows in increased intensity the feebleness of the preceding. The disease is thus hereditary, but in addition it is virulently infectious and contagious. From 1850 onwards French cultivators were compelled, in order to keep up their silk supply, to import graine from uninfected districts. The area of infection increased rapidly, and with that the demand for healthy graine correspondingly expanded, while the supply had to be drawn from increasingly remote and contracted regions. Partly supported by imported eggs, the production of silk in France was maintained, and in 1853 reached its maximum of 26,000,000 kilos of cocoons, valued at 117,000,000 francs. From that period, notwithstanding the importation at great cost of foreign graine, reaching in some years to 60,000 kilos, the production of silk fell off rapidly. In 1865 it touched its lowest weight of about 4,000,000 kilos. In 1867 de Quatrefages estimated the loss suffered by France in the 13 years following 1853, from decreased production of silk and price paid to foreign cultivators for graine, to be not less than one milliard of francs. In the case of Italy, where the disease showed itself later but even more disastrously, affecting a much more extended industry, the loss in 10 years de Quatrefages stated at two milliards. A loss of £120,000,000 sterling within 13 years, falling on a limited area, and on one class within these two countries, constituted indeed a calamity on a national scale, calling for national effort to contend with its devastating action. The malady, moreover, spread eastward, and, although it was found to be less fatal in Oriental countries than in Europe, the sources of healthy graine became fewer and fewer, till only Japan was left as an uninfected source of European graine supply.

A scourge which so seriously menaced the very existence of the silkworm in the world necessarily attracted a great amount of attention. As early as 1849 Guérin Méneville observed in the blood of diseased silkworms certain vibratory corpuscles, but neither did he nor the Italian Filippi, who studied them later, connect them distinctly with the disease. The corpuscles were first accurately described by Cornalia, whence they are spoken of as the corpuscles of Cornalia. The French Academy charged de Quatrefages, Decaisne and Péligot with the study of the disease, and they issued two elaborate reports—*Études sur les maladies actuelles des vers à soie* (1859) and *Nouvelles Recherches sur les maladies actuelles des vers à soie* (1860); but the suggestions

they were able to offer had not the effect of stopping the march of the disease. In 1865 Pasteur undertook a Government commission for the investigation of the malady. Attention had been previously directed to the corpuscles of Cornalia, and it had been found, not only that they occurred in the blood, but that they gorged the whole tissues of the insect, and their presence in the eggs themselves could be microscopically demonstrated. Pasteur established (1) that the corpuscles are the special characteristic of the disease, and that these invariably manifest themselves, if not in earlier stages, then in the mature moths; (2) that the corpuscles are parasites, and not only the sign but the cause of the disease; and (3) that the disease manifests itself by heredity, by contagion with diseased worms, and by the eating of leaves on which corpuscles are spread. In this connection he established the very important practical conclusion that worms which contract the disease during their own life-cycle retain sufficient vitality to feed, develop and spin their cocoon, although the next generation is invariably infected and shows the disease in its most virulent and fatal form. This fact, however, enabled the cultivator to know with assurance whether the worms on which he bestowed his labour would yield him a harvest of silk. He had only to examine the bodies of the moths yielding his graine: if they were free from disease then a crop was sure; if they were infected the education would assuredly fail.

Pasteur brought out the fact that the malady had existed from remote periods and in many unsuspected localities. He found corpuscles in Japanese cocoons and in many specimens which had been preserved for lengthened periods in public collections. Thus he came to the conclusion that the malady had been inherent in many successive generations of the silkworm, and that the epidemic condition was only an exaggeration of a normal state brought about by the method of cultivation and production of graine pursued. The cure proposed by Pasteur was simply to take care that the stock whence graine was obtained should be healthy, and the offspring would then be healthy also. Small educations reared apart from the ordinary magnanerie, for the production of graine alone, were recommended. At intervals of five days after spinning their cocoons specimens were to be opened and the chrysalides examined microscopically for corpuscles. Should none have appeared till towards the period of transformation and escape of the moths, the eggs subsequently hatched out might be depended on to yield a fair crop of silk; should the moths prove perfectly free from corpuscles after depositing their eggs the next generation would certainly live well through the larval stage. For special treatment towards the regeneration of an infected race, the most robust worms were to be selected, and the moths issuing from the cocoons were to be coupled in numbered cells, where the female was to be confined till she deposited her eggs. The bodies of both male and female were to be examined for corpuscles, and the eggs of those found absolutely free from taint were preserved for similar "cellular" treatment in the following year. By this laborious and painstaking method it has been found possible to re-establish a healthy stock of valuable races from previously highly-infected breeds. The rearing of worms in small educations under special supervision has been found to be a most effective means of combating pebrine. In the same way the rearing of worms for graine in the open air, and under natural conditions as far as possible, has proved equally valuable towards the development of a hardy, vigorous and untainted stock. The open-air education was originally proposed by Chavannes of Lausanne, and largely carried out in the canton of Vaud by Roland, who reared his worms on mulberry trees enclosed within "manchons" or cages of wire gauze and canvas. The insects appeared quickly to revert to natural conditions; the moths brought out in open air were strongly marked, lively and active, and eggs left on the trees stood the severity of the winter well, and hatched out successfully in the following season. Roland's experience demonstrated that not cold but heat is the agent which saps the constitution of the silkworm and makes it a ready prey to disease.

Other Diseases.—*Grasserie* is another form of disease incidental to the silkworm. It often appears before or after the first moult, but it is only after the fourth that it appears in a more developed form. The worm attacked presents the following symptoms: the skin is distended as if swollen, is rather thin and shiny, and the body of the worm seems to have increased, that is, it suffers from fatness, or is *engraissé*, hence its name. The disease is characterized by the decomposition of the blood; in fact it is really a form of dropsy. The blood loses its transparency and becomes milky, its volume increases so that the skin cannot hold it, and it escapes through the pores. This disease is more accidental than contagious and rarely takes very dangerous proportions. If the attack comes on a short time before maturity, the worms are able to spin a cocoon of a feeble character, but worms with this disease never change into chrysalides, but always die in the cocoon before transformation can take place. The causes which produce it are not well known, but it is generally attributable to currents of cold and damp air, to the use of wet leaves in feeding, and to sudden changes of temperature.

Another cause of serious loss to the rearers is occasioned by *flacherie*, a disease well known from the earliest times. Pasteur showed that the origin of the disease proceeded from microscopic organisms called ferments and vitrios. One has only to ferment a certain quantity of mulberry leaves, chop them up and squeeze them, and so obtain a liquid, to find in it millions of ferments and vitrios. It invariably occurs during the most active period of feeding, three or four days after the fourth moult up to the rising, and generally appears after a meal of coarse leaves, obtained from mulberries pruned the same year and growing in damp soil. It can also occur from the feeding of damp leaves, *e.g.*, leaves wetted by rain, to the worms or from leaves too freshly plucked and not allowed to wilt slightly. *Flacherie* is an intestinal disease of the cholera species and therefore contagious. The definite course is not occasioned so much from the ferments which exist in the leaves themselves, but from an arrest of the digestive process which allows the rapid multiplication of the former in the intestines. Good ventilation is indispensable to allow the worm to give out by transpiration the great quantity of water that it absorbs with the leaf. If this exhalation is stopped or lessened the digestion in its turn is also stopped, the leaf remains longer than usual in the intestines, the microbes multiply, invading the whole body, and this brings about sudden death. The true remedies consist in the avoidance of the fermentation of the leaves by careless gathering, transport or packing, in proper hygienic care in ventilation and in maintaining a proper degree of dryness in the atmosphere in rainy weather, and in the use of quicklime to facilitate the transpiration of the silkworms.

WILD SILKS

The ravages of pebrine and other diseases had the effect of attracting prominent attention to the numerous other insects, allies of the mulberry silkworm, which spin serviceable cocoons. It had been previously pointed out by Captain Hutton, who devoted great attention to the silk question as it affects the East Indies, that at least six species of *Bombyx*, differing from *B. mori*, but also mulberry-feeding, are more or less domesticated in India. These include *B. textor*, the boropooloo of Bengal, a large species having one generation yearly and producing a soft flossy cocoon; the Chinese monthly worm, *B. sinensis*, having several generations, and making a small cocoon; and the Madrasi worm of Bengal (*B. croesi*), the Dassee or Desi worm of Bengal (*B. fortunatus*) and *B. arracanensis*, the Burmese worm—all of which yield several generations in the year and form reelable cocoons. Besides these there are many other mulberry-feeding *Bombycidae* in the East, principally belonging to the genera *Theophila* and *Ocinara*, the cocoons of which have not attracted cultivators. The moths yielding wild silks which have obtained most attention belong to the extensive and handsome family *Saturnidae*. The most important of the species at the present time is the Chinese tussur or tasar worm, *Antheraea pernyi*, which is an oak-feeding species, native of Mongolia, from which is derived the greater part of the so-called tussur silk now imported into Europe. Closely allied to this is the Indian tussur moth, *Antheraea mylitta*, found throughout the whole of India feeding on the bher tree, *Zizyphus jujuba*, and also on many other plants. It yields a large compact cocoon of a silvery grey colour, which Sir Thomas Wardle of Leek, who

devoted a great amount of attention to the wild-silk question, succeeded in reeling. Next in promising qualities is the muga or moonga worm of Assam, *Antheraea assama,* a species to some extent domesticated in its native country.

The yama-mai worm of Japan, *Antheraea* (*Samia*) *yama-mai,* an oak-feeder, is a race of considerable importance in Japan, where it was said to be jealously guarded against foreigners. Its eggs were first sent to Europe by Duchêne du Bellecourt, French consul-general in Japan in 1861; but early in March following they hatched out, when no leaves on which the larvae would feed were to be found. In April a single worm got oak-buds, on which it throve, and ultimately spun a cocoon whence a female moth issued, from which Guérin Méneville named and described the species. A further supply of eggs was secretly obtained by a Dutch physician Pompe van Meedervoort in 1863, and, as it was now known that the worm was an oak-feeder, and would thrive on the leaves of European oaks, great results were anticipated from the cultivation of the yama-mai. These expectations, however, for various reasons, have been disappointed. The moths hatch out at a period when oak leaves are not ready for their feeding, and the silk is by no means of a quality to compare with that of the common mulberry worm. The mezankoorie moth of the Assamese, *Antheraea mezankooria,* yields a valuable cocoon, as does also the Atlas moth, *Attacus atlas,* which has an omnivorous larva found throughout India, Ceylon, Burmah, China and Java. The Cynthia moth, *Attacus cynthia,* is domesticated as a source of silk in certain provinces of China, where it feeds on the *Ailanthus glandulosa.* The eria or arrindi moth of Bengal and Assam, *Attacus ricini,* which feeds on the castor-oil plant, yields seven generations yearly, forming loose flossy orange-red and sometimes white cocoons. The ailanthus silkworm of Europe is a hybrid between *A. cynthia* and *A. ricini,* first obtained by Guérin Méneville, and now spread through many silk-growing regions. These are only a few of the moths from which silks of various usefulness can be produced; but none of these presents qualities, saving perhaps cheapness alone, which can put them in competition with common silk.

A wild silk which has entered the market since the beginning of the 20th century is Anaphe. It is found in West and East Africa. The worms combine to make large nests of cocoons with a strong outer protecting covering, tough as parchment. A peculiar and unpleasant quality of this species is the presence of hairs of a somewhat poisonous nature which bring out a rash on the skin when the nests are handled. Chemical treatment before handling has eliminated this trouble, but progress with the utilization of this silk is slow. It first began to attract attention in Germany in 1913 but its experimental stage was held up until 1920. At first, the outer cover was thrown away and the internal cocoons were treated, but it has since been found that the outer cover is the more valuable and the internal cocoons hardly worth the trouble of working. Natives use the nests for the manufacture of their blankets but its economic usefulness in Europe has still to be proved (1928). The systematic planting of the bush on which the Anaphe worm feeds would also be indicated if there is to be a constant and cheaper supply of this material.

PHYSICAL AND CHEMICAL PROPERTIES OF SILK

Common cocoons (*Bombyx mori*) enclosing chrysalides weigh each from 0·4 to 2 grams, *i.e.,* there are from 300 to 600 to the pound, for small breeds, and 270 to 300 for large breeds. About one-sixth of this weight is silk and of that one-half can be reeled, the remainder which cannot be reeled consisting of surface floss or blaze and the husk of the chrysalis. It is therefore difficult to estimate the total length of thread produced by the silkworm or even that of the portion reeled, which varies in length and thickness according to the condition and robustness of the cocoon and may be 500 metres in some breeds and in others 900 to 1,200 metres. Under favourable conditions 11 kilograms of fresh cocoons may give 1 kilogram of raw silk for commerce and about the same quantity of waste silk for spinning. The thread is usually thicker and stronger towards the middle of the reeled portion than at the extremities. The mean diameter of the cocoon thread or bave which is composed of two filaments of different specimens of mulberry silk was found at the Lyons laboratory to vary from 0·00180 to 0·0033 cm.; the bave of wild silks from 0·0030 to 0·0070 cm. The denier or weight in grams of 9,000 metres (*see* SILK MANUFACTURE) of the bave of mulberry silk varies from 1·8 to 3·8, and that of the bave of the Anthers (wild silks) from 3 to 8 deniers.

The raw silk fibre (*see* FIBRES) consists essentially of two cores of *fibroin* cemented together and covered with *sericin* or silk albumen, besides small quantities of waxy and colouring matters. The ultimate filaments of fibroin, which constitute about 70 to 80% of dry, raw mulberry silk have in bulk, after removal of the gum, the characteristic soft white appearance and pearly lustre of pure silk. Under the microscope the filaments appear smooth and rod-like and, when examined by polarized light, show the colours given by doubly refracting substances; their cross-section is roughly triangular (maximum diameter, 0·0023 to 0·0014 cm.; minimum diameter, 0·0018 to 0·0009 cm.). The filaments have great tensile strength (3 to 5×10^9 dynes per sq.cm.) extending considerably before breaking, and show true elastic effects under limited stresses (Young's modulus, 0·4 to $0{\cdot}8 \times 10^{11}$ and rigidity, $0{\cdot}2 \times 10^{11}$ dynes per sq.cm. under ordinary conditions). Their density is about 1·3, refractive index, 1·5 and specific heat, 0·3 calories per gram. The low electrical conductivity of fibroin, utilized in the employment of silk for electrical insulation, may cause a troublesome electrical excitation of the fibres during manufacturing processes in a dry atmosphere. Its thermal conductivity also is low. Under ordinary atmospheric conditions fibroin contains about 11% of its dry weight of hygroscopic moisture which may be removed by heating it at 105° C. It is insoluble but swells slightly in water, alcohol, benzene and other organic liquids.

Fibroin is an amphoteric colloid and belongs to the chemical class of proteins; the formula $C_{15}H_{23}N_5O_6$ sometimes assigned to it should be taken to be no more than an approximate expression of its elementary composition. The X-ray method of examination indicates the possible presence in fibroin of a crystalline constituent, and there is some chemical evidence that fibroin is chemically heterogenous. It dissolves in the cold in concentrated solutions of the mineral acids or of the caustic alkalies, and in an ammoniacal solution of copper oxide; from all these solutions it may be reprecipitated in a more or less altered form when the solution is neutralized, but, owing to more far-reaching changes, not after long standing. When heated, fibroin melts and burns giving a smell of burnt feathers which serves to distinguish it from the vegetable fibres, including artificial silk. It may be distinguished from wool by its microscopical appearance and by chemical tests. The ultimate filaments of the wild silks are thicker and more ribbon-shaped than those of mulberry silk and exhibit longitudinal striations along which the filaments tend to split into fibrillae under any mechanical or chemical action; the fibroin of the wild silks possesses properties similar to those of mulberry fibroin but is more resistant to chemical action. Sericin, also a protein, is more active chemically than fibroin, from which it may be separated by the solvent action of hot water, best under pressure, or of acid or alkaline solutions. Its hot aqueous solution gelatinizes on cooling. Its elementary composition is similar to that of fibroin but it contains more oxygen; like fibroin it may be chemically heterogenous. The colouring matter of yellow silk is probably *carotene* or a related substance.

Since 1916 a committee of experts has been sitting at the Imperial Institute to study the possibilities of sericulture in all parts of the Empire. Through its efforts the filature was erected in Cyprus, and it is following with practical advice the experimental work being carried on in a dozen other countries under the British flag. *See* SILK TRADE for a further study of the development of sericulture.

The U.S. Department of Agriculture, with appropriations made by Congress, conducted extensive experiments in sericulture. It was shown that cocoons of excellent quality can be produced in the many localities in the United States where the white mulberry tree grows well, but the conclusion reached by

the Department was that under the then existing economic conditions the raising of silk could not be made commercially successful.

SILK FABRICS, ARTIFICIAL. Except in the production of knitted and lace goods, as well as a small variety of woven luxury fabrics of the most delicate texture, artificial silk is of such a character that it may only be employed successfully when in combination with threads produced from the natural textile fibres, in order to constitute a foundation texture of sufficient stability according to the specific use for which the fabric is intended. It should be realized, therefore, that the special function of artificial silk (so far as the textile industry is concerned) is that of embellishing and enriching textile fabrics of any description that permit of decorative treatment.

Artificial silk may be employed in conjunction with cotton in any combination. Also, the warp and weft may be interwoven in order to develop any desired textural or woven effect from the simplest and most elementary weaves. Fabrics may also be produced either as simple or compound structures and decorated with simple figuring. Again, artificial silk threads either of the same colour or any number of different colours may be introduced in place of the ordinary warp and weft threads, or as extra threads of warp and weft, in order to produce simple or variegated stripes.

Special Precaution in Preparing Textile Designs.—In the development of brocade or "float" figuring with artificial silk, great care should be taken, when preparing an applied design for the card-cutter, to ensure thorough interlacement of the threads, and also to avoid floats of inordinate length. This precaution is especially necessary for fabrics that are subject to wear or friction, as, owing to the multi-filament structure of artificial silk threads, the fine filaments are easily caught up and broken. As a general rule, the decorative features of a woven fabric may be developed with much greater success with the warp than with the weft series of threads, for the practical reason that, during the operation of weaving, the warp threads are under much more complete control and tension than the weft. Consequently, the warp series of threads lie much straighter and firmer in the fabric, and thus produce a more perfectly flat and even surface than can be obtained by employing weft for figuring purposes. Moreover, not only does the greater tension of the warp threads tend to effect a better distribution of the fine filaments composing those threads, and thus ensure a more complete "covering" of the weft, but the additional tension (by keeping the threads straight) also increases their power of reflection, which enhances their lustre. Further, the employment of warp, instead of weft (whenever the choice of these alternatives is quite optional and solely for decorative effect, as distinct from technical and practical considerations) is a more economical policy from the manufacturers' point of view, besides incurring a smaller percentage of waste material.

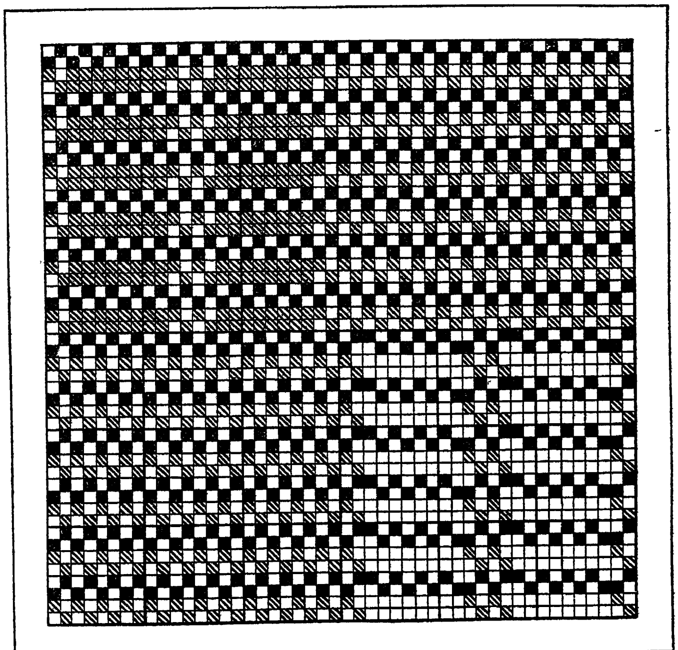

FIG. 1.—APPLIED DESIGN FOR CHENILLE VOILE FABRIC, A DRESS FABRIC CONSISTING OF A VOILE FOUNDATION INTERWOVEN WITH VELVET OR PLUSH PILE OF ARTIFICIAL SILK

The black squares indicate warp threads raised over picks of cotton weft, and the shaded squares, the warp raised over picks of artificial silk weft

Multi-colour Effects of Cross-Dyeing.—Another method of embellishing textile fabrics with artificial silk in combination with other textile materials is by what is known as "cross-dyeing," whereby two or more distinctly different hues and tones of colour may be produced in the same fabric by submitting it to a single dye-bath. This interesting phenomenon results entirely from the different chemical and physical properties of artificial silk and of the natural fibres. Hence, certain types of fibres react, on being submitted to the same dye-bath, in a manner quite different from that of other types, and thus assume different hues, according to the particular types of fibres employed, and their different affinity for dyestuffs.

Staple Artificial Silk Fibres.—Other uses to which artificial silk is applied in combination with cotton, wool and even natural silk, and one that offers ample scope in every section of the textile industry, is to cut the filaments of artificial silk into definite staple lengths and blend these with the fibres of cotton, wool or waste silk, respectively, to be spun together to produce "union" or "mixture" yarns.

Chenille Voile.—The various stages in the construction of this fabric is indicated by a portion of an applied or "working" design on point paper, in fig. 1, in which black squares indicate warp threads raised over picks of cotton weft, while the shaded squares show the warp raised over picks of artificial silk weft. After the cloth is woven, the ribs of floating artificial silk weft are "cut" up the centre in order to sever the floats of weft, which immediately assume a more or less vertical position, and thus constitute the tufts of cut velvet or plush pile, after the manner of forming the ribs of pile in corduroy and velvet cord fabrics (*see* FUSTIAN FABRICS). "Chenille voile" fabrics are sometimes woven with plain ribs or cords of pile, uniformly, and afterwards embellished with printed designs in one, or more than one, colour.

Embossed Plush Pile Fabrics.—The charming decorative qualities of artificial silk are displayed to their greatest perfection in so-called "embossed" plush or velvet pile figuring developed on a delicate texture of natural silk georgette and which was at one time very popular. This example is embellished with a design developed with a rich plush-pile figuring of artificial silk and subsequently printed with an effective colour scheme, displaying the artistic ability of the designer in conjunction with the handicraft skill of the weaver. The georgette foundation texture of this lovely dress material is produced from spun silk yarn with a high degree of twist, and with both the warp and weft threads twisted in "reverse" direction, *i.e.*, "twist-way" and "weft-way" respectively, in order to develop the peculiar, crimped tissue which is a distinctive characteristic of voile and georgette textures. The artificial silk pile figuring warp threads and the spun silk ground warp threads are drawn through the shedding harness and reed in pairs, with a "two-and-two" end disposition, uniformly. The ground warp threads of spun silk are disposed in the order of one thread spun with a "right-hand" twist (or "twist-way"), and one with a "left-hand" twist (or "weft-way"), in alternate succession, uniformly; while the ground picks of spun silk weft are inserted with three picks of weft spun "twist-way," and three spun "weft-way," uniformly.

Embossed plush pile fabrics of this character are produced in a "double-plush" loom of a special type in which two distinct fabrics are woven together simultaneously, face to face, with the figuring pile warp threads passing vertically between the upper and lower foundation textures which are severed automatically (whilst in the loom) during the operation of weaving. When not

required for figuring purposes, the figuring warp threads are floated quite loosely as surplus yarn on the back of their respective foundation fabrics, from which they are afterwards brushed away as waste material. This method of pile weaving necessitates the winding of the plush figuring warp threads on to separate flanged bobbins that are supported in a bobbin-creel frame, whereas the foundation warp threads are wound on to an ordinary warp beam.

See H. Nisbet, F.T.I., *Grammar of Textile Design* (3rd ed., 1927); a practical treatise on the principles of woven fabric structures, with a chapter on "The Decorative Value of Artificial Silk in Textile Fabrics." (H. N.)

SILK MANUFACTURE. In discussing silk manufacture, it is necessary to distinguish between reeled silk and spun or waste silk. The former embraces a range of operations peculiar to silk, dealing as they do with continuous fibres of great length, whereas in the spun silk industry the raw materials are treated by methods analogous to those followed in the treatment of other fibres (*see* WEAVING). It is only floss, injured and unreelable cocoons, the husks of reeled cocoons, and other waste from reeling, with certain wild silks, which are treated by spun silk process, and the silk thereby produced loses much of the beauty, strength and brilliance which are characteristic of the manufactures from reeled silk.

Filature or Reeling.—When the cocoons have been gathered and the chrysalids they contain have been stifled, they are sorted into qualities for reeling. Doubles (cocoons made by two worms in conjunction), pierced cocoons and any from other causes rendered unreelable are put aside for the spun silk manufacture. During the gathering from the rearers of "fresh" cocoons, *i.e.*, while the chrysalids are alive, a certain amount of crushing occurs, which smashes the chrysalis and naturally saturates the cocoon with its fluid. One cocoon thus crushed may be the cause of staining several others. Also, there are partly reelable cocoons made by unhealthy worms. A black fluid is exuded from some of these cocoons, which, in turn, stain all the cocoons in their vicinity. Worms which have been ill fed make cocoons of a weak thread. The sorting is done by hand, and the cocoons separated into four qualities, (*a*) cocoons which are perfectly clean and firm, (*b*) cocoons which are otherwise good but which have been stained by crushed cocoons, (*c*) weak cocoons, and (*d*) cocoons crushed and badly stained from within. The (*c*) and (*d*) qualities, which form but a small proportion of the whole, are reeled as quickly as possible, for they are liable, if kept in store, to attack from an insect fly which bores a minute hole about the size of a pinhead through them and renders them unsuitable for reeling. The (*b*) quality, which forms about 20% of the whole, is also susceptible to the insect, but to a much smaller degree, so these are worked next, leaving the (*a*) quality for the remainder of the year's work. This assortment is of great consequence for the success of the reeling operations, as uniformity of quality and evenness and regularity of fibre are the most valuable features in raw silk. The object of reeling is to bring together the filaments (Fr. *bave*) from two or more (generally five or six, but sometimes up to 20) cocoons, and to form them into one continuous, uniform and regular strand, which constitutes the "raw silk" of commerce. To do this, the natural gum of the cocoons which holds the filaments together must be softened, the ends of the filaments must be caught, and means must be taken to unwind and lay these filaments together, so as to form a simple uniform rounded strand of raw silk. This reeling process is generally carried out by female labour; it is extremely delicate but by no means hard work. The establishment in which it is done is called a filature, and may consist of anything from 20 to 300 reeling basins. Each reeler is issued with a given weight of cocoons, and the worker who prepares them for the reeler places a quantity of them in a round deep basin with water kept at a certain level automatically and heated to boiling point by a steam coil in the bottom. A circular bass broom made to fit exactly over the basin is shut down on the soaking cocoons (which float on the surface of the water) so that the ends of the bass just touch the tops of the cocoons. The broom is set to work in a circular motion first one way and then the other by machinery until the ends of the broom have caught the outside fluff and the actual filament (*maître brin*) is found. The worker pulls up the broom, disengages the hank of fluff from the bass from which now depends the filament of each cocoon separately. She catches up the cocoons from the water by means of a strainer and passes it over to the reeler. The latter empties the cocoons into her basin, which also contains water kept at a level automatically and heated by a steam coil to 180° to 200° F. She then "makes her threads."

Filatures are constructed to enable four, six and eight skeins to be reeled by one reeler at a time. The reeler takes the filaments of, say, six cocoons and makes one thread of them by twisting them together; this combined thread is passed through an apparatus about 2 in. above the water level, upwards about 18 in. round a tiny glass conducting reel, then downwards round a similar glass reel and upwards again until the thread crosses itself. Here it is twisted round itself many times and is then taken through a glass conducting hook above the reeler's head, passed through a porcelain slit and finally attached to the reel on which the skein is to be wound. The process is repeated until the four, six or eight threads, each consisting of the threads of six cocoons, are attached to the reels. The reels are set revolving by means of a control lever ready at the reeler's hand, and as the reels revolve, they pull the threads; if eight skeins are being reeled, the 48 cocoons which go to make the eight threads all begin to turn about in the water as they unwind themselves in response to the pulling of the reels. When each thread is in motion, it travels through the apparatus with a minute hole, which prevents to a great extent any imperfection in the thread getting through, then through the twist on itself, then round the two glass conducting reels, then through the twist on itself for the second time and thence to the porcelain slit just in front of the reel, and finally on to the reel itself. The porcelain slit has a short cross motion of about 1½ in. which spreads the skein evenly over the surface of the reel. The twist on itself given to the thread is most important for it performs two functions; it rounds, smooths and condenses the six separate filaments into one strand, and as the surface of the filaments is gummy and adhesive, the threads are agglutinated into a compact single fibre of raw silk. The twist also expels from the thread all the moisture on it from the water in the basin in the form of spray and it reaches the reel practically dry. A silk thread made up of the filaments of six cocoons is scarcely visible, and yet it can easily stand the strain imposed on it by this twist on itself which is as long as six inches. A good silk should stretch about one-third of its own length before reaching breaking point. During the reeling process, the cocoons, of course, give off all their silk in a short time and breaks continually occur, so the reeler has to watch the unwinding cocoons carefully and directly she detects a cocoon that is motionless, she supplies the thread of another from a reserve which she keeps ready. The apparatus through which the thread is originally passed has a little disc attached to it which revolves rapidly. The reeler places the filament of the new cocoon across her extended first and second fingers, she advances her fingers to the disc, one above and one below, the disc cuts the filament and whirls it round the others which absorb it, and the new cocoon begins unwinding. A break of one filament in a thread of six will be rectified by a first-class reeler before half a yard of thread has gone through. All cocoons whose filaments break before they are finished are returned to have their filaments found again by a second brushing.

As soon as the cocoons issued to the reeler are finished, the silk is removed from the reels and taken to the silk room. It is weighed and a ratio to the quantity of cocoons used is found. The value of silk permits of no unnecessary waste and this control is important. The skeins are then examined for any defects. These consist of small knobs on the thread like pinheads, or a very coarse piece 3 or 4 in. long due to a cocoon not unwinding evenly. The knobs are picked off, the coarse pieces removed and clean thread is inserted in their place. The skeins are twisted up and packed into a bale.

Silk Waste.—The outer covering or fluff which is brushed off the cocoons in finding the filaments is a valuable waste used by silk spinners. Its trade name is knubs (Fr. *frisons*). A thin film of silk is left round the chrysalis when reeling is completed. The chrysalids with this film are boiled up in a vat and stirred with beaters which tear the film off. This is a low grade waste also used by spinners. The chrysalids are dried and form a valuable manure. Thus nothing is lost.

Throwing.—Raw silk, being still too fine and delicate for ordinary use, next undergoes a series of operations called throwing, the object of which is to twist and double it into more substantial yarn. The first operation of the silk throwster is winding. He receives the raw silk in hanks as it is taken from the reel of the filature, and putting it on a light reel of a similar construction, called the swifts, he winds it on bobbins with a rapid reciprocating motion, so as to lay the fibre in diagonal lines. These bobbins are then in general taken to the first spinning frame, and there the single strands receive their first twist, which rounds them, and prevents the compound fibre from splitting up and separating when, by the subsequent scouring operations, the gum is removed which presently binds them into one. Next follows the operation of cleaning, in which the silk is simply reeled from one bobbin to another, but on its way it passes through a slit which is sufficiently wide to pass the filament but stops the motion when a thick lump or nib is presented. In the doubling, which is the next process, two or more filaments are wound together side by side on the same reel, preparatory to their being twisted or thrown into one yarn. Bobbins to the number of strands which are to be twisted into one are mounted in a creel on the doubling frame, and the strands are passed over smooth rods of glass or metal through a reciprocating guide to the bobbin on which they are wound. Each separate strand passes through the eye of a faller, which, should the fibre break, falls down and instantly stops the machine, thus effectually calling attention to the fact that a thread has failed. The spinning or throwing which follows is done on a frame with upright spindles and flyers, the yarn as it is twisted being drawn forward through guides and wound on revolving bobbins with a reciprocating motion. From these bobbins the silk is reeled into hanks of definite length for the market. Numerous attempts have been made to simplify the silk-throwing by combining two or more operations on one machine, but not as yet with much success.

According to the qualities of raw silk used and the throwing operations undergone the principal classes of thrown silk are—(1) "singles," which consist of a single strand of twisted raw silk made up of the filaments of eight to ten cocoons; (2) tram or weft thread, consisting of two or three strands of raw silk not twisted before doubling and only lightly spun (this is soft, flossy and comparatively weak); (3) organzine, the thread used for warps, made from two and rarely three twisted strands spun in the direction contrary to that in which they are separately twisted. Silks for sewing and embroidery belong to a different class from those intended for weaving, and thread-makers throw their raw silks in a manner peculiar to themselves.

Numbering of Silk.—Silk is graded for thickness of thread like cotton, but instead of the size being termed "counts" it is measured in "deniers." The French denier weighs one-twentieth part of a gramme. The basis for raw and thrown silk adopted by the permanent committee of the Paris international congress of 1900 was a fixed length and a variable weight, the standard of length being 450 metres and the weight the "denier." Thus, a manufacturer gives an order for a bale of silk of 13–15 deniers. By this is meant that a thread is required of which 450 metres measured off will weigh between 13 and 15 deniers. Silk is reeled as fine as 8–10 deniers and as coarse as 28–30 deniers—for some purposes even 38–40 deniers. A silk cocoon has a filament of three deniers in its early stages of unwinding, two and a half deniers in the middle and two deniers at the end, so in order to arrive at a size of 13–15 deniers it is required to reel a thread of two new, two half-reeled and two nearly finished cocoons. During the reeling tests are carried out to see that the size is properly maintained. A reel is taken away from the reeler and carried to the testing room, where a winding machine measures off 450 metres from the reeled silk. This silk is put on the balances and if it weighs 14 deniers it is perfect, if 13 or 15 deniers it is good, if 12 or 16 deniers it is passable, but if it weighs 11 or 17 deniers it is bad and the reeler has been reeling a thread with less or more than the six cocoons combined.

Conditioning.—Silk in the ordinary dry condition usually contains about 10 per cent of hygroscopic moisture, the exact amount depending on the relative humidity of the atmosphere with which it is in contact. As it is largely sold by weight it becomes necessary to ascertain its condition in respect of absorbed water, and for that purpose official conditioning houses are established in all the considerable centres of silk trade. In these the silk is tested or conditioned, and a certificate of weight issued in accordance with the results. The silk is for four hours exposed to a dry heat of 230° F, and immediately thereafter weighed. To the weight 11% is added as the normal proportion of water held by the fibre.

Scouring.—Up to this point the silk fibre continues to be comparatively lustreless, stiff and harsh from the coating of albuminous matter (gum or *grès*) on its surface. As a preliminary to many subsequent processes it is therefore necessary to remove the gum by boiling off, scouring or *décreusage*. Silk is usually boiled-off in a solution of 30 per cent of its own weight of neutral soap dissolved in sufficient pure water to give a one per cent solution. The hanks of raw silk hung on a wooden rod are immersed in this solution which is maintained at a temperature just below the boiling point, the hanks being turned round to expose all parts equally to the solvent action of the hot solution. After one hour the silk is removed, centrifuged, then treated similarly in a second bath with half the quantity of soap. It is finally rinsed and dried in a hydro-extractor. According to the amount of gum to be boiled off the soap solutions are made strong or weak; but care has to be exercised not to overdo the scouring, whereby loss of strength, substance and lustre would result. The perfect scouring of silks removes from 20 to 27 per cent of their weight, according to the character of the silk and the amount of soap or oil used in the working. Scouring renders all common silks, whether white or yellow in the raw, a brilliant pearly white, with a delicate soft flossy texture, from the fact that the fibres which were agglutinated in reeling, being now degummed, are separated from each other and show their individual tenuity in the yarn. Silks to be finished white are at this point bleached by exposure in a closed chamber to the fumes of sulphurous acid, and at the close of the process the hanks are washed in pure cold water to remove all traces of the acid. Instead of "sulphuring" a dilute solution of hydrogen peroxide containing sodium silicate may be used for bleaching. Much thrown silk is woven or knitted without having been boiled-off, the gum being then usually removed from the woven or knitted fabric (piece-degumming).

Weighting.—The weighting of silk, which is by no means universal, and which when practised is confined usually to certain classes of goods, is facilitated by the ease with which silk absorbs various metallic salts and organic substances.

In tin weighting, the silk yarn or cloth, usually degummed, is soaked in an aqueous solution of stannic chloride and then washed exhaustively with water when hydrated stannic oxide is precipitated in the fibre; if the weighted silk is now soaked in a solution of sodium phosphate the stannic oxide present in the fibre is rendered insoluble in the solution of stannic chloride and so, with each repetition of the same series of operations, a further quantity of stannic oxide is fixed by the silk which may be treated finally with a solution of sodium silicate. The compounds of tin are fixed permanently in the fibre, unless against chemical treatment, and the weighted silk may be washed or dyed like unweighted silk from which it differs little in outward appearance. The mineral matter, besides adding weight, makes the fibres somewhat thicker, thus increasing their covering power and allowing cheaper goods to be made of weighted than of unweighted silk; on that account and because weighted silk garments drape well, the practice is held by many to be justified. By the removal of the gum,

raw silk loses about one quarter of its weight; if the original weight is restored by the addition of mineral matter to the degummed silk, the silk is said to be weighted "to par"; heavier weightings are described as so much per cent "above par." The weighting does not usually exceed 50% above par. The strength of the fibre remains unimpaired after weighting but weighted silk is more sensitive to the action of light than unweighted silk.

In black weighting the silk is treated with salts of iron and logwood or tannins such as extracts of sumac, divi-divi, chestnut, catechu from the Areca or Acacia and gambier from the Uncaria. The silk is frequently "bottomed" with Prussian blue or tin weighted, before being black weighted with various combinations of the above materials. Black weighted silk is highly resistant to the deteriorating action of sunlight.

Dyeing.—Silk may be dyed with acid, basic or direct cotton colours or with vat or mordant dyes; but acid dyes are still the most commonly used. The application to silk of vat dyes which are necessary for many very fast shades requires special care because of the sensitiveness of the fibre to the alkaline solutions which must be used with these dyes.

Although tussur and other silks from wild moths are readily dyed, the dyeing is apt to be uneven; and as these wild silks are usually of a fawn or brown colour which is not readily bleached it is difficult to dye them successfully with light or brilliant colours. Pioneers in this field were Sir Thomas Wardle and Tessié du Motay who made use of potassium permanganate to bleach the fawn colour of tussur; this reagent tends, however, to destroy the fibre itself and gentler means of oxidation, such as, a dilute solution of hydrogen peroxide made slightly alkaline with sodium silicate, are now employed to bleach tussur to a fairly pale ground.

THE SPINNING OF "SILK WASTE"

The term *silk waste* includes all kinds of raw silk which may be unwindable, and therefore unsuited to the throwing process. Before the introduction of machinery applicable to the spinning of silk waste, the refuse from cocoon reeling, and also from silk winding, which is now used in producing spun silk fabrics, hosiery, etc., was nearly all destroyed as being useless, with the exception of that which could be hand-combed and spun by means of the distaff and spinning wheel, a method which is still practised by some of the peasantry in India and other Eastern countries.

The supply of waste silk is drawn from the following sources: (1) The silkworm, when commencing to spin, emits a lustreless and uneven thread with which it suspends itself from the twigs and leaves of the tree upon which it has been feeding, or from straws provided for it by attendants in the worm-rearing establishments: this first thread is unreelable, and, moreover, is often mixed with straw, leaves and twigs. (2) The outside layers of the true cocoon are too coarse and uneven for reeling; and as the worm completes its task of spinning, the thread becomes finer and weaker, so both the extreme outside and inside layers are put aside as waste. (3) Pierced cocoons—*i.e.*, those from which the moth of the silkworm has emerged—and damaged cocoons. (4) During the process of reeling from the cocoon the silk often breaks; and both in finding a true and reelable thread, and in joining the ends, there is unavoidable waste. (5) Raw silk skeins are often re-reeled; and in this process part has to be discarded: this being known to the trade as gum-waste. The same term—gum-waste—is applied to "waste" made in the various processes of silk throwing; but manufacturers using threads known technically as organzines and trams call the surplus "manufacturer's waste." Finally we have the uncultivated varieties of silks known as "wild silks," the chief of which is tussur. The different qualities of "waste," of which there are many, vary in colour from a rich yellow to a creamy white; the chief producing countries being China, Japan, India, Italy, France and the countries in the Near East; and the best-known qualities are: steam wastes, from Canton; knubs, from China and from Italy and other Western countries; frisons, from various sources; wadding and blaze, Shanghai; China, Hangchow, and Nankin buttons; Indian and Szechuen wastes; punjum, the most lustrous of wastes; China curlies; Japan wastes, known by such terms as kikai, ostue, etc.; French, Swiss, Italian, China, Piedmont, Milan, etc. There are yellow wastes from Italy, and many more far too numerous to mention.

A silk "throwster" receives his silk in skein form, the thread of which consists of a number of silk fibres wound together to make a certain diameter, the separate fibres having actually been spun by the worm, and this fibre may measure anything from 500 to 1,000 yd. in length. The silk-waste spinner receives his silk in quite a different form: merely the raw material, packed in bales of various sizes and weights, the contents being a much-tangled mass of all lengths of fibre mixed with much foreign matter, such as ends of straws, twigs, leaves, worms and chrysalids. It is the spinner's business to straighten out these fibres, with the aid of machinery, and then to so join them that they become a thread, which is known as spun silk.

There are two distinct kinds of spun silk—one called "schappe" and the other "spun silk" or "discharged spun silk." All silk produced by the worm is composed of two substances—fibroin, the true thread, and sericin, which is a hard, gummy coating of the "fibroin." Before the silk can be manipulated by machinery to any advantage, the gum coating must be removed, really dissolved and washed away—and according to the method used in achieving this operation the result is either a "schappe" or a "discharged yarn." The former, "schapping," is the French, Italian and Swiss method, from which the silk when finished is neither so bright nor so good in colour as the "discharged silk"; but it is very clean and level, and for some purposes absolutely essential, as, for instance, in velvet manufacture.

Schapping.—The method is as follows: If waste silk is piled in a heap in a damp, warm place, and kept moist and warm, the gum will in a few days' time begin to ferment and loosen, and can then be washed off, leaving the true thread soft and supple; but the smell caused by the fermentation is so offensive that it cannot be practised in or near towns. Therefore schappe spinners place their degumming plant in the hills, near or on a stream of pure water. The waste silk is put into large kilns and covered with hot water (temperature 170° F). These are then hermetically closed, and left for a few hours for the gum to ferment and loosen. When thoroughly softened—the time occupied depending on the heat of the water and nature of the silk—the contents of the kiln are taken out and placed into vats of hot water, and allowed to soak there for some time. Thence the silk is taken to a washing machine, and the loosened gum thoroughly washed away. The silk is then partly dried in a hydro-extractor, and afterwards put in rooms heated by steam-pipes, where the drying is completed.

"Discharging" is the method generally used by the English, and results in a silk having brilliance and purity of colour. In this process the silk waste is put into strong, open-meshed cotton bags, made to hold (in accordance with the wish of individual spinners) from 1 lb. to 5 lb. in weight. When about 100 lb. of silk has been bagged, the whole is placed in a large wooden tub and covered with boiling water in which 12 to 20 lb. of white curd soap has previously been dissolved. In this the silk is boiled from one to two hours, then taken out and put through a hydro-extractor to remove the dirty gummy solution. Afterwards it is put into another tub of soapy liquor, and boiled from one to one and a half hours. It is then once more hydro-extracted, and finally taken to a stove and dried. "Discharged silk" must be *entirely free* from gum when finished, whereas "schappe" contains a percentage of gum—sometimes as much as 20%.

From this stage both classes of silk receive much the same treatment, differing widely in detail in different mills and districts.

The "degummed silk," after it is dried, is allowed to absorb a certain amount of moisture, and thus it becomes soft and pliable to the touch, and properly conditioned for working by machinery.

When the waste contains any large percentage of worm or chrysalis, it is taken to a "cocoon beater," a machine which has a large revolving disk on which the silk is put, and while revolving slowly is beaten by a leather whip or flail, which loosens the silk and knocks out the wormy matter. After the beating, the silk presents a more loose appearance, but is still tangled and mixed in length of fibre. The object of the spinner at this point is to

SILK MANUFACTURING MACHINERY

1. Winding silk on bobbins, rapid reciprocating motion used to lay fibre in diagonal lines
2. Throwing or spinning the silk. Frame pictured has upright spindles and flyers. As yarn is twisted it also is drawn forward through guides and wound on revolving bobbins. From the bobbins silk is reeled into hanks of definite length for the market
3. Weaving silk Sebastian brocade on Jacquard loom, woven pattern in material determined and controlled by Jacquard cards hanging from above
4. Modern power loom with motion conveyed to all working parts from a main shaft. Healds control all warps in plain or printed goods

straighten out the tangles and lumps, and to lay the fibres parallel: the first machine to assist in this process being known as an opening machine, and the second as a filling engine.

Opening and Filling.—The silk to be opened is placed on a latticed sheet or feeder, and thus slowly conveyed to a series of rollers or porcupines (rollers set with rows of projecting steel pins), which hold the silk firmly while presenting it to the action of a large receiving drum, covered with a sheet of vulcanized rubber, set all over with fine steel teeth. As the drum revolves at a good speed, the silk is drawn by the steel teeth through the porcupines into the drum in more or less straight and parallel fibres. When the teeth are full the machine is stopped, and the silk stripped off the drum, then presenting a sheet-like appearance technically known as a "lap." The lap is taken to the filling engine, which is similar in construction and appearance to the opener as far as the feeding arrangements are concerned, but the drum, in place of being entirely covered with fine steel teeth, is spaced at intervals of from 5 to 10 in. with rows of coarser straight teeth, each row set parallel with the axle of the machine. The silk drawn by the rows of teeth on the drum through the porcupine rollers (or porcupine sheets in some cases) covers the whole of the drum, hooked at certain intervals round the teeth; and when a sufficient weight is on the machine, it is stopped, and an attendant cuts, with a knife, the silk along the back of each row of teeth, thus leaving a fringe of silk hooked on the pins or teeth. This fringe of silk is placed by the attendant between two hinged boards, and whilst held firmly in these boards (called book-boards) is pulled off the machine, and is called a "strip"; the part which has been hooked round the teeth is called the "face," and the other portion the "tail." By these means the silk has been opened, straightened and then cut into a certain length, the fibres now being fairly laid parallel and ready for the next operation, known as silk dressing.

Silk Dressing.—This is the process equivalent to combing in the wool industry. Its purpose is to sort out the different lengths of fibre, and to clear such fibres of their nibs and noils. There are two well-known principles of dressing: one known as "flat frame," giving good results with discharged silk, and the other known as "circular frame" dressing, suitable for schappes.

The flat dressing frame is a box or frame holding a certain number of book-boards from the filling engine, which boards when full of silk are screwed tightly together in the frame. The frame is capable of being raised into contact with travelling combs, affixed to an endless belt placed round two metal rollers about 6 ft. apart. The attendant allows the silk to enter gradually into close contact with the combs, which comb through the silk in exactly the same manner as a lady combs her tresses. In a circular frame the silk is clamped between boards, and these are fixed on a large drum. This drum revolves slowly, and in its revolution conveys the fringes of silk past two quickly running smaller combing drums. These combing drums being covered with fine steel teeth penetrate their combs through the fringes of silk depending from the large drum, thus combing through the silk. In each machine the object is the same. First the filled silk is placed into a holding receptacle, clamped fast, and presented to combing teeth. These teeth retain a certain proportion of shorter fibre and rough places and tangled portions of silk, which are taken off the combs in a book-board or wrapped round a stick and again presented to the combs. This fibre again yields combings which will also be combed, and so on for five or six times until the combings are too short, and are taken from the machine and known as "noils." The productions from these several combings are known as "drafts" and are of different lengths: the product of the filled silk first placed in the dressing frame being the longest fibre and of course the most valuable.

The flat frame is the most gentle in its usage of the silk, but is most costly in labour; whilst the circular frame, being more severe in its action, is not suitable for the thoroughly degummed silks, but on the other hand is best for silks containing much wormy matter, because the silk hanging down into the combing teeth is thoroughly cleansed of such foreign matter, which is deposited under the machine. This method also has the advantage of being cheaper in cost of labour. Recently a machine has been invented giving the same results as the circular frame: the silk descends from boxes into combs, and at the same time has the gentle action of the flat frame. The cost of the operations is as cheap as the circular frame, therefore the machine combines the advantages of each of its predecessors.

Noils.—The noils resulting from the dressing operations are sometimes combed, the comb used being similar to those used in the cotton trade. The resulting sliver is used by silk spinners who make a speciality of spinning short fibres, and the exhaust noils are bought by those who spin them up into "noil yarns" on the same principle as wool. The yarns are chiefly used by manufacturers of powder bags. The noils are also in great demand for mixing with wool to make fancy effects in wool cloths for the dress goods trade.

Drafts.—The drafts from the dressing frame are valued in accordance with their length of fibre, the longest being known as A or 1st drafts and so on:—

	1st drafts	2nd drafts	3rd drafts	4th drafts	5th drafts	6th drafts
or as quality	A	B	C	D	Shorts	

Each draft may be worked into a quality of its own, and by such means the most level yarns are obtained. But occasionally one or more drafts are mixed together, when price is the determining factor.

Processes Peculiar to Silk Spinning Industry.—The foregoing processes are all peculiar to the silk waste trade, no other fibre having to go through such processes, nor needing such machinery. In the first stages of the spun-silk industry, the silk was dressed before boiling the gum out; the resulting drafts were cut into lengths of one or two inches. The silk was then boiled and afterwards beaten, scutched, carded, drawn, spun, folded, etc., in exactly the same way as fine cotton. Short fibre silks are still put through cards and treated like cotton; but the value of silk is in its lustre, elasticity and strength, which characteristics are obtained by keeping fibres as long as possible. Therefore, when gill drawing machinery was invented, the cutting of silk into short fibres ceased, and long silks are now prepared for spinning in what is known as "long spinning process." Following the process of dressing, the drafts have to go through a series of machines known as preparing machines: the object being to piece up the lengths of fibre, and to prepare the silk for spinning.

Preparing or Drawing Machinery.—A faller or gill drawing machine consists of a long feeding sheet which conveys silk to a pair of rollers (back rollers). These rollers present the silk to a set of fallers (steel bars into which are fixed fine steel pins), which carry forward the silk to another pair of rollers, which draw the silk through the pins of the fallers and present it to the rollers in a continuous way, thus forming a ribbon of silk called a "sliver." The fallers are travelled forwards by means of screws, and when at the end of the screw are dropped automatically into the thread of a receiving screw fixed below, which carries the fallers back to their starting point to be raised by cams into the top pair of screws thus to repeat their journey.

Silk Spreader.—This is the first of the series of drawing machines. The drafts from the dressing frame are made into little parcels of a few ounces in weight, and given to the spreader, who opens out the silk and spreads it thinly and evenly on to the feeding sheet, placing a small portion of the silk only on the sheet. Another portion is opened out and placed tail end to the first portion; and these operations are repeated until the requisite weight is spread. During this time the silk has been conveyed through the fallers and into a large receiving drum about 3 ft. in diameter, the silk being wrapped thinly and evenly all round the circumference of the drum. When the agreed-on weight is on the drum, the silk is drawn across the face of the drum parallel with its axle, and pulled off in form of a sheet, and is called a lap. This lap is thin, but presents the fibres of silk now joined and overlapped in a continuous form, the length measured by the circumference of the drum. This lap is sometimes re-spread to make it more even, and at other times taken

to a drawing machine which delivers in a sliver form. This sliver is taken through a series of four other drawing machines called "four head drawing box." Eight or more slivers are put behind the first drawing head, conveyed through the fallers and made into one sliver in front of the machine. This sliver is put up behind the second drawing; eight or more ends together run through the second head again into one sliver; and so on through the third and fourth heads of drawing. All these doublings of the sliver and re-drawing are for the purpose of getting each fibre to lie parallel and to make the sliver of an equal weight over every yard of its length. From the last head of drawing the sliver is taken to a machine known as a gill rover. This is a drawing machine fitted with fallers through which the sliver is drawn, but the end from the front roller is wound on to a bobbin. The machine is fitted with 20 to 40 of these bobbins placed side by side, and its product is known as "slubbing roving," it being now a soft, thick thread of silk, measuring usually either 840 or 1,260 yd. to 1 lb. weight. Hitherto all the drawing has been by rollers and fallers, but in the next machine the drawing is done by rollers only.

Dandy Roving Frame.—This is a frame built with forty or more spindles. Two or three slubbing rovings are put up behind the machine opposite each spindle; each end is guided separately into back rollers and thence between smaller rollers, known as carrier rollers, to the front rollers. The back rollers revolve slowly, the front rollers quickly, thus drawing the rovings out into a thinner size or count. The product is wound on to the bobbin by means of flyer and spindle, and is known as dandied or fine roving, and is then ready for the spinning frame.

Spinning.—The spinning is done by exactly the same methods as cotton or worsted, viz., either mules, ring frames, cap or flyer frames, the choice of machine being determined by the size or count of yarn intended to be produced.

Twisting and Doubling.—If a 2-fold or 3-fold yarn is needed, then two or more ends of the spun thread are wound together and afterwards conveyed to the twisting frame for the purpose of putting the needed twist in the yarn necessary for weaving or other requirements. This process is exactly the same as in the cotton or worsted industry, ring or flyer frames being used as desired.

Weft Yarns.—These are taken straight from the spinning frame, wound on to a long paper tube and so delivered to the manufacturer ready to place in the loom shuttle.

Folded Yarns are hairy after being spun and folded, and in addition sometimes contain nibs and rough places. The fibre and nibs have to be cleaned off by means of a gassing machine so constructed that the end of silk (silk yarn) is frictioned to throw off the nibs, and at the same time is run very rapidly through a gas flame a sufficient number of times to burn off the hairy and fibrous matter without injuring the main thread. The yarn is now ready for reeling into skeins or for warping, both of which operations are common to all the textile yarns. It may be washed or dyed just as required, either in hank or in warp.

Growth of Industry and Uses of Spun Silk.—As will have been gathered, spun silk is pure silk just as much as that used by the throwster. The spinning industry has not decreased in England. The number of mills has decreased, but machinery now runs so much more quickly than formerly that more yarn is being spun on fewer spindles. The American spinning industry has more than doubled its output since 1914 under a protective tariff of some 35%. The Continental spinners have increased, but are developing into huge syndicates, all working on the schappe principle. The three chief syndicates, one each in Italy, France and Switzerland, work very much together, practically ruling the prices for yarns and raw materials.

Spun silks are used largely for silk linings, hosieries, sewing threads, elastic webbing, lace, plush and many other purposes, such as mufflers, dress goods and blouse silks; also for mixing with other fibres in form of stripes in the weaving of various fabrics, or to be used in what are known as mixed goods, *i.e.*, a warp of silk and weft of some other fibre or weft of silk and a warp of cotton or other fibre. The article known as tussur spun is prepared in exactly the same manner as other spun silks, but its chief use is to make an imitation of sealskin known commercially as silk seal.

SILK TRADE. The area suitable for sericulture stretches in a broad belt between 25° and 48° of latitude right across Europe and Asia. It is China and Japan which produce 85·5 per cent. of the world's supply of raw natural silk as the following table, taken from the League of Nations Report for 1927 (C.E.I. 24, page 6), indicates.

Production 1925			World percentage
Western Europe		Kilogrammes	
Spain	100,000		
France	265,000	4,740,000	11·7
Italy	4,380,000		
Eastern Europe and the Levant		1,065,000	2·6
The Far East			
India and Indo-China	90,000		
China	8,120,000	34,055,000	85·5
Japan	25,845,000		
Approx.		39,860,000	..

The above figures show the quantity of silk available for western manufacturers, but the actual production of both China and Japan is far higher, the figures shown being merely those of the exports of raw silk from these two countries. The home consumption of China is estimated as at least 55% of her total production, being mostly worked upon hand looms, whilst in the case of Japan, about 30% is used at home, and so the above figure represents only 45% of the total output of China and 70% of that of Japan. Moreover, in the case of the latter country much of the raw material is worked up by modern machinery whose products are subsequently sold in competition with European silk manufactures.

It is believed therefore that the actual world production of raw silk is not less than 58,000,000 kg., worth approximately £175,000,000 or $830,000,000, whereas the commercial supply available for European and American manufacturers is only 39–40,000,000 kilogrammes.

In 1875, western Europe produced about 46% of the world's commercial supplies of natural silk, but by 1925 it was barely 12%. In that year the value of the commercial crop was £120,-000,000. It will thus be seen that without reducing shipments of raw silk to Europe and America, China and Japan have an ample supply of raw silk with which to produce increasing quantities of silk manufactures and sell them in competition with the products of western manufacturers. One factor must be noted and that is that despite the impoverishment of Europe by the World War and the increasing output of artificial silk, the demand for natural silk products has steadily increased during the last ten years, and so has the total production of raw silk. The demand is due in part to the present fashions, and in particular for silk hosiery of all types, and in part to the increasing use of silk mixed with other textile yarns in all manner of products.

Consumption of Silk Goods.—Although it is not possible to give accurate figures of the world's output of finished silk goods, a very fair picture will be obtained from a study of the statistics of consumption. According to *The Economic Forces of the World* issued by the Dresdener bank of Berlin in 1927, the world consumption of raw silk in 1913 was 29,250,000 kg. Of this France used 17·3%, Germany 13·7, Italy 5·5 and all Europe together took 39·9 per cent. Of the remainder the United States consumed 40·3%, China 9·9 and Japan 6.8. By 1925 the world

total had risen to 46,350,000 kg. and the United States had increased her lead to 61·7%, France had sunk to 13·1% and Germany to 4·5%. The consumption of the rest of Europe had also decreased so that the total was only 21·1%, while in Asia Japan was the only exception, her consumption having risen to 9·7 per cent.

Number of Looms.—In the 20th century two tendencies have been most noticeable: the first is the gradual replacement of the handloom by the mechanical loom and the second is the steadily increasing importance of the United States as a manufacturer of silk goods. The consumption figures have already shown this tendency but the figures of the number of looms are even more striking. So far as the hand looms are concerned, in 1913 Europe owned 29,300 out of a total of 69,300 or 42·4%, practically all the rest being Japanese, for although China and India used handlooms their products hardly competed commercially, being almost exclusively used at home.

By 1925 the European handlooms had sunk to 23,400, while in Japan the number had remained stationary. Of the European handlooms more than half belong to France.

The real future of the silk industry rests, however, with the mechanical loom and here the progress has been marked. In 1913 Europe owned 152,800 out of a world total of 244,800 or, in other words, 62·4 per cent. The United States owned 84,000 or 34·3% and Japan 8,000 or 3·3 per cent. By 1925 the world total had increased to 268,100, of which the United States owned no less than 102,000, while those belonging to European countries had only increased to 154,100 as compared with the increase in Japan to 12,000. Therefore in that year Europe owned only 57·5% of the total as compared with 62·4% in 1913, whereas the United States owns 38% and Japan 4·5 per cent.

Commerce in Silk.—Lyons is still the headquarters of the silk trade in France, Krefeld in Germany, Genoa in Italy, Zurich in Switzerland and Macclesfield in England, although there are many other places where particular lines are made and distributed.

In 1927 Great Britain imported raw silk worth £1,831,600 and articles manufactured worth £16,190,000 and only exported goods worth £2,427,000. India purchased abroad silk goods worth 4,71,54,193 rupees, of which raw silk and waste represented 1,37,94,765 rupees and only exported 40,12,400, of which 35,01,000 rupees represented raw silk. It is clear, therefore, that as yet she plays but a small part in the production and distribution of manufactured silk goods. China on the other hand imports but little silk, whereas she supplies approximately 22 per cent of the total commercial crop. The value of her total silk exports in 1926 was 191,675,975 Haikwan taels. This total included silk piece goods worth 21,364,100 Haikwan taels and shows that, despite her primitive methods, she is able to sell large quantities of finished goods, a fact which suggests that as she changes to the mechanical loom she will tend to become a more serious competitor both of Europe and the United States. Japan has already progressed a fair way along the road on which China is only just embarking. Handlooms still play an important part in the production of the goods she sells abroad, but it is her mechanical looms which are increasing. That she is now an important factor in the silk trade may be demonstrated by the fact that in 1926 her exports of tissues were five times as great as those of Great Britain. In 1927 her silk imports were trifling and consisted almost entirely of cocoons and wild silk, but her exports were large and included such items as raw silk worth 740,611,000 yen and tissues 139,615,000 yen. Heavy imports of raw silk in America show that the trade consists in producing finished goods for the home market whereas her imports of finished goods are small and only exceed her exports by a trifling amount. Thus in 1927 the United States imported raw silk worth $390,365,000 and fabrics worth $17,862,000, while her exports were worth $15,298,000.

In Europe France is the chief centre of the silk trade. She imported in 1927 raw silk worth 1,678,180,000 francs, weighing 120,486,000 kilogs., spun silk and thread worth 46,443,000 francs and tissues worth 100,238,000 francs and exported raw silk, spun silk and thread, etc., worth 720,495,000 francs and manufactured goods worth 3,233,511,000. We must remember, however, that in that year the mean rate of exchange for the franc was 123·87 francs to the £. Of the remaining European countries the most important are Italy and Germany. In 1927 the former imported manufactured silk goods worth 393,270,000 lire, of which 63,000,000 represented cocoons and 130,872,000 thrown silk. Of her exports the most important items were thrown silk 803,293,000 lire, and doubled and twisted 645,629,000 and she sold waste silk worth 179,000,000 and tissues worth 943,370,000 lire.

Germany suffered severely during the post-war crisis and is only gradually recovering her former position. In considering her statistics we must remember that they include artificial silk, which should be excluded but cannot be disentangled. The gold mark in 1927 was worth 11·74d., in which year she imported approximately 200,000,000 marks worth of raw and thrown silk, yarn and tissues and exported 258,800,000 marks worth, of which only 4,111,000 was classified as raw and thrown. Her two chief items were tissues and hosiery, which between them accounted for nearly four-fifths of her exports. (J. S. M. W.)

SILL, EDWARD ROWLAND (1841–1887), American poet and educationist, of Puritan ancestry, was born at Windsor (Conn.), April 29, 1841. Early orphaned, he drifted through college, recognized as a genius, but out of sympathy with the Puritanic atmosphere and academic formalism of Yale at the period. After his graduation in 1861, he had difficulty in finding his proper niche. He spent five years in California, working in a post-office, on a ranch, and in a bank, and for a time studying medicine and law. On his return to the East, he entered the Harvard Divinity school, but felt that he could not conform to church dogmas and tried newspaper work in Brooklyn, where he "didn't suit, wasn't suited, and quit." After a brief experience of teaching in a rural school, he was, from 1869 until 1871, principal of the high school and superintendent of the grades in Cuyahoga Falls, Ohio, the home of his "best uncle," his wife's father. Thereafter he taught at the Oakland (Calif.) high school, and he was professor of English in the University of California, at Berkeley, from 1874 to 1882. The remainder of his life was devoted to literary work at Cuyahoga Falls. He died unexpectedly, after a minor operation, at Cleveland, Ohio, Feb. 27, 1887. Sill was devoted to music, and had some talent in painting. Of an unusually sensitive temperament, he liked best to work in seclusion, and much of his work in the *Atlantic* and other magazines appeared anonymously in "The Contributors' Club" or under a pseudonym. The reception of his first book, *The Hermitage and Other Poems* (1868), was disappointing; and although *The Venus of Milo and Other Poems* (1883) was privately printed as a farewell to his California friends, he published no other book during his lifetime. His best poems, such as "The Fool's Prayer" and "Opportunity," gave him a place among the minor poets of America, which might have been higher but for his early death.

A memorial volume was privately printed by Sill's friends in 1887. *See* the biographical sketches in *The Poetical Works of Edward Rowland Sill* (1906), and in his collected *Prose* (1900); also *Edward Rowland Sill, His Life and Work* (1915), by W. B. Parker.

SILL (O.Eng. *syl*, Mid. E. *sylle*, selle; the word appears in Icel. *syll*, *svill*, Swed. *syll*, and Dan. *syld*, and in German, as *Schwelle*; Skeat refers to the Teutonic root *swal-*, swell, the word meaning the rise or swell formed by a beam at a threshold; the Lat. *solea*, from which comes Fr. *seuil*, gives Eng. "sole," also sometimes used for "sill"), the horizontal base of a door or window-frame. A technical distinction is made between the inner or wooden base of the window-frame and the stone base on which it rests—the latter being called the sill of the window, and the former that of its frame.

SILL, in geology, an intrusive mass of igneous rock which consolidated beneath the surface and has a large horizontal extent in comparison with its thickness. In north-eastern England there is a great mass of this kind known as the Whin Sill. "Whin" designates hard, tough, dark coloured rocks often of igneous origin, and the Whin Sill is a mass of dolerite or, more strictly, quartz-dolerite. Its most striking character is the great distance over which it can be traced. It starts not far north of Kirkby Stephen

(Westmorland) and describes a great curve with its convexity towards the west, till it ends on the sea-shore at Bamborough, not far south of Berwick-on-Tweed. It has been pierced in a deep boring at Crook, in Durham. The length of the outcrop is about 80 m., but in places it is covered with superficial deposits or may be actually discontinuous. The rocks in which it lies belong to the Carboniferous Limestone series, and the sill is probably one of the manifestations of the volcanic activity which occurred during the later part of the Carboniferous period.

The Hudson Palisades.—The great Palisade trap of the Hudson river, which is an almost exact parallel to the Whin Sill, is an enormous sheet of igneous rock exposed among the Triassic beds of New Jersey and New York. It has an outcrop which is about 100 m. long; its thickness is said to be in places 800 ft., though usually not above 200 to 300 ft. Like the Whin Sill the rock is a quartz-dolerite occasionally passing into olivine-dolerite, especially near its edges. The Palisade dolerite is compact, non-vesicular and non-porphyritic as a rule. It follows the bedding planes of the sedimentary rocks into which it was injected, but breaks across them locally and produces a considerable amount of contact alteration. These great sheets of igneous rock intruded into cold and nearly horizontal strata must have solidified very gradually. Their edges are fine-grained owing to their having been rapidly chilled, and the whole mass is usually divided by joints into vertical columns, which are narrower and more numerous at top and base and broader in the centre. Where exposed by denudation the rocks, owing to this system of jointing, tend to present a nearly vertical, mural escarpment which seems to consist of polygonal pillars.

Sills of Scotland and Ireland.—In the Tertiary volcanic district of the west of Scotland and north Ireland, including Skye, Mull and Antrim, innumerable sills occur and intrusive sheets build up a great part of the geological succession. They are for the most part olivine-basalts and dolerites, and while some of them are nearly horizontal, others are inclined. Among the lavas of the basaltic plateaus there is great abundance of sills, which are so numerous, so thin and so nearly concordant to the bedding of the effusive rocks that there is great difficulty in distinguishing them. As a rule, however, they are more perfectly columnar, more coarsely crystalline and less vesicular than the igneous rocks which consolidated at the surface. These sills are harder and more resistant than the tuffs and vesicular lavas, and on the hill slopes their presence is often indicated by small vertical steps, while on the cliff faces their columnar jointing is often very conspicuous.

Modern Volcanic Sills.—On modern volcanoes intrusive sheets are seldom visible except where erosion has cut deep valleys into the mountains and exposed their interior structure. This is the case, for example, in Ireland, Teneriffe, Somma and Etna and in the volcanic islands of the West Indies. In their origin the deep-seated injections escape notice; many of them in fact belong to a period when superficial forms of volcanic action have ceased and the orifices of the craters have been obstructed by ashes or plugged by hard crystalline rock. But in the volcanoes of the Sandwich islands the craters are filled at times with liquid basalt which suddenly escapes, without the appearance of any lava at the surface. The molten rock, in such a case, must have found a passage underground, following some bedding plane or fissure, and giving rise to a dike or sill among the older lavas or in the sedimentary rocks beneath. Many of the great sills, however, may have been connected with no actual volcanoes, and may represent great supplies of igneous magma which rose from beneath but never actually reached the earth's surface.

Sills and Dikes.—The connection between sills and dikes is very close; both of them are of subterranean consolidation, but the dikes occupy vertical or highly inclined fissures, while the sills have a marked tendency to a horizontal position. Accordingly we find that sills are most common in stratified rocks, igneous or sedimentary. Very frequently sills give rise to dikes, and in other cases dikes spread out in a horizontal direction and become sills. It is often of considerable importance to distinguish between sills and lavas, but this may be by no means easy. Lavas indicate that volcanic action was going on contemporaneously with the deposit of the beds among which they occur. Sills, on the other hand, show only that at some subsequent period there was liquid magma working its way to the surface.

SILLIMAN, BENJAMIN (1779–1864), American chemist and geologist, was born on Aug. 8, 1779, at Trumbull (then called North Stratford), Connecticut. Entering Yale college in 1792, he graduated in 1796, and in 1802 was appointed professor of chemistry and mineralogy, a position which he retained till 1853. Not only was he a popular and successful teacher of chemistry, mineralogy and geology in the college for half a century, but he also did much to improve and extend its educational resources, especially in regard to its mineralogical collections, the Trumbull gallery, the Medical institution and the Sheffield Scientific school. Outside Yale he was well known as one of the few men in America who could hold the attention of a popular audience with a scientific lecture. His original investigations were neither numerous nor important, and his name is best known to scientific men as the founder, and from 1818 to 1838 the sole editor, of the *American Journal of Science and Arts*—often called *Silliman's Journal*—one of the foremost American scientific serials. He died at New Haven (Conn.) on Nov. 24, 1864.

SILLIMANITE, a rock-forming mineral of composition Al_2SiO_5, crystallizing in the rhombic system. Sillimanite has the same percentage of chemical composition as andalusite (*q.v.*) and kyanite (*q.v.*) but differs from these in crystalline form and physical properties. The crystal habit is that of long slender prisms, often aggregated together to form fibrous or compact masses (hence its alternative name, fibrolite), but terminal faces are very rare. The mineral possesses a perfect cleavage parallel to 010, and an irregular cross parting parallel to 001 is usually observed in thin slices under the microscope.

The pure mineral is white, but coloured varieties are pleochroic, the colour being ascribed to Fe_2O_3 or TiO_2. Rare sapphire-blue crystals of gem quality from the Burma ruby mines have yielded good faceted stones.

Sillimanite is stable at all temperatures below 1,545° C, at which temperature it dissociates into the compound $3Al_2O_3 \cdot 2SiO_2$ (mullite) (*q.v.*) and a silica-rich liquid. It is doubtful whether sillimanite has yet been artificially prepared. Sillimanite is essentially a mineral of the crystalline schists and hornfelses, being especially characteristic of highly metamorphosed argillaceous sediments. As such it is commonly found in the thermal aureoles of igneous intrusions and in areas of crystalline schists of the highest grade of metamorphism. Cordierite, corundum, spinel and potash felspar are common associated minerals. (C. E. T.)

SILO: *see* ENSILAGE.

SILURES. These were a powerful and warlike tribe in ancient Britain, occupying approximately the counties of Monmouth, Brecon, and Glamorgan. They made a fierce resistance to the Roman conquest about A.D. 48, but a legionary fortress (Isca Silurum, Caerleon) was planted in their midst and by A.D. 78 they were overcome. Their town Venta Silurum (Caerwent, 6 m. W. of Chepstow) became romanized. Its massive Roman walls survive, and excavations have revealed a town hall and market square, a temple, baths, amphitheatre, etc.

SILURIAN SYSTEM, a term variously used in geology; as originally defined by Murchison in 1835 it included the rocks developed on the borders of England and Wales, a region formerly inhabited by the Silures; now used in Britain in a restricted sense to denote rocks lying between the Ordovician system below and the Old Red Sandstone or Devonian system above. There is no complete agreement as to the exact horizon at which the lower and upper limits of the system should be drawn. The upper limit of the Ashgillian has yet to be defined accurately in those areas where sedimentation proceeded continuously from Ordovician to Silurian time; and opinion is somewhat divided as to the upward limitation of the system, on the one hand on account of the physical conditions attending deposition where the Old Red Sandstone facies succeeds, and on the other from the difficulty of putting a definite boundary where there is a gradual passage, owing to continuous sedimentation under the open sea conditions that usher

in the Devonian facies.

As is the case with the rocks of the ORDOVICIAN system the strata belonging to the SILURIAN system may be divided into several contemporaneous facies or types of deposit controlled by different physical conditions; four main facies can be recognized:

1. TERRESTRIAL: only known in America.
2. SHALLOW WATER:
   (a) areas of heavy sedimentation, *i.e.*, littoral areas.
   (b) areas of average sedimentation, sandstones and mudstones.
   (c) clean sea areas of reef formation and shell-bank growth.
3. DEEPER WATER GRAPTOLITE SHALES.
4. VOLCANIC: mainly in Australia and America.

Again, as in the Ordovician Period, the deposits belonging to the shallow water facies may pass into each other laterally, *i.e.*, in a direction parallel to the original shore line, whilst in a direction at right angles to this shore line they pass into the deeper water Graptolite Shales, and as this transition often takes place gradually, the shallower water beds being replaced stage by stage, the contemporaneity of the two is placed beyond doubt.

Life.—The life of the SILURIAN PERIOD, though somewhat similar in general aspect to that of the ORDOVICIAN, presents a definite advance in type, and more classes of organisms play a prominent part.

It may be said to be characterized:—

(a) By the rise of the spine-bearing brachiopods (e.g., *Atrypa, Meristina*) and the great development of those with a definite internal skeleton (*Pentamerus*). The Silurian is pre-eminently the age of brachiopods.

(b) by the abundance of trilobites, though as these have passed their zenith there are but few new genera, and these of no great importance.

(c) by the predominance of the uniserial scandent graptolites (*Monograptus*).

Other noteworthy features are:—

(d) the rise in importance of the mollusca as a whole, especially the *Cephalopods*, the earliest *Ammonoid* making its appearance.

(e) the incoming late in the period of the first vertebrates (fish).

(f) the increased importance of corals and crinoids, especially as rock-builders.

(g) the abundance towards the close of crustaceans of *Eurypterus* type.

The shallow water fauna is predominantly a brachiopod-trilobite fauna, characterized by mutations of *Pentamerus* (including the subgenera *Barrandella, Conchidium, Sieberella*, etc.), though in some places it is less prominent than *Stropheodonta*, and in the higher beds *Rhynchonella* (*Camarotaechia*) and *Chonetes* predominate. In the cleaner waters, which seem to have occupied wide areas, there seems to have been considerable reef-building,

not only by corals but by other classes of organisms such as bryozoa, crinoids and stromatoporoids. Brachiopods also, together with other organisms, gave rise to considerable shell-banks of limestone.

The fossils of commonest occurrence are:—

Trilobites	*Phacops Sensu lato, Calymene, Encrinurus, Acidaspis, Lichas, Cheirurus, Homolonotus, Illaenus, Arethusina, Proetus, Sphaerexochus.*
Brachiopods	*Pentamerus Sensu lato, Stricklandinia, Meristina, Stropheodonta, Atrypa Coelospira, Plectambonites, Leptaena, Camarotaechia, Wilsonia, Dayia, Chonetes, Dalmanella, Whitfieldella.*
Corals	*Halysites, Heliolites, Favosites, Acervularia, Omphyma, Palaeocyclus, Goniophyllum, Syringopora.*
Cystids	*Lepadocrinus, Prunocystis, Schizocystis.*
Crinoids	*Cyathocrinus, Crotalocrinus, Taxocrinus, Periechocrinus.*
Crustaceans	*Eurypterus, Pterygotus, Slimonia.*
Cephalopods	*Orthoceras, Gomphoceras, Trochoceras, Phragmoceras, Ascoceras.*
Lamellibranchs	*Orthonota, Cardiola, Aviculopecten, Pterinaea, Modiolopsis, Grammysia.*

In the Graptolitic facies Monograpti predominate throughout; in the earlier beds they have either simple cells or cells with a slight degree of sinuosity, but they then tend to show a development into a lobe or hook on the one hand, or to isolation of the cells from each other on the other; thus the lobed cell and the isolated cell are characteristic of the Valentian, the hooked cell of the lower part of the Salopian, and the return to simple form the upper part of the Salopian. In general, graptolites are rare above the Salopian, but some have been recorded from Bohemia from beds of Downtonian age.

Distribution.—Rocks of Silurian age are found in many lands all over the world; they occur in Europe in the British Isles, Scandinavia, Estonia, Livonia, Russia, France, Belgium, Germany, Poland, Bohemia, Spain, Elba and Sardinia; in Asia, in Siberia, China, the Himalayas and in the Shan States; in N. and S. America; in N. Africa and in Australia.

Europe.—With the exception of those occurring in E. Scandinavia, Estonia, Livonia and Russia, the beds in Europe have been in general highly folded by earth movements, but even so may be grouped according to their facies of deposit; they seem to have occupied much the same areas as those of the Ordovician, and it is clear from the study of the rocks accumulating throughout the period in the N.W. geosyncline, that the stresses were in operation that were eventually to culminate in the elevation of the Caledonian-Scandinavian mountain system, for the shore lines of the gulf are continually shifting their position, and as a result intra-formational conglomerates are frequently found, and there is a marked tendency for succeeding beds to overlap; moreover, oscillations of the shore line gave origin to a widespread continental shelf with its island festoon affording ideal conditions for the reef-building by corals and other organisms, or for the formation of shell-banks made up largely of the remains of one class of organism. Outside the geosyncline also clean sea limestone reefs or graptolite shales are of widespread occurrence. The island of Gotland may be taken as typifying the former, the development in Skåne or Bohemia as characteristic of the latter facies of deposit.

The British Isles.—The general instability of the shore lines of the geosyncline is admirably illustrated by the rock succession in S. Scotland on the one hand and the Welsh borderland on the other; in S. Scotland the shore line moved more or less steadily towards the S.E., so that deeper water beds are continually being overlaid by those of shallower water type. In the Welsh borderland the oscillations were far more irregular; sometimes the sea transgressed with overlap and unconformity upon the eastern shore line, at others there was a retrogressive movement when the shore line advanced so that there is great variety in different places, not only in the sediments found, but also in the completeness of the succession. One fact remains constant, namely, that

when far enough away from the shore line, these variable deposits all tend to pass into graptolite shales until the area of the gulf has become so shallow that the shallow water facies occupies the whole.

Scandinavia.—Skåne alone possesses a complete series of beds of Silurian age; for the greater part these belong to the graptolite shale facies, but include shallower water beds towards the top: over much of the remainder of the country the strata of this period are found in the table-topped hills capped by dolerite in which only a part of the succession is found.

America.—The Silurian rocks of America are not exposed so extensively as were those of Ordovician age; at present little is known about their character in the west, the best known successions being found in the east and centre, though they are also known in the north; in the eastern region the succession is of interest, as a volcanic facies occurs in addition to those of shallow and deeper water type and in many respects, apart from the volcanic rocks, the succession resembles that of the British Isles; the central region contains the classic development exposed in the Niagaran Gorge (*see* table); the rocks are thickest in the Appalachian region, and thin away towards the interior where the series tends to be incomplete as the result of unconformity or overlap. There is a very general absence of rocks of Lower Valentian age. In the north the development, which includes islands in the Arctic archipelago, consists very largely of coral limestones.

Australia.—Strata of Silurian age appear to be restricted wholly to the east part of the continent, being found only in Queensland, New South Wales, Victoria and Tasmania, where they have been considered as originating in Schuchert's "Tasmanian geosyncline." They are mainly of interest as affording evidence of submarine volcanic activity during the period, this being most conspicuously displayed in New South Wales; apart from this, records indicate the occurrence of the common facies of deposition. In Tasmania the rocks are mainly of shallow water type, and in Victoria where they have been considerably affected by earth movement, they are distinguished by the development of fringing reefs of coral limestone. Graptolite shales with characteristic *Monograpti* have also been recorded.

SILVA, ANTONIO JOSÉ DA (1705–1739), Portuguese dramatist, was born at Rio de Janeiro, Brazil, but came to Portugal with his parents at the age of eight. The parents belonged to a French family which had emigrated to escape the Inquisition. Antonio was sent to study at Coimbra, and, while still a student, was arrested with his mother. Both were tortured, but Antonio abjured his errors, and his mother figured as a penitent in an *auto-da-fé.* He completed his studies and joined his father in practice as an advocate at Lisbon. He married a cousin whose parents had been burnt by the Inquisition, while she also had been exiled for her religion. On Oct. 5, 1739, husband and wife were imprisoned for "judaizing," having been denounced by the Inquisition. On Oct. 18 Antonio was strangled, and his body burnt in an *auto-da-fé;* on that same day one of his popular operettas was given at a Lisbon theatre.

His dramatic works, which were produced at the Bairro Alto theatre between 1733 and 1738, include the following comedies, all played by marionettes:—*D. Quixote* (1733), *Esopaida* (1734), *Os Encantos de Medea* (1735), *Amphitrião* (May 1736), *Labyrintho de Creta* (November 1736), *Guerras do Alecrim e Mangerona* (carnival of 1737), *As Variedades de Proteo* (May 1737) and *Precipicio de Faetonte* (1738). Slight as these sketches are, they show considerable dramatic talent and an Aristophanic wit. The characters are well drawn and the dialogue full of comic strength, the scenes knit together and the plot skilfully worked out. Moreover Silva possessed a knowledge of stagecraft, and, if he had lived, he might have emancipated the drama in Portugal from its dependence on foreign writers; but the triple licence of the Palace, the Ordinary and the Inquisition, which a play required, crippled spontaneity and freedom. Even so, he showed some boldness in exposing types of the prevailing charlatanism and follies, though his liberty of speech is far less than that of Gil Vicente (*q.v.*). His comedies give a truthful and interesting picture of 18th century society, especially his best comedy, the *Alecrim e Mangerona,* in which he treats of the *fidalgo pobre,* a type fixed by Gil Vicente and Francisco Manoel de Mello (*q.v.*).

Bibliography.—His plays were published in the first two volumes of a collection entitled *Theatro comico portuguez,* which went through at least five editions in the 18th century, while the *Alecrim e Mangerona* appeared separately in some seven editions. This comedy and the *D. Quixote* have been reprinted in a critical edition with a life of Silva by Dr. Mendes dos Remedios (Coimbra, 1905). Ferdinand Denis, in his *Chefs-d'oeuvre du théâtre portugais* (pp. 365–496, Paris, 1823), prints liberal extracts, with a French translation, from the *Vida de D. Quixote.*

SILVANUS (Lat. *silva,* wood), a deity or spirit of the woodland bordering on clearings. Thus he is partly wild and partly civilized, and reflects the experience of the earliest settlers in Italy; hence his later identification with foreign deities felt to be not wholly hostile. Accordingly Horace writes of the "horridi dumeta Silvani" (*Odes,* iii. 29) but he also calls him "tutor finium" (*Epod.,* ii. 22) and Virgil "arvorum pecorisque deus" (*Aen.* viii. 600). A writer on land measurement (*Script. gromatici,* i. 302) tells us that each holding had three Silvani—*domesticus* (of the holding itself), *agrestis* (of the wilder pasture-land) and *orientalis* (of the boundaries). Although much worshipped, he never made his way into the towns, but is almost the only Roman deity who from first to last retained the same perfectly intelligible rustic character. His double nature as deity of woodland and cultivated land is seen well in the artistic representations of him; he carries a young tree in one hand, a pruning-hook in the other.

See Wissowa, *Gesammelte Abhandlungen* (1904, p. 78 foll.).

SILVER, a metal known from very early times and, on account of its comparative scarcity, brilliant white colour, and resistance to atmospheric oxidation, has long been used for articles of value—coins, ornaments and jewellery. Silver (symbol Ag, atomic number 47, atomic weight 107·88) was called Luna or Diana by the alchemists, who assigned to it the symbol of the crescent moon; the term lunar caustic is still in general use for silver nitrate.

Silver is very widely diffused throughout nature as is shown by spectrum analysis; it is always present in sea water in minute amounts, an estimate of the total amount present being 2,000,000 tons. Silver is sometimes found native—usually in only small quantities, though occasionally masses of several hundredweights have been discovered.

Gold is almost invariably found associated with silver. The principal ores of silver are the sulphides, and to a lesser extent it is found combined with tellurium, selenium, arsenic and antimony. Galena, PbS, always contains silver and most of the metal produced in Europe comes from this source.

Physical Properties.—Silver in the massive state is the whitest of all metals, has a perfect metallic lustre, and is the most malle-

able and ductile of all metals except gold: one gram of the pure metal can be drawn out into wire considerably more than one mile long, and it can be beaten into leaves of a thickness of 0·00025 mm. Hammering or rolling hardens the metal considerably, but the malleability is restored by annealing at a dull red heat. Pure silver is somewhat harder than gold but softer than copper; it is too soft in the pure state for use as coinage or jewellery, and for these purposes it is best hardened by alloying it with a small percentage of copper which neither affects its colour appreciably nor renders it brittle. The specific gravity of silver varies considerably according to the previous method of treatment, the density of different samples varying from 9·87 to 10·55, whereas the density of silver precipitated from solution by ferrous sulphate is 10·62. A mean value of 10·5 may be taken as fairly correct. The specific heat of silver is about 0·56 and its coefficient of linear expansion between 0° and 100° C is about 0·0000194, but this increases rapidly at higher temperatures.

Silver is by far the best conductor of heat and electricity. According to the law of Wiedemann and Franz, the ratio of heat-conductivity to electrical-conductivity of good conducting metals is constant at the same temperature. Taking the thermal conductivity of silver as standard (100), the thermal conductivities of other metals are as follows:

Ag	Cu	Au	Zn	Sn	Fe	Pt	Pb	Bi
100	73·6	53·2	19·0	14·5	11·6	8·4	8·1	1·8

The melting point of silver is 960·5° C, and its boiling point under atmospheric pressure is about 2,000° C. It gives rise to a blue vapour which on dilution in the atmosphere appears bright green. Its vapour density has been determined at a temperature above its boiling point, and the molecule thereby found to be monatomic. In the molten state silver has the property of "occluding" about 20 times its volume of oxygen. This oxygen is not in a state of chemical combination and is violently ejected on cooling to near the solidifying point, producing a phenomenon known as the "spitting" of silver. The absorption of oxygen from the air can be prevented by covering the surface either with powdered charcoal or with some non-oxidising flux.

Chemical Properties.—Silver does not combine directly with oxygen, nor does it decompose water or steam at any temperature; it is, however, oxidized by ozone which becomes converted into ordinary oxygen without alteration in volume. The ordinary blackening or discoloration of silver is invariably caused by sulphur, either in the free state or in compounds other than oxides. This stain is black silver sulphide, Ag_2S.

Silver dissolves readily in nitric acid, either strong or dilute, producing the nitrate, $AgNO_3$, with evolution of nitric oxide; it is also readily soluble in hot strong sulphuric acid, silver sulphate, Ag_2SO_4, being produced with evolution of sulphur dioxide. Hydrochloric acid acts superficially on silver, but further action is stopped by the coating of silver chloride produced. Hydriodic acid dissolves silver readily, producing the iodide but hydrofluoric acid is without action on it. Silver combines readily with the free halogens.

"Molecular" Silver.—Silver can be obtained in a finely divided, very reactive state as a greyish powder either by precipitation of a solution by a reducing agent, such as ferrous sulphate, or by bringing a piece of a more electro-positive metal such as iron or zinc into contact with a silver halide below faintly acidified water. This active form of the metal is usually dried at a low temperature after thorough washing, and is frequently used in organic synthesis for removing halogen elements from alkyl compounds with duplication of the organic radical.

Colloidal silver may be produced by precipitating a solution of silver nitrate with various organic substances such as tartrates, citrates, tannin, etc. The precipitates vary greatly in colour, and after washing become soluble in pure water. A brown colloidal solution of silver may also be obtained by passing an electric arc between silver terminals under pure water.

Silver in any form acts catalytically upon solutions of hydrogen peroxide; a steady stream of oxygen flows from the points of contact and finally complete decomposition results.

Chemically Pure Silver.—In exact determinations of the atomic weights (*q.v.*) of elements (halogens, etc.), it is frequently necessary to obtain silver in the purest possible state and a great deal of work has been done to this end. For a long time the most satisfactory process was the reduction of a solution of silver nitrate by means of ammonium sulphite, but this process, due to J. S. Stas, has been superseded by that of Richards and Wells (1905), which is carried out as follows: A solution of recrystallized silver nitrate is precipitated by hydrochloric acid and the resulting chloride thoroughly washed. This chloride is then placed in a silver dish and reduced to metallic silver with pure invert sugar and caustic soda. The reduced silver is fused on a block of lime in the reducing flame of a blowpipe, and thereby brought to 99·999% purity; this is made the anode and cathode of a cell, the electrolyte being a solution of silver nitrate prepared from some of the same purified silver. On electrolysis a crystalline powder of electrolytic silver is formed, and is thoroughly washed, dried and fused in a lime boat contained in a tube through which a current of hydrogen is circulated. The small bars of silver after scrubbing and washing with dilute nitric acid, ammonia and water are dried *in vacuo* at about 400°.

Alloys.—Silver alloys readily with most metals, but in many cases the alloys are of little practical value; thus arsenic, antimony, bismuth, tin and zinc produce very brittle alloys which are quite unsuitable for further working. Copper on the other hand increases its hardness, toughness and fusibility, and such alloys are therefore almost exclusively used for coinage and jewellery. The proportion of silver in alloys is stated in terms of its "fineness" which means parts of silver in 1,000 parts of the alloy. Thus the British coinage till 1920 was of a fineness of 925 or 92·5% silver and 7·5% copper, and was well adapted to its purpose, but the silver currency was then lowered to a fineness of 500, and other metals besides copper, especially nickel, were introduced. This alloy is much less satisfactory than that of the old standard for, apart from its unsatisfactory working properties, it is much more readily discoloured.

Silver is sometimes alloyed with gold and with the platinum metals, with which it produces alloys which can be worked satisfactorily. Thus the sovereigns formerly minted in Australia were of 22-carat quality, containing 8·33% silver instead of copper, and thus having a lighter colour; and a dental alloy of 50% silver-platinum was at one time in general use.

Compounds of Silver.—Several oxides of silver have been reported from time to time. A suboxide, Ag_4O, has been stated to exist by several observers, but their results have not been generally accepted. The best characterized oxide is the compound Ag_2O, argentic oxide, which is the base of all the more stable salts of silver. It is produced by precipitating a solution of silver nitrate by an alkaline or alkaline-earth hydroxide, as a blackish powder which can be crystallized from solutions of ammonia, forming violet crystals. This oxide is appreciably soluble in water (1 part in 300) giving a solution which turns red litmus blue, and which precipitates most of the heavy metals as hydroxides. This oxide is a strong base and forms stable salts with acids. It begins to decompose into its elements at 250°.

Silver peroxide, AgO or Ag_2O_2, is formed by the electrolysis of silver solutions under certain conditions, or by the action of potassium permanganate upon argentic oxide. That formed by electrolysis is generally found combined with some of the silver salt forming the electrolyte, and compounds such as Ag_7NO_{11} and $Ag_{14}S_2O_{24}$ are said to have been produced. Higher oxides of silver have been reported but not confirmed.

Halogen Compounds.—Silver combines with all the halogens to form definite and very stable compounds. Silver chloride, $AgCl$, is found native in the mineral horn-silver or cerargyrite; mixed with clay, it is called butter-milk ore by the German miners. It is obtained as a precipitate by the action of hydrochloric acid or any soluble chloride upon a solution of silver. It forms a white curdy precipitate which rapidly darkens on exposure to light, and this reaction is the basis of nearly all the processes used in photography (*q.v.*). Silver chloride is nearly insoluble in pure water and in dilute nitric acid (1 part in 50,000). It is, however, much

more soluble in concentrated solutions of hydrochloric acid and metallic chlorides, although, on dilution, most of the silver chloride is often precipitated. Silver chloride dissolves readily in ammonia and evaporation of the solution yields rhombic crystals of the composition $2AgCl,3NH_3$. It is also easily soluble in solutions of sodium thiosulphate and potassium cyanide. Silver chloride melts at about 455° C to a yellow transparent liquid, which, on cooling, solidifies to a colourless horny mass. It is easily reduced to metallic silver (1) by contact under acidulated water with certain metals (zinc, iron, etc.), an equivalent of which dissolves as chloride; (2) by fusion with alkaline hydroxides, carbonates or cyanides; (3) by heating in a stream of hydrogen or coal gas; or (4) by digesting alkaline solutions with grape sugar or other reducing agents.

Silver bromide, AgBr, found native in the mineral bromargyrite in Chile and Mexico, is obtained as a yellowish-white precipitate by the addition of a soluble bromide to a silver solution. It resembles the chloride in most of its properties but is less soluble in ammonia. It melts at about 425° C, and is even more sensitive to light than the chloride, although its change in colour is less noticeable. Certain minerals, chiefly found in Chile, consist of variable mixtures of AgCl and AgBr; they are embolite, megabromite and microbromite. Silver iodide, AgI, found native in the mineral iodargyrite or iodyrite, is produced by precipitating a silver solution with any soluble iodide or by acting upon the metal with hydriodic acid or iodine. It forms a yellow powder, practically insoluble in water, acids, or ammonia, but soluble in strong hydriodic acid, sodium thiosulphate, or strong solutions of potassium iodide, forming in the last case a double iodide, $KAgI_2$. Silver iodide is dimorphous; at ordinary temperatures it is hexagonal and deep yellow, but at 146° C it changes to a cubic, light yellow form. Like the chloride and bromide, it is partly decomposed by light, but without apparent change of colour as it requires a developer to demonstrate the change. Silver iodide melts at 552° C, and after resolidifying it shows the anomalous behaviour of expansion on cooling.

Silver fluoride, AgF, produced by dissolving the oxide in hydrofluoric acid, is soluble in water, the solution possessing an alkaline reaction; it crystallizes with one molecule of water and is unacted on by light.

Other Compounds.—Silver nitrate, $AgNO_3$, by far the most important compound of silver, is almost always produced by dissolving the metal in somewhat diluted nitric acid and crystallizes on evaporation of the solution as anhydrous, colourless, rhombic plates. Silver nitrate is exceedingly soluble in water, dissolving in less than half its own weight at ordinary temperatures; at 100° C one part of water dissolves more than eleven parts of the nitrate; it is also soluble in alcohol and ether. Silver nitrate melts at 209° C and decomposes quantitatively above 320° C into silver nitrite, $AgNO_2$, and oxygen. When pure, it is not decomposed by light, but in the presence of organic matter blackening takes place. Either in the solid state or in solution it stains the skin black, and a dilute solution in ether is sometimes used as a hair-dye. The nitrate cannot be used as the basis of a marking-ink for linen, since the strong acid liberated when the silver is deposited would corrode the fabric, and hence silver salts of various weak organic acids are used for this purpose.

Silver sulphide, Ag_2S, found native in the minerals silver glance or argentite, is formed by direct union of its elements or by precipitating a silver solution with sulphuretted hydrogen. Silver sulphate, Ag_2SO_4, is produced by dissolving the metal in hot concentrated sulphuric acid, sulphur dioxide being given off; it can also be produced by adding strong sulphuric acid to a silver solution. It is a white crystalline substance sparingly soluble in water, but dissolving in ammonia to give $2NH_3,Ag_2SO_4$.

Silver selenide, Ag_2Se, occurs in nature in the double selenides naumannite, $PbSeAg_2Se$, and eukairite, Cu_2SeAg_2Se. Silver telluride, Ag_2Te, occurs in the mineral hessite. Fulminating silver, which must not be confused with silver fulminate, is a black, exceedingly explosive powder, first obtained by Berthollet in 1788 by the action of strong ammonia upon silver oxide. When dry it is exceedingly unstable, as merely touching it with a feather is sufficient to cause violent detonation. It is probably variable in composition as the formulae Ag_3N and $AgNH_2$ have been assigned to it by different observers. Silver fulminate, $Ag_2C_2N_2O_2$, produced by the action of alcohol on a solution of silver nitrate containing free nitric acid, forms a grey crystalline powder. Silver azide, AgN_3, the silver salt of hydrazoic acid, HN_3, is formed by precipitating a silver solution with a soluble azide or by the interaction of silver nitrate and hydrazine sulphate. It is a white curdy precipitate physically resembling silver chloride. The two last compounds are used as detonators for high explosives.

Silver cyanide, AgCN, formed by the addition of a soluble cyanide to a silver solution, is a white curdy precipitate, soluble in excess of alkali cyanide or in ammonia. On ignition it is decomposed into silver, cyanogen and paracyanogen, and can be thus distinguished from the chloride which it resembles in many respects. It is, however, not decomposed on exposure to light.

Certain silver salts yield stable co-ordinative compounds with ethylenethiocarbamide (etu), the complex chloride [Ag,3etu]Cl is readily soluble in water, and not affected by light; two complex nitrates are known, one sparingly soluble $[Ag_2,3etu](NO_3)_2$, and the other readily soluble $[Ag,4etu]NO_3$ (Morgan and Burstall, 1928).

Bivalent Silver.—In the foregoing silver salts the metal is invariably present in the univalent condition. A co-ordinative compound of bivalent silver has, however, been described by Barbieri, 1912; which has the constitution $[Ag, 4Py]S_2O_8$, that is argentic persulphate with four molecules of pyridine of crystallization; it is a sparingly soluble, yellow, crystalline substance.

Further evidence of the existence of complex derivatives of bivalent silver is furnished by W. Hieber and F. Mühlbauer (1928), who employ the organic diamine, *o*-phenanthroline (pha), in preparing the brown persulphate, $[Ag, 2pha]S_2O_8$, and also the perchlorate, chlorate, nitrate and acid sulphate, $[Ag, 2pha]X_2$, where $X=ClO_4$, ClO_3, NO_3 or HSO_4.

Medicinal Use.—Two compounds of silver are in the *British Pharmacopoeia:* (1) *Argenti nitras* (U.S.A. and British Pharmacopoeia), lunar caustic, incompatible with alkalis, chlorides, acids (except nitric and acetic), potassium iodide and arsenical solutions. From the nitrate are made (*a*) *argenti nitras indurata,* toughened caustic, containing 19 parts of silver nitrate and one of potassium nitrate fused together into cylindrical rods; (*b*) *argenti nitras mitigatus,* mitigated caustic, in which one part of silver nitrate and two parts of potassium nitrate are fused together into rods or cones.

(2) *Argenti oxidum,* incompatible with chlorides, organic substances, phenol, creosote, etc., with which it forms explosive compounds.

Therapeutics.—Externally the nitrate has a limited caustic action, destroying the superficial tissues and separating the part acted on as a slough. It may be employed to destroy warts or small growths and to reduce exuberant granulations, or it may be applied to bites. In granular lids and various forms of ophthalmia, solutions of silver nitrate (2 gr. to 1 fl.oz.) are employed. A 1% solution is also used as a prophylactic for ophthalmia neonatorum.

The effect of the nitrate being both astringent and stimulating as well as bactericidal, solutions of it are used to paint indolent ulcers, and in chronic pharyngitis or laryngitis. Silver salts are most useful as an injection in sub-acute and chronic gonorrhoea; one uses either the nitrate (1–5% solution) or protargol (1% solution), which is a proteid compound containing 8% of silver; they also benefit in leucorrhoea. In pruritus of the vulva and anus, a weak solution of silver nitrate will relieve the itching, and strong solutions painted round the base of an incipient boil will abort its formation.

Internally the nitrate has been used in the treatment of gastric ulcer, in ulcerated condition of the intestine, and in chronic dysentery. For intestinal conditions it must be either given in a keratin-coated pill or injected high up into the rectum. The oxide has been given in epilepsy and chorea. Nitrate of silver is eliminated from the system very slowly and the objection to its continuous use as a drug is that silver is deposited in the

tissues causing *argyria* or chronic silver poisoning, of which the most prominent symptom is the dark slate-blue colour of the lips, cheeks, gums and later of the skin. Taken in large doses, nitrate of silver is a powerful poison, causing violent abdominal pain, vomiting and diarrhoea, with the development of gastro-enteritis. In some cases nervous symptoms and delirium supervene. The treatment consists in the use of solutions of common salt, followed by copious draughts of milk or white of egg and water, or soap in water, in order to dilute the poison and thus to protect the mucous membranes of the oesophagus and stomach. (F. E. M.)

SILVER: METALLURGY, MINING AND PRODUCTION. Silver was discovered later than gold and copper, but has been known to man from prehistoric times. Silver ornaments and decorations have been found in the royal tombs of Chaldaea, built in the fourth millenium B.C. It was in use as money probably as early as gold, and it is recorded that Abraham paid Ephron in silver for land bought as a burial place. Silver is also mentioned as money in a Chaldaean inscription of about 4500 B.C., according to Gowland. In ancient Egypt it was scarce, and in the IV. and succeeding dynasties it was more valuable than gold, but in the XVIII. dynasty trade with the eastern Mediterranean countries made silver more plentiful and cheaper than gold.

Occurrence and Distribution.—Silver is sometimes found in the metallic state ("native silver") but unlike gold it is generally combined with other elements in its ores. Horn-silver, AgCl, and embolite (a chloro-bromide), found in the oxidized portions of lodes near the surface, have been formed by the weathering of more complex compounds. At deeper levels, silver usually occurs as sulphides, arsenides and antimonides (compounds of silver with sulphur, arsenic and antimony respectively). Native silver occurs in dendritic and wire-like forms which are aggregates of minute crystals, usually cubes and octahedra belonging to the cubic system. It also occurs in thin sheets and sometimes in masses. At Kongsberg in Norway, where the mines have been worked for centuries, large masses of native silver have been found, one of which weighed 697 kilogrammes or nearly three quarters of a ton. Native silver has been found, associated with other silver ores, at Cobalt, Canada, at Broken Hill, N.S.W., and in many localities in the United States, Mexico and South America, occurring for example in the native copper of Lake Superior, but it is not an important source of production of silver.

Argentite, Ag_2S, a soft black sulphide of silver, is one of the commonest ores of silver, but complex sulphides containing antimony and arsenic are also of frequent occurrence. The most important of these as sources of silver are Stephanite, $5Ag_2S$, Sb_2S_3, iron black in colour; the ruby-silver ores, Pyrargyrite or dark red silver ore, $3Ag_2S$, Sb_2S_3 and Proustite or light red silver ore, $3Ag_2S$, As_2S_3; Dyscrasite or antimonial silver, Ag_6Sb, and Polybasite. Grey copper ore or Fahlerz, a complex mineral containing copper, iron, zinc, antimony, arsenic and sulphur, is also an important silver ore of which no two specimens agree in composition. At Cobalt, Ontario, a large proportion of the ore taken from the mines in 1907 contained thousands of ounces of silver per ton, but such rich ores are unusual, and silver ores containing as much as ½% of silver or 150 oz. per ton are generally regarded as very rich. A large part of the world's production of silver is, however, not obtained from true silver minerals but from lead, copper and zinc ores in which it is an accidental constituent. These are called argentiferous ores. Galena (lead sulphide), in particular always contains silver, in amounts ranging as a rule from 20 oz. to 200 oz. per ton, which is extracted as a by-product at a trifling cost. One result of the large yield of silver in lead and copper smelting is that its market price has not such a strongly controlling influence on the amount of production as is observable in the statistics of other metals. The amounts of lead and copper ores smelted and of silver extracted from them depend mainly on the demand for lead and copper and their market prices and not on the price of silver. About 1½ million oz. of silver are extracted annually from gold bullion and the remainder is from ores obtained by mining in rock, as there is no silver obtained by washing loose alluvial deposits. For the operations of silver mining, see MINING, METALLIFEROUS.

Extraction of Silver from Ores.—The treatment of silver ores was for centuries chiefly by amalgamation (*q.v.*) but lixiviation processes, in which the silver is dissolved and the solutions washed out of the ore, were introduced in the middle of the 19th century and passed into wide use. In one group of these processes, much used for a time in the United States, the ore was roasted with common salt in rotating cylindrical or other furnaces in order to convert the silver into chloride of silver which was then dissolved by various solutions. These solutions had little or no effect on metallic silver or on silver sulphides or complex minerals containing silver. In the Augustin process the silver chloride was dissolved in hot strong brine (common salt). It was superseded by the Patera process, in which a solution of sodium thiosulphate (commonly called hyposulphite, the "hypo" of photography) was used. In the Kiss process the leaching solution contained calcium thiosulphate and in the Russell process a double thiosulphate of sodium and copper. These processes have been replaced by the cyanide process (*q.v.*), in which a preliminary roasting is not required, or by smelting. Smelting is merely the ordinary smelting of lead ores or copper ores which contain silver, but it is often found to be the more profitable course to add true silver ores to the smelting mixture, instead of treating them separately by the cyanide process. The increased percentage of extraction by smelting compensates for the additional cost, if adequate supplies of lead or copper ore and fuel are at hand. For lead and copper smelting and the extraction of silver from the products, see LEAD, COPPER.

Refining.—Crude silver, produced by the cyanide process, or separated from lead by cupellation, or from copper or gold by electrolysis, contains small amounts of copper, gold, bismuth, lead, and other metals. When it contains a few parts of gold per thousand it is called "doré silver." Doré silver was formerly refined by boiling in sulphuric acid (*see* GOLD MINING AND METALLURGY) but more recently most of it has been treated by electrolysis. Both the Moebius and Balbach processes are used. Besides doré silver, scrap and residues of all kinds containing gold up to about one third of the total weight may be treated by electrolysis.

In the Moebius process the silver is cast into plates about 18in. long, 10in. wide and ½in. thick. Each plate is enclosed in a linen or cotton bag and a number of them are suspended in a parallel series in earthenware or porcelain vats. The plates form the anodes of an electric circuit and are supported by hooks from rods connected at one end with the positive pole of a dynamo. Cathode plates consisting of thin rolled sheets of pure silver are suspended in the vats alternately with the anodes, parallel to them and about 1¾in. distant. The electrolyte filling the vats consists of a solution containing ½–1% of silver nitrate and 1–2% of nitric acid. A current of electricity is passed from the anodes to the cathodes through the liquid, which is kept stirred. The silver, copper and some other metals are dissolved from the anodes, and pure silver is deposited on the cathodes in pulverulent and non-coherent form. The cathodes are continually cleaned by wooden scrapers moving backwards and forwards automatically and by this means are kept free from loose crystals of silver. If left undisturbed the crystals form trees which may stretch from cathode to anode and cause short circuits. The detached silver falls into canvas trays at the bottom of the tanks. In later practice glue or gelatine is added to the solution and the stirring is more vigorous, with the result that hard, compact, adherent deposits of silver are formed on the cathodes. In one form of apparatus there are rotating cylindrical cathodes, surrounded by anodes, in order to enable stronger currents to be used with more expeditious deposition.

The copper accumulates in the solution as copper nitrate and, to prevent it from being deposited on the cathodes with the silver, more nitric acid is added and the current is reduced. When the amount of copper in the liquid reaches about 5%, part of the solution is withdrawn and replaced by fresh solution of silver nitrate; otherwise copper would be deposited on the cathodes. The deposited silver is removed, washed, melted and cast into ingots which should contain over 99·9% of pure metal. The slime in the anode bags consists in great part of gold which remains undis-

solved. In the Balbach cell, the whole bottom surface of an earthenware trough is the cathode which may consist of carbon. The anodes are placed horizontally above it and are supported on perforated earthenware trays or a grill consisting of wooden rods. The trays are covered with a filter cloth to prevent the anode slime from falling through and settling on the cathode.

Alloys of Silver.—The addition of a small percentage of copper to silver lowers its melting point, prevents it from "sprouting" on solidification, and makes it harder, without sensibly impairing its malleability, altering its colour, or preventing it from taking a high polish; thus, silver-copper alloys are used for silver coin and plate. A little cadmium is often added to them to facilitate the manufacture of wares, and other metals such as antimony have been added to produce alloys which will not tarnish. The colour of silver-copper alloys remains nearly white until the copper amounts to about 45% to 50% when the alloy is pale red and as the copper is increased further the colour becomes deeper. Silver-copper alloys, like pure silver, blacken in the atmosphere of towns, from the formation of a film of sulphide of silver. They blacken also when heated to redness but the black oxide of copper thus formed can be removed from their surface by warm dilute sulphuric acid. Silver alloys with molten lead with great readiness and in all proportions, but if the melted alloy is cooled, pure lead crystallizes out and sinks in the liquid which becomes enriched until it contains 2·5% of silver, when the alloy solidifies as a whole. These properties are used in the Pattinson process (*see* LEAD). Zinc removes silver from molten lead, forming a zinc-silver compound which is lighter than lead and floats to the top with the dross and surplus zinc so that it can be skimmed off, as in Parke's process of desilverizing lead. (*See* LEAD.)

Silver is at once "wetted" by mercury when brought into contact with it at the ordinary temperature (*see* AMALGAMATION) but the interpenetration of the metals is exceedingly slow and a true solid amalgam is difficult to form. The crystalline amalgam containing 35% of silver and 65% of mercury is produced in the beautiful branching form known as *Arbor Dianae* by prolonged contact between mercury and a solution of silver and mercury nitrates. The other alloys of silver are of no industrial importance.

Production.—The most ancient silver mines of importance known to history were those in Asia Minor and on islands in the Aegean Sea. The deposits of silver-lead ore at Hissarlik in the Troad were worked probably as early as 2500 B.C. and lasted for many centuries, and the Greek mines at Laurium, also of silver-lead, were known in 1000 B.C. The Romans obtained most of their silver from Spain, but in the middle ages the supplies which had previously been plentiful became scarce, as production was small and the stocks gradually disappeared. The scarcity came to an end with the discovery of America, which has given the rest of the world a large and ever increasing supply of silver. The following estimates of production are those given in the *Annual Reports of the Director of the United States Mint.* The statistics for the period 1493–1885 were compiled by Dr. Adolf Soetbeer, and from 1886 onward the estimates were made by the United States Mint. Between 1493 and 1520 the average annual production of the world was 1,511,000 oz. troy of fine silver. The output then rose until in 1545–60 the annual average was 10,018,000 oz., but a lull followed up to about the year 1700, during which production was almost stationary. In the period 1701–10 the average was 11,432,500 oz. per annum and the production then rose gradually until in 1801–10 it was 28,747,000 oz. per annum. The Wars of Independence of the Spanish colonies of America disorganized the mining industry, and production fell so that in 1821–30 the average was only 14,807,000 oz. Thereafter the rise was almost continuous until in 1900 it was 173,591,000 oz.

The annual production of the world from mines since 1901 is given below in units of 1,000 oz. fine.

1901	173,011	1908	203,131
1902	162,763	1909	212,149
1903	167,689	1910	221,716
1904	164,195	1911	226,193
1905	172,318	1912	230,904
1906	165,054	1913	210,013
1907	184,207	1914	172,264
1915	173,000	1921	171,286
1916	180,802	1922	209,815
1917	186,125	1923	246,010
1918	203,159	1924	239,485
1919	179,850	1925	245,214
1920	174,420	1926	253,587

About two-thirds of the world's supply is derived from Mexico and the United States. The Mexican mines first sent supplies to Europe in the 16th century and during the years 1781–1800 yielded two-thirds of the world's production. After a period of less activity owing to civil war, Mexico was again the leading producer in 1924–27. The United States became a large producer about 1860, and was first among the countries during most of the next 40 years. Its production was 116,019 oz. in 1860; 1,546,920 oz. in 1861; 22,254,002 oz. in 1872 and 54,647,000 oz. in 1900, but the production is no longer increasing. Canada produced little until late in the 19th century, but South America has sent supplies to Europe since the discovery of the Potosi mines in Peru in 1533. In Europe, Germany and Spain are the most important producers. The German mines were worked in the 10th century and at the beginning of the 16th century the production was over 400,000 oz. annually. In 1905 the output was 12,535,238 oz. but declined later. In Spain the mines were neglected in the 16th century owing to the plentiful supplies from America, but production was revived in the 19th century. The output in Asia is chiefly from India and Japan. Australia became noticeable after the discoveries at Broken Hill, New South Wales, where 36,608 oz. were produced in 1885 and 7,727,877 oz. in 1890. The silver in Africa is mainly derived from the gold bullion of the Transvaal.

The production by countries is given in the *Report* of the director of the *United States Mint* for 1927 as follows, in units of 1,000 oz. fine.

	1925	1926
UNITED STATES	66,107	62,673
CANADA	20,229	22,372
MEXICO	92,885	98,291
CENTRAL AMERICA / WEST INDIES	2,701	3,499
SOUTH AMERICA	30,343	30,340
PERU	(19,917)	(21,500)
BOLIVIA	(4,347)	(5,834)
CHILE	(3,202)	(2,877)
EUROPE	11,064	11,499
GERMANY	(4,780)	(5,359)
SPAIN	(3,394)	(3,000)
GREAT BRITAIN	(32)	(41)
ASIA	12,337	12,510
INDIA	(4,855)	(5,125)
JAPAN	(4,835)	(4,776)
AUSTRALIA	10,841	11,200
NEW SOUTH WALES	(9,220)	(9,710)
AFRICA	1,419	1,202
TOTAL FOR THE WORLD	245,814	253,587

The silver produced in the world is in great part exported to India and China. The net amounts sent to these countries, taken together, averaged about 87,000,000 oz. per annum in the years 1910–24 according to the figures published by the London dealers in bullion. *The Report of the Director of the United States Mint* gives the following figures of coinages and consumption in the industries for the world.

	1925 oz. fine	1926 oz. fine
SILVER COINAGE	188,306,076	148,055,068
COINS WITHDRAWN	84,737,192	43,827,862
NET COINAGE	103,568,884	104,227,206
INDUSTRIAL CONSUMPTION (excluding the EAST)		
UNITED STATES	39,827,000	39,408,000
FRANCE	10,750,000	10,224,000
GREAT BRITAIN	8,500,000	8,000,000
OTHER COUNTRIES (incomplete)	8,513,000	6,701,000
TOTAL	67,590,000	64,333,000

BIBLIOGRAPHY.—W. Gowland, "Silver in Roman and Earlier Times" *Archaeologia*, vol. 69, p. 121 (1918), is a complete account for archaeologists; John Percy, *Silver and Gold* (1880), contains a full descrip-

tion of the ores of silver; C. A. Stetefeldt, *Lixiviation of Silver Ores* (1890) is a technical work; W. Gowland, *Metallurgy of the Non-Ferrous Metals* (1914) contains a technical account of the metallurgy of silver; *see* also *Annual Reports of the Director of the Mint* (Washington, 1880, foll.); and B. White, *Silver: Its History and Romance* (1917), a popular treatise. (T. K. R.)

SILVER-BERRY (*Elaeagnus argentea*), a North American shrub of the oleaster family (Elaeagnaceae), found from Quebec to Hudson bay and British Columbia, south to Minnesota and Utah. It grows from 6 to 12 ft. high, with silvery-scurfy leaves and numerous fragrant flowers, pale yellow within and silvery without, borne in the leaf-axils, and round-ovoid, olive-like silvery fruit, with a mealy edible fleshy portion enclosing a grooved nut.

SILVER CITY, a town of south-western New Mexico, U.S.A., in the foothills of the Mogollon mountains, at an altitude of 6,000 ft.; the county seat of Grant county. It is on Federal highway 180 and the Santa Fe railway. Pop. (1930) 3,519. It is in a metal-mining (copper, iron and manganese) and stock-raising region and a health resort, the gateway to the Gila National Forest. Silver City was founded in 1870 on the discovery of rich deposits of silver ore that could be reduced in a mud furnace and had a wild boom period. It was the first town incorporated in New Mexico (1878).

SILVERFISH, a small active wingless insect, so called from the silvery glitter of the scales covering the body. It is less than half an inch long and is found in damp corners or amongst books and papers in houses. Although accredited with destroying paper and linen, it probably feeds only on farinaceous or saccharine substances. Scientifically it is *Lepisma saccharina* and belongs to the order Thysanura, sub-class Apterygota (*q.v.*).

SILVERIUS, pope from June 536 to March 537, successor of Pope Agapetus I., was a legitimate son of Pope Hormisdas, born before his father entered the priesthood. He was consecrated on June 8, 536, having purchased his elevation from the Gothic king Theodotus. Six months afterwards (Dec. 9) he was one of those who admitted Belisarius into the city. He opposed the restoration of the patriarch Anthimus, whom Agapetus had deposed, and thus brought upon himself the hatred of Theodora, who desired to see Vigilius made pope. He was deposed by Belisarius in March 537 on a charge of treasonable correspondence with the Goths, and degraded to the rank of monk. He went to Constantinople, and Justinian, who entertained his complaint, sent him back to Rome, but Vigilius was ultimately able to banish his rival to Pandataria, where the rest of his life was spent.

SILVER-PLATED WARE: *see* ELECTRO-PLATE MANUFACTURES.

SILVERSMITHS' AND GOLDSMITHS' WORK. Personal ornaments, utensils, vases, decorative objects, etc., made of silver or gold, with their various alloys, are generally known as silversmiths' and goldsmiths' work. The article that follows is treated historically under the following divisions: *Egyptian to Roman*, with *Jewellery* included in a separate section; *European; North and South America; Oriental Work*. (*See* also EGYPT; ART AND ARCHAEOLOGY; INDIAN AND SINHALESE ART AND ARCHAEOLOGY; ROMAN ART; BYZANTINE ART; BRONZE; IRON IN ART; DRINKING VESSELS; JEWELLERY.)

EGYPTIAN TO ROMAN

Gold, silver and their natural or artificial mixture called electrum or white gold, were worked in ancient Greece and Italy for personal ornaments, for vessels, arrows and weapons, for coinage, and for inlaid and plated decoration of baser metals. Pliny notes that gold is generally found mixed with silver, and says that when the proportion of silver amounted to one-fifth the alloy was called electrum. The source of native electrum was the river Pactolus in Lydia, whose golden sands supplied the fabulous wealth of Croesus. Aegean lands were rich in precious metals. The considerable deposits of treasure found in the earliest prehistoric strata on the site of Troy are generally assigned to the second city; they are earlier than the sixth ("Homeric") city, and are not likely to be later than 2000 B.C. The largest of them, the so-called Treasure of Priam, is a representative collection of jewels and plate. The gold ornaments were packed in a large silver cup. They consist of elaborate diadems or pectorals, six bracelets, 60 earrings or hair-rings, and nearly 9,000 beads. The Trojan vases have bold and simple forms, mostly without ornament, but some are lightly fluted. Many are wrought from single sheets of metal. The characteristic handle is a heavy rolled loop soldered or rivetted to the body. Some silver flasks with inverted cup-covers have small shoulder-studs pierced vertically for hanging. Bases are sometimes round or pointed, sometimes fitted with separate collars, but more often slightly cupped to make a low ring-foot. An odd shape in gold is an oval bowl or cup with a broad lip at each end and two large roll-handles in the middle. The oval body has Sumerian affinities, and it seems likely that Trojan arts at this time were Asiatic rather than European. Asiatic influence had indeed invaded Europe, for the oval shape occurs in the contemporary pottery of the Greek mainland and islands (Helladic and Cycladic). A plain spouted bowl of usual early Helladic shape in the Louvre is the typical specimen of goldsmith's work from pre-Mycenaean Greece, and the scarcity of precious metals points to lack of wealth as prime cause of the artistic backwardness of these regions. Silver seems to have been more plentiful in the Cyclades, but only a few simple vessels, head-bands, pins and rings survive. Conditions were different in Crete.

Minoan and Mycenaean.—A profusion of gold jewellery was found in early Minoan burials at Mochlos, three silver dagger-blades come from a communal tomb at Kumasa, and silver seals and ornaments of the same age are not uncommon. An elegant silver cup from Gournia belongs to the next epoch (Middle Minoan I., *c.* 2000 B.C.); it is unique, but numerous imitations of its cusped and carinated form in clay, and of its metallic sheen in glazed and painted decoration, prove that such vessels were common. Minoan plate and jewellery are amply represented in the wealth of the mainland tombs at Mycenae and Vaphio. The vases from Mycenae are made indifferently of silver, gold and bronze; but gold is generally reserved for drinking-cups, small phials and boxes; silver is used for jugs as well. Much of the funeral furniture is gold, notably the masks that hid the faces or adorned the coffins of the dead. It has been thought that the small gold discs, which Schliemann found in prodigious quantities (700 in one grave), were nailed on wooden coffins, but they may have been sewn on clothes. They are impressed with geometrical designs based on circular and spiral figures, stars and rosettes and natural forms such as leaves, butterflies and octopods. Smaller bossed discs bearing similar patterns may be button-covers. Models of shrines and other amulets are also made of gold. A splendid piece of plate is a silver counterpart of the black steatite libation-vase from Knossos in the form of a bull's head, with gold horns, a gold rosette on the forehead, gold-plated muzzle, ears and eyes. The gold here and in other Mycenaean plating is not laid on the silver, but on inserted copper strips. The gold cups from Mycenae are of two main types: plain curved or carinated forms related to the silverware and pottery of Troy, and embossed conical vessels of the Minoan tradition. Some of the plain pieces have handles ending in animals' heads, which bite the rim or peer into the cup. The embossed ornament consists of vertical and horizontal bands of rosettes and spiral coils, floral, foliate, marine and animal figures. The designs are beaten through the walls and are consequently visible on the insides of the vessels; but the finest examples of their class, the two gold cups from the Vaphio tomb near Sparta, have a plain gold lining which overlaps the embossed sides at the lip. The reliefs on the Vaphio cups represent men handling wild and domesticated cattle among trees in a rocky landscape. The handles show the typical Minoan form: two horizontal plates rivetted to the body at one end and joined at the other by a vertical cylinder. Steatite vases carved with similar pictorial reliefs were evidently made to imitate embossed gold. A fragment found at Palaikastro had part of its original plating attached.

Cretan and mainland tombs have produced many examples of weapons adorned with gold. Modest ornaments are gold caps on the rivets joining hilt and blade, but the whole hilt is often cased in gold. An example from Mycenae has a cylindrical grip of openwork gold flowers with lapis-lazuli in their petals and crystal

EXAMPLES OF THE GOLDSMITH'S ART BY BENVENUTO CELLINI

Above: Gold and enamel cup, known as the Rospigliosi cup, by Benvenuto Cellini (1500–71), metal-worker and sculptor of the Florentine school, at the height of the Italian Renaissance. The cup is now in the Metropolitan Museum of Art, New York

Below: Golden salt-cellar, wrought by Cellini for Francis I. of France, who was his patron during his exile in that country. Now in the Museum of Vienna

filling between them; the guard is formed by similarly inlaid dragons. The most splendid Mycenaean blades are bronze inlaid with gold, electrum, silver and niello. Here again the work is done on inserted copper plates. This kind of flat inlay seems to have been originally Egyptian. It occurs on daggers from the tomb of Queen Aah-Hotep, which are contemporary with the Mycenaean (*c.* 1600 B.C.), and it is significant that two of the Mycenae designs have Egyptian subjects, though their style is purely Minoan. These are the scenes of cats hunting ducks among papyrus-clumps beside a river in which fish are swimming. Another blade bears Minoan warriors fighting lions, and lions chasing deer. A dagger from Thera has inlaid axe-heads; one from Argos, dolphins; and fragments from the Vaphio tomb show men swimming among flying-fish. These are masterpieces of Minoan craftsmanship; in the long decadence of the Mycenaean age there seems to have been no invention, and later pieces of goldsmith's work repeat conventional forms and ornaments.

Greek and Etruscan.—The period of transition from the Bronze to the Iron Age, when Aegean external relations were violently interrupted, was not favourable either to wealth or art, and the only considerable pieces of plate that have come from Greece are the embossed and engraved silver bowls made by Phoenicians. Most of them bear elaborate pictorial designs of Egyptian or Assyrian character, and are evidently foreign to Greece; but some simpler types, decorated with rows of animals in relief or wrought in the shape of conventional flower-bowls, can hardly be distinguished from the first Hellenic products. Early Greek work is rare. A severe and elegant silver bowl in the Metropolitan Museum, New York, represents the flower-type in its finest style. It is cast and chased, and probably belongs to the 5th century B.C. Other pieces of the same age are simply moulded, and no special kind of decoration seems to have been developed for work in precious metals.

Silver vases and toilet instruments have been found beside the commoner bronze in Etruscan tombs. A chased powder-box of the 4th century is in the Metropolitan Museum, New York. The bronze reliefs of the archaic chariot in the same collection have their opulent counterparts in some hammered silver and electrum fragments in London, Munich and Perugia. The electrum details are attached with rivets.

Roman.—About the 4th century B.C. there was revived the fashion of ornamenting silver vessels with relief, and this type of work, elaborated in the Hellenistic age and particularly at Antioch and Alexandria, remained the usual mode of decoration until the end of the Roman empire. Various fabrics of moulded pottery correspond to the successive styles of metalware. A silver vase in the British Museum, bearing a frieze of chariots between floral bands, is nearly a reflex of an earthenware Calene bowl (3rd century B.C.) in the same collection. Pliny names Greek silversmiths whose work was valued highly at Rome, and laments the disappearance of the art in his own day. He must refer only to its quality, for Roman silverware has been abundantly preserved. Many rich hoards in modern collections were buried by design during the calamitous last centuries of the ancient world, and the most sumptuous, the Boscoreale treasure, was accidentally saved by the same volcanic catastrophe that destroyed Herculaneum and killed Pliny. This treasure (108 pieces) is mostly in the Louvre. A hardly inferior hoard (70 pieces) found at Hildesheim and now in the museum of Berlin, also belongs to the early empire. The acquisition and appreciation of silver plate was a sort of cult at Rome. Technical names for various kinds of reliefs were in common use (*emblemata, sigilla, crustae*), weights were recorded and compared and ostentatiously exaggerated. Large quantities of bullion came to Rome with the spoils of Greece and Asia in the 2nd century B.C., and Pliny says that even in republican times there were more than 150 silver dishes in the city of a hundredweight apiece. The Emperor Claudius had a slave who possessed a five-hundredweight dish. Weights of vessels are often marked on their bases.

Cups and jugs of Augustan style are usually covered with ornament in high relief. The subjects are very diverse: historical, mythological and mystic scenes, formal and naturalistic designs of flowers and foliage, graceful studies of animals and birds. Others have conventional fluting, petals or gadroons, Bacchic instruments and masks, embossed or engraved wreaths, gilt or inlaid with niello. Silver and niello inlay was commonly applied to bronze plates. A singular type of silver bowl (*patera clipeata*) has a central ornament in high relief or even in the round: portrait-busts are not uncommon in this place. In course of time the ornament was restricted, and later Roman plate is largely plain with narrow border-friezes, small central medallions, and handles embossed in low relief. One of the very few gold pieces that survive, a shallow bowl found at Rennes and now in the Bibliothèque Nationale of Paris, is exceedingly elaborate. It measures 25 centimetres across and weighs 1,315 grammes. The central medallion and its surrounding frieze contain scenes of a bibulous contest between Bacchus and Hercules; between these and the edge is a row of 16 gold coins each framed in a foliate wreath. The coins range from Hadrian to Caracalla. In the same collection are several examples of very large silver plates (*clipei* or *missoria*), in which the whole field is embossed with mythological or historical subjects. The largest (called the shield of Scipio) is 72 centimetres in diameter and weighs 10,300 grammes. Another bears the name of Gelimer, king of the Vandals and Alans (6th century). The "shield of Theodosius" at Madrid shows the emperor, seated between Valentinian and Arcadius among his guards, with an allegorical group in the exergue. The persistence of classical and even pagan subjects in early Christian work is well illustrated by the silver and gilt casket of Projecta, the centrepiece of the Esquiline treasure in the British Museum. It was a wedding-present; some of its many panels contain incidents in the marriage ceremony, others have groups of Venus and her attendants, and the lid bears the pious exhortation: *Secunde et Proiecta vivatis in Christo.*

Jewellery.—There is not the same break between prehistoric and classical jewellery as between other gold and silverwork and arts in general. It is true that certain types of ornament went out of fashion at various times and places, but the ancient jeweller's craft seems to have been rather cosmopolitan, and designs of common articles, earrings, bracelets and necklaces, were universal and persistent. The outstanding feature of ancient jewellery is its large display of figured surface, generally resulting in a tinsel fabric. The earliest specimens of Aegean jewels come from opposite ends of that region, Troy and Crete, and are contemporary (*c.* 2500 B.C.). The Trojan are the more elaborate but the elements are the same in both: thin wire in linked and plaited chains and coils, thin foil in petals and rosettes. The largest Trojan diadem or pectoral is made of 90 gold chains fringed with tiny scales and supporting foil-pendants. The simplest earrings are swelling hoops, simple or multiple or enriched with transverse bands. They are identical with archaic Greek types 2,000 years later. A more elaborate earring is a horizontal half-cylinder made of wire or plate with rosettes along its front upper edge and pendent discs below. This also reappears in the archaic period as the basket-earring of Etruria, doubtless an Ionian importation. Pinheads and bracelets are decorated with applied rosettes and spiral coils, and the pins are crowned with rows of little jugs. A plaited wire bracelet at Troy is reflected in a foil bracelet stamped with the same pattern at Mochlos in Crete.

This Early Minoan group contains many flower-headed pins, related on the one side to Trojan decorative rosettes, on the other to Sumerian hair ornaments. Granulation occurs on Trojan earrings, and was doubtless used at the same time in Crete, but very little jewellery has been found there, and earrings are scantily represented even in the wealth of the Mycenae shaft-graves. The swelling hoop was Mycenaean, and often had a pendent globule-cluster, which was ultimately enlarged into the semblance of a bull's head with granulated muzzle and coiled wire ears. The shaft-grave jewels are mostly diadems and hairpins, bracelets and pectorals, bead-necklaces and pendants, signet and finger-rings and plaques for decorating clothes. Thin plates cut and embossed in animal and floral forms served for all these ornaments. They are very seldom cast or wrought. Stone inlay is rare, but stone

beads are often mounted in gold, and enamel is not uncommon. European and oriental (Phoenician) elements are combined in a treasure from Aegina, now in the British Museum, which belongs to the very end of the Mycenaean age, *c.* 1000 B.C. Its designs are mainly stylized openwork figures fringed with small pendants.

In the following period diadems, bracelets and earrings were decorated by the old processes of stamping, granulation and enamelling in the new Geometric style. Archaic Greek and Italian jewellery (700–500 B.C.) was almost wholly oriental in design, Egyptian and Assyrian models of Phoenician introduction being reinforced by rich Ionian and Lydian wares. New forms in Greece and Etruria were the coiled bracelets and earrings ending in heads of lions and bulls, pomegranate, lotus and palmette pendants, winged figures of sphinxes and sirens and masks of satyrs. But the technique was unchanged. Embossed plates are the basis of the work, stamped with separate punches or hammered into dies, and finished singly or joined back to back around a plaster core. Granulation was brought to an amazing fineness, particularly in Etruria. Patterns were precisely drawn in a field of minute grains, which were fused into globules and soldered to their background in one operation. In Greek 5th century work granulation is displaced by filigree, and enamel reappears. The style of this and the next century aims at elegance and delicacy. Necklaces consist of pendent flowers and tassels in a trellis of finely plaited ropes; flower-petals are variegated with enamel. Hoops of earrings are masked with filigreed rosettes and discs, and support elaborate pendants. Victories, Cupids and doves were favoured here by Hellenistic sentiment, and a strange but quite popular Graeco-Roman type was made with pendent vases. A change of fashion at this time, doubtless under oriental influence, introduced large coloured stones, at first garnets, in the centres of designs, and the new decorative principle became dominant in Roman jewellery. The stones are cut in simple shapes and grouped in rows by colour, blue, red, green, sapphire, garnet, plasma, with pearl borders. They are usually plain, but sometimes engraved as cameos or intaglios. In the closing period, from the 3rd century A.D., gold coins of contemporary and earlier emperors were also set like gems, and the goldsmith's skill was mainly exercised upon the borders and backgrounds. These bear arcaded patterns in chased relief and open-work, a bold and heavy style which, with colour-decoration, ousted the classical figure-work, and gave its character to the jewellery of mediaeval Europe.

EUROPEAN

During the first six centuries there existed two principal sources of production of early Christian silver vessels: the Hellenistic and the Persian. The designs consisted often of figure compositions. Antioch was an important centre for goldsmiths' work after the 4th century, and here was made, in the 4th or 5th century, the "Antioch" chalice, now privately owned in New York City. From the 10th century, church vessels, especially chalices, became more sumptuous and were occasionally enriched with enamel and gems. Among extant early silver is the Esquiline treasure, Hellenistic in character, and the Lampsacus treasure, both in the British Museum; and the sacred treasure of Luxor, 5th to 6th centuries, now at Cairo. In the Metropolitan Museum at New York is the 6th century treasure from Cyprus, probably part of the same "find" as the objects at Nicosia and in the British Museum.

Byzantine silver of the 6th century is often marked with stamps in the manner of modern plate. St. Mark's in Venice contains many precious examples of Byzantine goldsmiths' work, including the famous *pala d'oro,* fashioned in Constantinople in 976, and enlarged and modified later by Venetian and other goldsmiths. The monasteries of Mt. Athos are rich in early vessels.

Early goldsmiths' work of a sacred character comprises the 6th century gold cross of Justin II. and Sophia, in St. Peter's, Rome; three great altar-frontals; (*a*) that executed before 835 in S. Ambrogio, Milan; (*b*) that in Aix-la-Chapelle cathedral; (*c.* 1000); and (*c*) that in the Cluny museum, Paris. To these may be added the *Codex Aureus,* and the ciborium of the Emperor Arnoulf, both at Munich. Early figures of the Virgin are two of the 11th century (with later additions) in Essen cathedral and another by a goldsmith of Hildesheim. The celebrated treatise of *c.* 1100 by the monk Theophilus, of Essen, is of extraordinary interest in the history of metal working.

A highly-skilled school of metal workers and enamellers was established in the 12th and early 13th centuries on the Meuse, chief of whom was Nicholas of Verdun. By his pupil or follower, Hugo d'Oignies, are three authenticated works, including his masterpiece, the shrine of St. Eleutherius (1247) in Tournai cathedral (see *Burlington Magazine,* xxxv.; xxxix.). By Siegfroid, pupil of Nicholas of Verdun, is a superb chalice of *c.* 1230, in Borgå church, Finland. Of the same school was Godefroid de Claire, goldsmith and enameller, of Huy.

English ecclesiastical work suffered incredible destruction at the Reformation. Of the few English silver chalices one of the earliest is that of the 13th century in the British Museum. Patens are more common. Important works are William of Wykeham's crozier at Oxford, and a censer and incense boat of *c.* 1350 in the Victoria and Albert Museum.

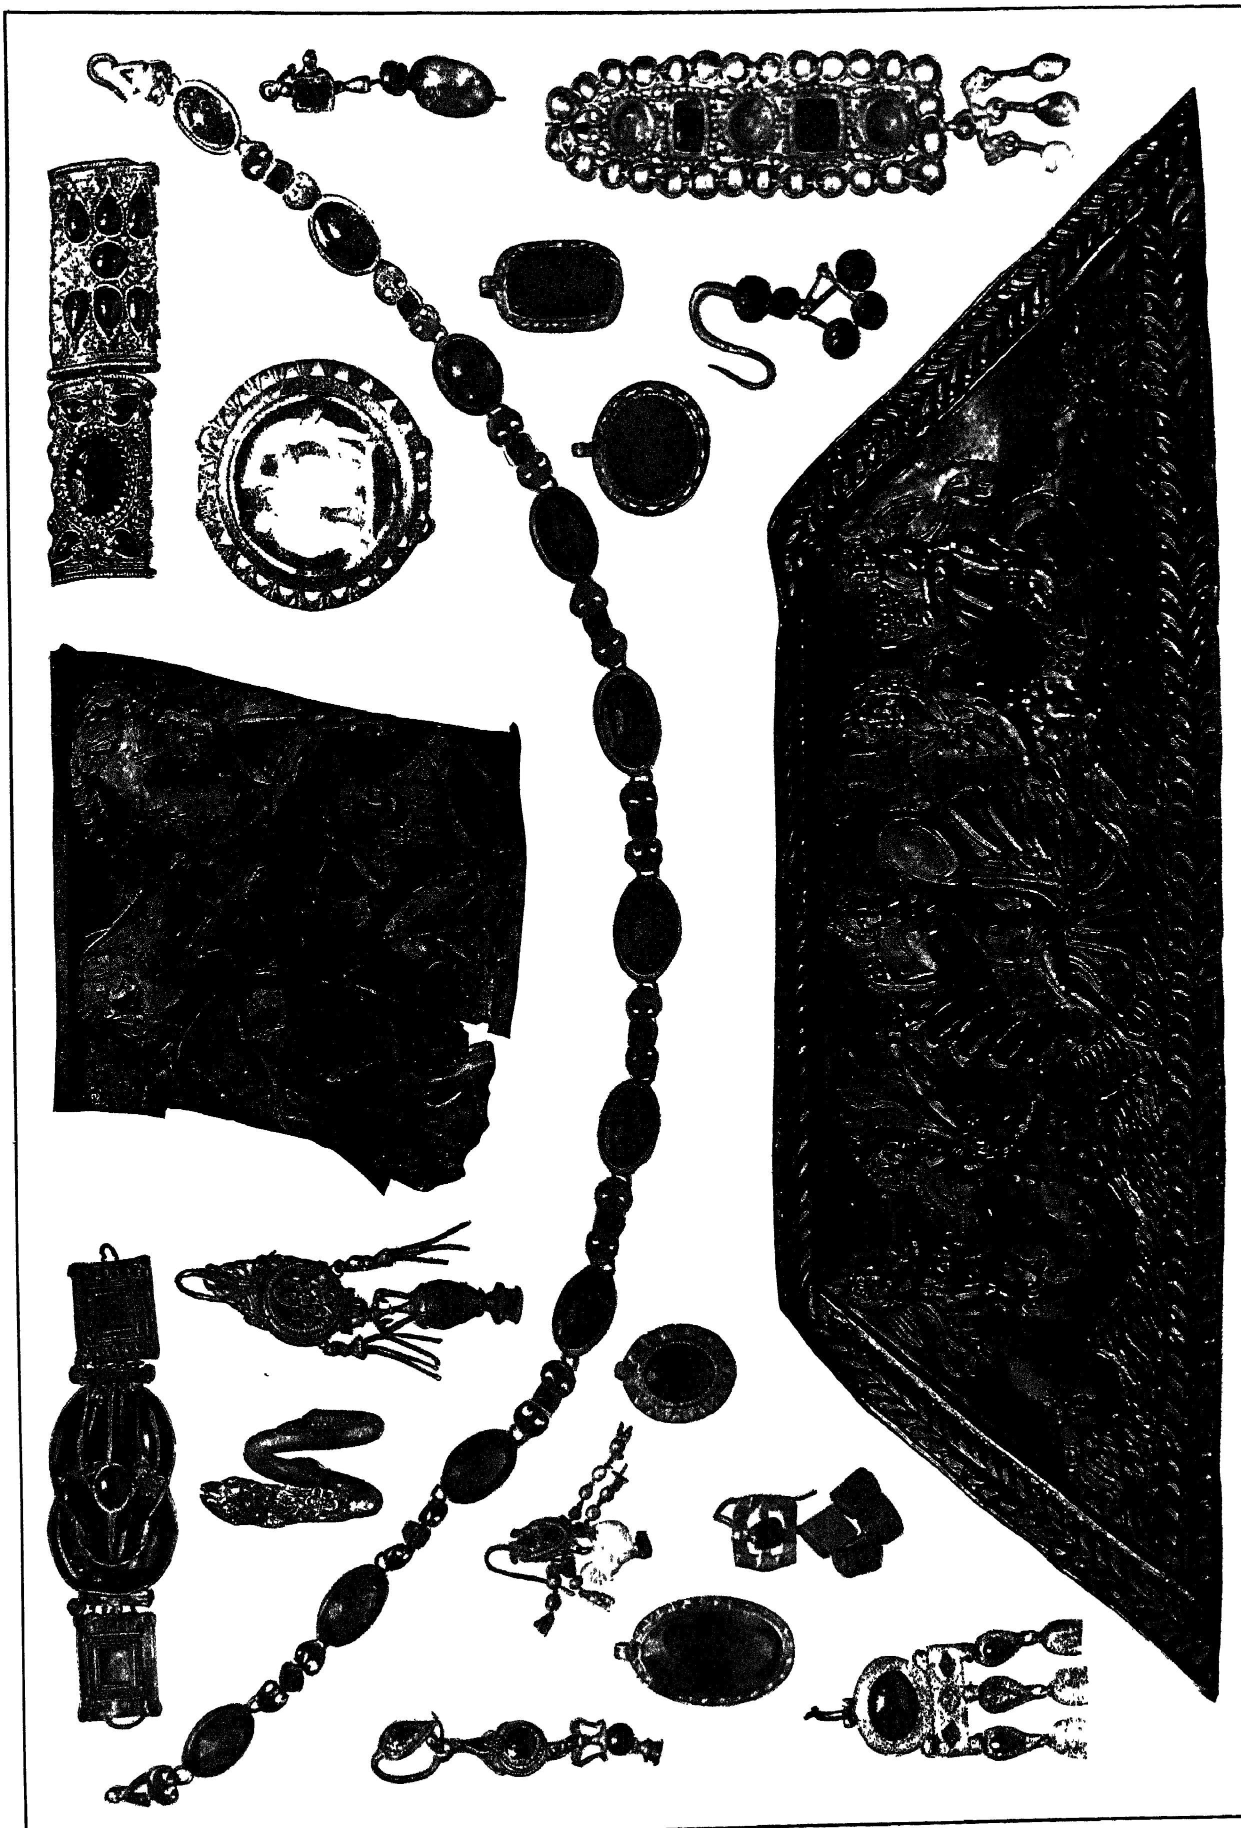
The early examples of ecclesiastical work in France include the Gourdon gold chalice and paten of the 7th century; a 9th century casket and a 10th century statuette of St. Foy, at Conques; the cross of Laon, in the Louvre (*c.* 1200); an early 13th century ciborium in Sens cathedral; a cross of the same century in Amiens cathedral; the Virgin of the abbey of Roncevaux, 14th century; and the Virgin in the Louvre (1339).

The churches of Italy abound in sacred vessels, especially from the 14th century, the early works including the 12th century altar-frontal at Città di Castello; and the chalice of 1290 by Duccio of Siena. Famous among reliquaries is the bust of St. Agatha at Catania, by Giovanni Bartolo, of Siena (1376). But more celebrated is the great reliquary of Orvieto, containing the blood-stained corporal of the Bolsena miracle, by Ugolino da Siena (*c.* 1338). Crosses include that of S. Giovanni, Florence, 1459, important for its influence upon others. Two great altar-frontals are in the cathedral of Pistoia and in S. Giovanni at Florence. Upon the latter were employed several famous artists—Antonio Pollaiuolo, Michelozzo, Verrocchio and others. The Abruzzi's greatest goldsmith, Nicola da Guardiagreli, designed the altar-frontal of Teramo (1433–48). An example of the combination of niello, enamel and silver, is the celebrated pax by Maso Finiguerra at Florence (1452). The most celebrated work of Valerio Belli (1468–1546), carver of crystal and medallist, is the crystal casket of 1532 in the Pitti palace, Florence. Caradosso, famous as a goldsmith and medallist, was the maker of a gem-set golden tiara for Julius II., known from an old coloured drawing in the British Museum, with a drawing of the gold morse executed by Cellini for Clement VII.

The early goldsmiths' work of Spain was of considerable importance. The Cross of the Angels, made in Asturias in the time of Alfonso II., and the Cross of Victory (908), both at Oviedo, are well-known. Chalices and other sacred vessels of unsurpassed richness were made in the Gothic and Renaissance periods. Under the sway of three members of the Arfe family in the 16th century several cathedrals were enriched with costly custodias (monstrances), great tower-like structures peculiar to Spain.

Early chalices were of two types with or without two handles; both lasted until the 13th century, when the two-handled form would seem to have been no longer made. The goldsmiths of the Merovingian period (420–751) were highly skilled and produced great quantities of jewellery and plate. The Carolingian period (768–814) brought a new style into the West. It used figure subjects in relief and foliated ornament, adopted from the Christian East through Italy.

Spoons are among the earliest things in silver. The Romans and Anglo-Saxons had their spoons. The earliest extant English spoon is probably the celebrated anointing spoon of the late 12th



ETRUSCAN, GREEK, HELLENISTIC AND ROMAN ORNAMENTS DATING FROM 6TH CENTURY B.C. TO A.D. 400

Greek buckle, in upper left, and beneath it an earring of gold decorated with enamel and stones of about 400 B.C. Beneath third jewel in the necklace, a Hellenistic earring of about 200 B.C.
In upper centre an Etruscan silver and gold relief with electrum plating, from Perugia. Said to be Ionic work of the 6th century B.C. In lower centre is the front panel of the lid of Projecta's bridal casket; early christian
All other objects are Roman necklace, earrings, beads and pendants, A.D. 100 to 400

or early 13th century, which was, however, re-fashioned in 1660. Early English spoons include the "Apostle" spoon, popular for 200 years from about 1450. Original sets of 13 are extremely rare, the first being dated 1536–37, and was acquired by the late J. Pierpont Morgan. Next in popularity was the seal-top spoon, made between *c.* 1510 and 1670. From about 1670 spoons in England became more common, and the patterns were copied by American silversmiths. Continental spoons are usually more ornate and are of many patterns from the 17th century. A typical German object in silver (and occasionally of gold) is a spoon, fork and toothpick combined, of the 16th and 17th centuries.

Forks of silver are rare until the 18th century. The earliest known English fork is dated 1632–33.

English Work.—In the early centuries, after the invasion of Britain, Anglo-Saxon ornamentation passed through three stages, in the use first of spiral decoration, secondly of animal ornament, and thirdly of animal ornament combined with the conventional interlacing patterns of Anglo-Saxon and Irish art, introduced in the 6th century, probably from the eastern Mediterranean. The art of the Kentish goldsmiths was particularly skilled, especially in the reign of Ethelbert (560–616). Notable examples are the famous Alfred jewel and the silver-gilt cup from Halton moor (British Museum). The beautiful Ormside bowl of copper and silver, 8th century, is also said to be Anglo-Saxon (York Museum).

Celtic craftsmen possessed an aptitude for borrowing ideas and implanting their own individuality upon them. Evidence of their skill in metal working is to be seen in their personal ornaments. The Celtic goldsmiths of Ireland in Christian times borrowed designs from the Anglo-Saxon craftsmen of Kent, but soon surpassed their Kentish masters in technical accomplishment, as may be observed in two masterpieces; the Ardagh chalice and the Tara brooch (9th and 10th centuries).

Not a vestige remains of the silver made in England during the Norman occupation. There is ample evidence of the superior merits of the English arts and crafts in mediaeval and Tudor times. The most common of English drinking vessels from *c.* 1200 to the 16th century was the mazer bowl. Two historic examples of drinking horns of the 14th century are at Oxford and Cambridge. Two unique English vessels are the Studley bowl, late 14th century, in the Victoria and Albert Museum, and the enamelled silver cup (1350–75) of the corporation of King's Lynn. England is still rich in cups, tankards and drinking vessels from the 16th century. Great standing salts were regarded with veneration, particularly in the reign of Elizabeth, when the decoration of plate was markedly under German influence. In the 16th century came the sumptuous rosewater ewers and basins.

The restoration of Charles II. in 1660 was followed by the introduction of larger and more costly vessels and by ornate decoration. Soon after 1685 the French Huguenot refugees who fled to England after the revocation of the Edict of Nantes revolutionized the decoration of English plate. Much of the early 18th century English silver is distinguished for its austere simplicity and solidity. Louis XIV. ornament was also popular, and the influence of the French rococo was strong. In the comfortable 18th century many kinds of domestic vessels were introduced or became common. The influence of Robert Adam, architect and designer, is apparent in silver between 1770 and 1790, while a little later the classical spirit was conspicuous in the silver designed by John Flaxman, the sculptor, and others. Plate of English style was made at Dublin from the 17th century, and Scottish goldsmiths wrought excellent plate from the 16th century. Silver was made in the Channel Islands in the 17th century and probably earlier.

A gild of London goldsmiths existed as early as 1180, and in 1327 it was regularly incorporated. The mark of the leopard's head (lion's face) is first mentioned in 1300, followed in 1363 by the maker's mark. In 1478 and 1544 the date-letter and lion passant respectively were introduced. Between 1697 and 1719, the figure of Britannia and the lion's head erased were in use. From 1784 the sovereign's head was marked; it was discontinued in 1890. Silver was assayed in mediaeval and later times at Norwich, York, Chester, Newcastle and Exeter. The present assay offices are London, Chester, Birmingham and Sheffield.

France.—The development of the craft in France may be followed in some measure after the death of Louis XIV., though vast quantities of silver work were melted at the Revolution. Little remains of the work of Thomas Germain, a talented 18th century goldsmith, but several notable pieces by his son, François Thomas Germain, notably at Lisbon, have survived. For the more important of these the student must, however, repair to the old imperial and royal collections at Leningrad and Lisbon, which are unequalled in France itself.

The former contains notable objects by masters of the 18th century, by Claude Ballin the younger; François Thomas Germain; Paul Charvel and Louis Lenhendrick; Robert Joseph Auguste, a prolific goldsmith; Antoine Boullier; Edmé Pierre Balzac; and Claude Augustus Aubry. Two celebrated goldsmiths of the First Empire, Biennais and Odiot, are represented by notable specimens. Henri Auguste, a talented Paris goldsmith, fled to Jamaica and died there in 1816.

The écuelle is peculiar to France and became a common vessel in the 18th century. One delightful phase of French goldsmiths' work must be mentioned, namely, the exquisite gold and enamelled boxes of the 18th century.

One of the few surviving examples of early secular plate is the gold and enamelled cup (1380) of the kings of France, in the British Museum, which is decorated with scenes from the life of St. Agnes, and is unparalleled elsewhere (Plate II., fig. 8). The cup has undergone subsequent alterations in England and Spain. One other important early French vessel is the covered beaker, made about the year 1462, now at Oriel college, Oxford. Of the few pieces of secular plate of the 16th century are the massive plain ewers with their dishes, the pair of cups and a wine bottle, all dating from 1581–82, from the chapel of the order of St. Esprit, and now in the Louvre. Here also are the unique and magnificent enamelled gold shield and morion of Charles IX. of France (1560–74). The beautiful sardonyx and gold ewer in the old Imperial collection at Vienna, sent as a gift with Cellini's golden salt, from Charles IX. to Ferdinand of Tirol, is believed to have been executed in Paris, as was the gold mounted sardonyx cup showing similar details, in the Louvre.

Italy.—Italy has great wealth in ecclesiastical goldsmiths' work but in secular silver it is singularly poor, many precious objects having been converted into bullion. One authentic work by Benvenuto Cellini alone can be mentioned: the celebrated gold salt at Vienna (Plate IV.). French designs, especially Louis XVI. styles, penetrated here as elsewhere, as in the "Turin" service at Leningrad and in the work of L. Valadini, of Rome.

Germany.—Domestic silver in Germany earlier than the second half of the 15th century is rare. In the prosperous cities of Augsburg and Nuremberg in the 16th century, the output of silver work was enormous. German Renaissance work is marked by exuberance of ornamental detail; much of it has been attributed to Italian goldsmiths, especially Benvenuto Cellini. One of the most precious German things of the period, attributed to Cellini, is the gold and enamelled Rospiglioso cup in the Altman collection in the Metropolitan Museum, New York (Plate IV.). The six members of the Jamnitzer family were prominent at Nuremberg between about 1535 and 1625.

English ornament of the Elizabethan and Jacobean periods was markedly influenced by German work. Every collection of German plate contains a preponderance of drinking vessels. A few cups of about 1590–1620 were made as "masterpieces," before admission to the gilds. Certain exclusively German cups are the giant cup (*Riesenpokal*), the double cups, the *Jungfrauenbecher* and the little ships. Other popular cups are those decorated with a large boss or lobe (*buckeln*), and the pineapple cup (*ananaspokal*), which was copied in London, in the reign of James I. The common gourd-shaped cup was also introduced into England. Certain fantastic cups were fashioned like birds and animals, figures and globes. Many are fitted with clockwork mechanism for propulsion along the table. Tankards were common from the 16th to the 18th century. The Baroque taste was

strong, as was the rococo. Designs were executed for silversmiths by Albrecht Altdorfer (*c.* 1480–1538); Peter Flötner, whose *Kunstbuch* was published in 1549; Virgil Solis (1514–62); Hans Brosamer (*fl.* 1520–54); Bernard Zan (*fl.* 1580–81); Hans Sibmacher (*fl.* 1555–95); Georg Wechter; and Paul Flindt; and the anonymous designers of the late 16th century.

Spain.—The early silversmiths' work of Spain shows many outside influences. In the second half of the 15th century artists came from Lombardy and South Germany and introduced new features in decoration. Spain is now singularly poor in early domestic silver. Some ornate shallow dishes were common in Spain and Portugal in the 16th century. For about 50 years from 1590, a small and characteristic ewer was made, mostly at Toledo. A common decoration of silver of the early 17th century are little enamelled plaques. Filigree work was popular in the 17th century. The Baroque taste prevailed in Spain and Portugal, as did the later French decoration. A notable atelier was founded in Madrid in 1778 by D. Antonio Martinez, who favoured severe classical designs.

Portugal.—In the reign of Emanuel I. (1495–1521) Portuguese work was infected by the national style in architecture, called *Arte Manuelina.* Of this style is the celebrated early 16th century gold and enamelled monstrance of Belem (in the National Museum at Lisbon), by the Lisbon goldsmith, Gil Vicente, from a design by Garcia de Rezende. Some 16th century silver and some 17th century basins are very elaborate. The influence of French decoration of the 18th century, superimposed on the national taste in decoration, is marked. English silver was copied by Portuguese silversmiths after the Methuen treaty of 1703 and in the early 19th century imitations of London marks were not infrequently stamped.

Holland.—Holland in the 17th century was rich in domestic silver. Many of the old gilds were provided with silver, some of which is in the Rijks Museum at Amsterdam. Adam van Vianen (*c.* 1555–1627) of Utrecht introduced a new decoration in silver which profoundly affected Dutch silversmiths' work for 50 years and spread to England and Germany. His brother, Paul, entered the service of the emperor Rudolph II. at Prague and there executed the superb ewer of jasper and gold, now at Vienna. Adam van Vianen, the younger, is chiefly known for his designs for silver (published 1892). Christian van Vianen visited England and made plate for Charles I. Next to the van Vianen family, the most prominent goldsmith of the 17th century was Johannes Lutma, the elder, of Amsterdam, a few of whose works are in the Rijks Museum.

Typical objects in silver are the wine-glass holder (*bekerschroef*), the windmill cup (*molenbeker*) and the *brandewijnkom,* for brandy and raisins. "Still-life" pictures of the 17th century are interesting for the silver vessels they depict. Important silver was made in most of the other old towns of Holland in the 17th and 18th centuries. French taste of the 18th century in silver and furniture spread to Holland.

Scandinavia.—Denmark and Norway are noted for the great number of silver-mounted drinking horns of the 14th and 15th centuries. Distinctive beakers and tankards were common from the 16th century. The "peg" tankard of Denmark was made by English silversmiths, mostly at York, between about 1650 and 1690. The influence of French of the 18th century and the First Empire ornament on Danish and Norwegian domestic silver is manifest, as is also in a less degree that of English designs of the 18th century.

Domestic silver was extensively wrought in Sweden in the 17th century, much of it in the German taste. The beaker and the tankard were popular. Characteristic of Swedish silversmiths is the filigree work of about 1675–1725. In Sweden as in Norway, a charming old custom is commemorated by the silver bridal crowns, preserved in churches. French decoration prevailed here as elsewhere.

The Netherlands.—Flemish pictures and illuminated manuscripts afford a glimpse of the sumptuous vessels in daily use in Flanders, including the popular beaker. The only known work by Gerard Loyet is the famous gold reliquary (1466–67), in Liége cathedral. At Antwerp, the most important centre of the goldsmiths' art in Belgium in the 16th century, was made in 1558–59 the historic "Charles V." ewer and basin (in the Louvre). Excellent plate was executed in the French style in Belgium in the 18th century.

Russia.—As early as the 14th century, Russian workers under Greek influence began to cover the figures of icons with a plate (*riza*) of silver. The most conspicuous Russian silver domestic vessel in the 16th and 17th centuries is the drinking cup (*bratina*). Many are enriched with inscriptions in highly decorative Slavonic lettering called *Vyaz,* conveying a toast or sentiment or welcome. One of the most precious (at Vienna) is of solid gold, enriched with gems and enamel, and was the gift of the tsar Michael to Vladislaus IV. (1632–48), king of Poland. Another popular vessel from the 16th to the 18th centuries was the *kovsh,* used for dispensing drinks. One of gold is in the "Green Vaults" at Dresden. The third characteristic Russian vessel is the *charka,* a small cup, generally fitted with a single handle, for drinking strong liquors or for brandy. Many are wholly of precious metal, while others are of rock crystal, ivory, coral, and amber, cornelian and other semi-precious stones, mounted in gold and richly enamelled. One other vessel is the bowl of the 17th century, decorated with painted enamel.

Hungary.—Hungarian silver has certain individual features, and shows various external influences at different periods. A conspicuous feature of ecclesiastical work, especially on chalices, is the richly coloured enamel of the second half of the 16th century and the first half of the next century, introduced probably by Venetian goldsmiths. A prosperous school of goldsmiths was established at the Transylvanian town of Nagyszeben. An important phase of Hungarian goldsmiths' work are the *garnitures de corsages* for the national costumes from the 16th century. Highly important early mediaeval treasure has been found buried in Hungary of which the most important are the 23 gold objects from Nagy-Szent-Miklos, all in the Kunsthistorisches Museum, Vienna. Some authorities ascribe them to native craftsmen and others to Caucasian work of the 9th century.

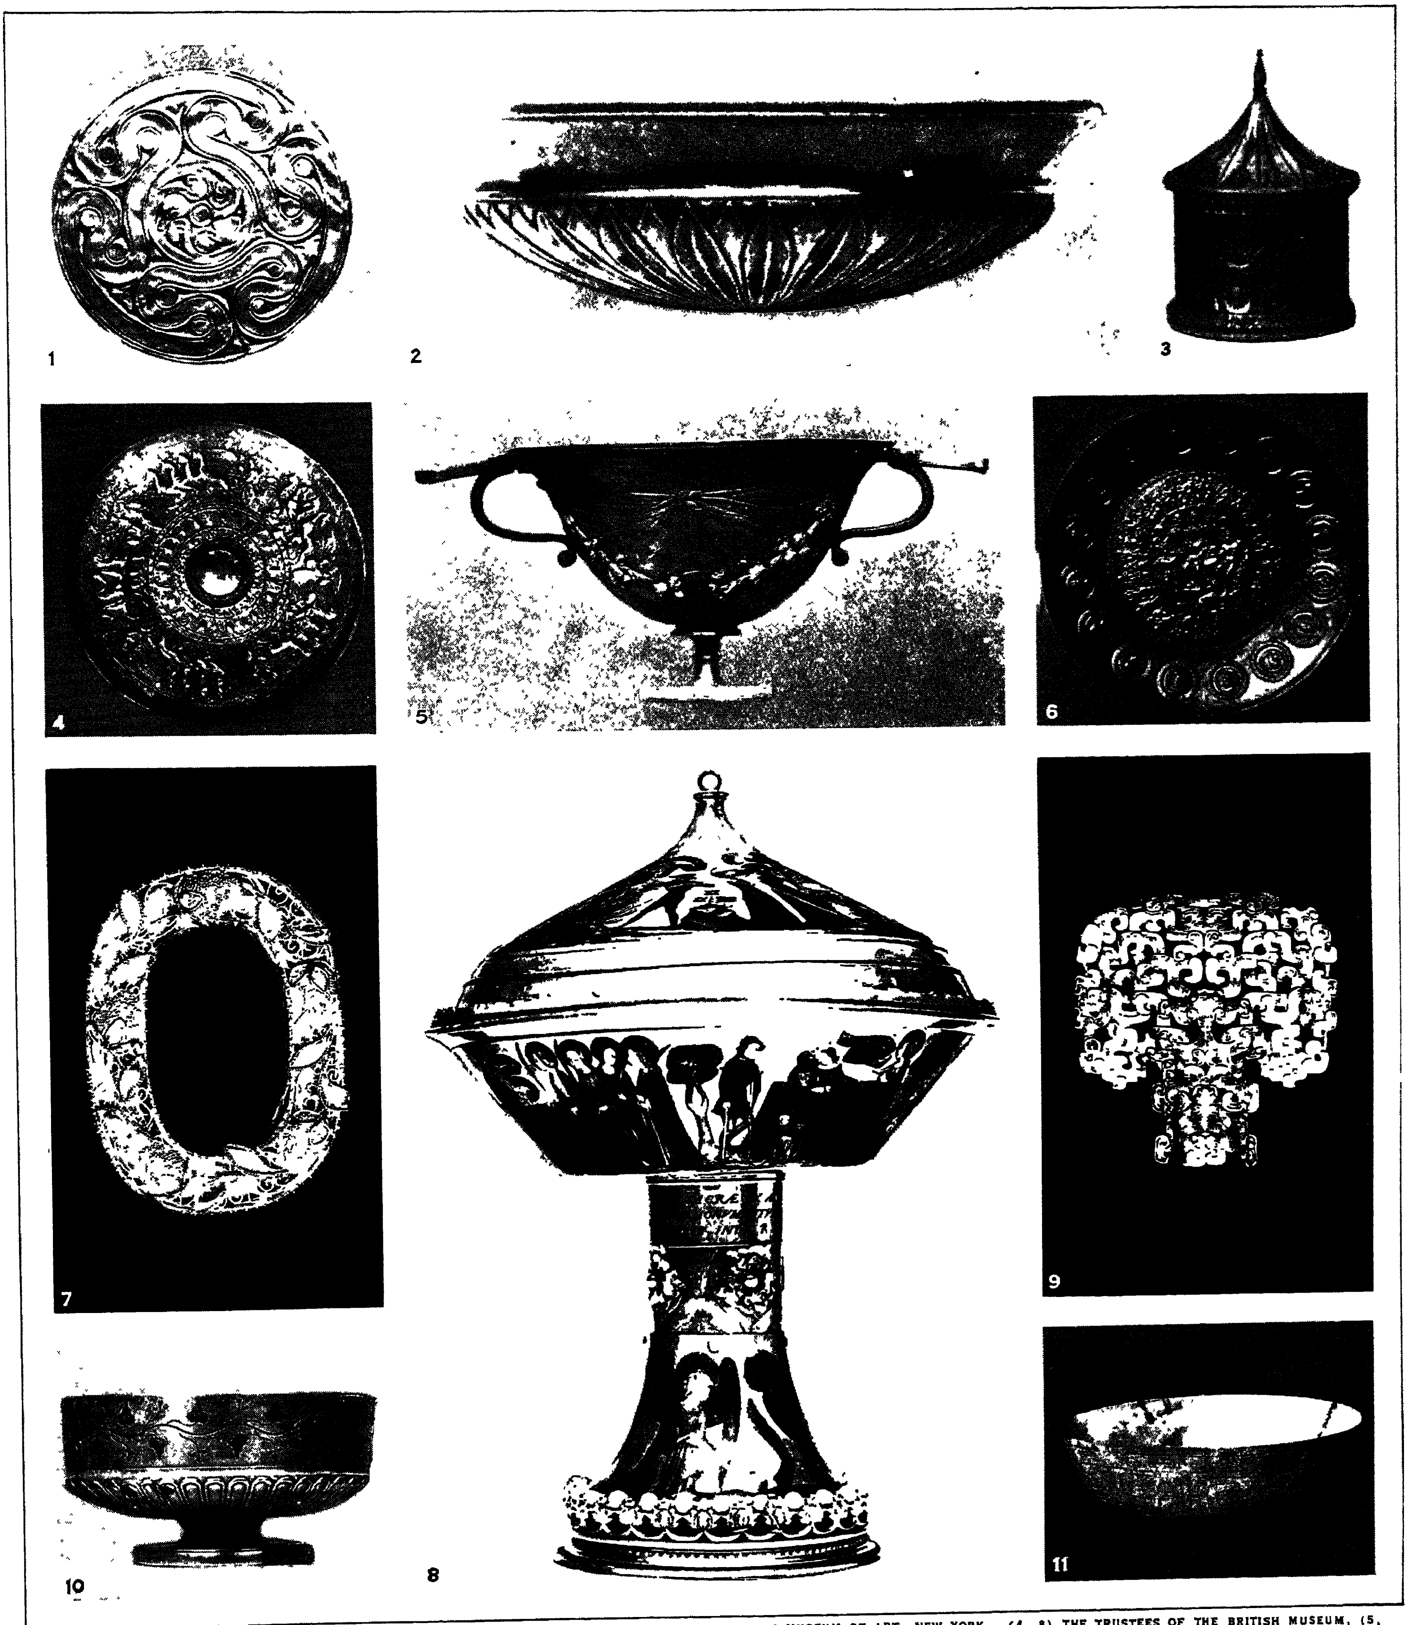
Austria.—Several towns in Austria had their goldsmiths. Vienna claims Wenzel Jamnitzer (later of Nuremberg) as one of its most celebrated goldsmiths. An earlier worker was Wolfgang Zulinger, of Wiener Neustadt, the supposed maker of the "Matthias Corvinus" cup of the 15th century, in the Rathaus there. This great cup is covered with the familiar lobes or bosses of German cups. Erhard Efferdinger of Vienna is identified by his imposing Gothic monstrance, 1524, in the church at Schattau in Moravia. Later came the well known Marx Kornblum (d. 1591).

In the 18th century the goldsmiths flourished in Vienna and were markedly under French influence. Anton Matthias Domanek (1713–79) was prominent and was the maker of the gold toilet service for Maria Theresa, at Vienna. Another was Ignaz Joseph Würth, a member of a flourishing family. An exponent of the Louis XVI. and "First Empire" styles was Ignaz Krautauer.

Poland.—Ecclesiastical vessels are the oldest relics of the goldsmiths' art in Poland. The many-sided artist, Wit Stoss (Stwosz), of Cracow, provided designs for goldsmiths at the end of the 15th century, among whom was his brother, Maciej (Matthew). Several Italian craftsmen emigrated to Poland during the early Renaissance, including Gian Jacopo Caraglio, designer, engraver, goldsmith, enameller and gem-cutter to the Polish court, 1539–60. German goldsmiths were also employed at this time. Later in the century several French goldsmiths were attracted thither. Characteristic of Poland from mediaeval times are the silver belts to be seen in early Polish portraits and the elaborate silver harness for horses.

Other European Work.—Bohemian goldsmiths were much employed in the 15th and 16th centuries in the execution of ecclesiastical vessels. Rudolph II. (1552–1612) attracted talented goldsmiths to his court at Prague, among them the Dutchman, Paul van Vianen.

Prague was a centre for the fashioning of domestic vessels of great beauty from rock crystal, jasper, lapis-lazuli and other



HAND-WROUGHT GOLD AND SILVER BOWLS FROM VARIOUS COUNTRIES

11. Eighteenth century Indian silver enamelled hookah base

semi-precious stones.

Swiss silver in form and decoration not unexpectedly was under the domination mainly of Germany. Zürich was an important centre of the goldsmiths' art. It was here that Rudolph Wyssenbach issued in 1549 his very rare pattern-book of arabesques for silversmiths. Many other Swiss towns had flourishing goldsmiths.

Silver is known to have been wrought for several centuries at Reval and Riga. Hans Ryssenberch, the elder, of Reval, was the maker of an important monstrance in 1474, now in the Hermitage museum at Leningrad. Here also was probably mounted (1551) the rare horn-shaped cup of Islamic glass, perhaps of the 14th century, also in the Hermitage. In Finland there were goldsmiths from mediaeval times.

In the monastery at Putna in Bukovina, founded shortly after 1465, are important treasures of the 15th and 16th centuries, which reveal a glimpse of art and culture in the Balkans. The Petrossa treasure of gold (found near Petrossa in Wallachia) probably made in the Balkans in the 4th or 5th century A.D., consisted originally of 22 vessels, including an elegant ewer.

NORTH AND SOUTH AMERICA

The history of silver in America begins actually with Robert Sanderson (1608–93), a London silversmith settled in Boston. John Hull (1624–83) became his partner. An example of their work is the plain cup in Newman Congregational church, East Providence, R.I., bought with the bequest in 1674 of Capt. Thomas Willett, first mayor of New York (Plate III., fig. 9). More than 150 names of silversmiths have been recorded at Boston before 1800. Colonial silver is dependent for its undoubted charm on the simplicity of its lines and graceful forms, copied for the most part in New England from contemporary English silver before 1775. Paul Revere of Boston achieved prominence for his work not because of superior technical merit but as the hero of Longfellow's poem. From the end of the 17th century the wealthy merchants of Boston acquired silver, especially tankards and porringers. The last-named vessel, not to be confused with the English vessel of this name, became common in silver and pewter in every well-ordered household. Besides Boston, there were other places in New England where silver was made, chief among them being Newport, R.I. Silversmiths settled in New York soon after the settlement by the Dutch, and much of their work is identifiable by the decoration. Important work was made at Philadelphia late in the 17th and early in the 18th centuries.

Silversmiths were working in Quebec in Canada soon after the French conquest. In the 18th century excellent work was executed by François Ranvoyze (b. 1739) and later by Laurent Amyot.

The high skill of the metal-workers of old Mexico is well known. In the American Museum of Natural History at New York (Heye Foundation) is a precious collection of gold ornaments, including a wonderful eagle's head (*quauhtli*), conferred upon certain warriors for valour in warfare. Highly skilled also were the craftsmen of Peru. The natives had little to learn from the Spanish craftsmen but new models and patterns. Silver plates and dishes for the tables of Spanish officials were hammered out by the hundred and many delightful pieces still survive in Peru and Bolivia. Stirrups, spurs and horse trappings are also common. Silver was more accessible than tin or iron to the South Americans and since alloys were not understood, it was used in pure form. One common object found in various parts of ancient America, notably Mexico, Costa Rica, Panama, Colombia, Ecuador and Peru, is the golden breast-plate in the form of a disc. The Keith collection in New York of gold work from Costa Rica and Panama is unsurpassed, and contains many beautiful amulets.

Soon after the Spanish conquest, goldsmiths from Spain emigrated to Mexico, though most of their early works have perished. Churches were richly furnished with sacred vessels, but many of these were imported from Spain. Several names of goldsmiths of the 16th, 17th and 18th centuries are recorded.

ORIENTAL WORK

The goldsmiths of the famous Achaemenid period in Persia were in an advanced state of culture, as witness the Oxus treasure of the 5th and 4th centuries B.C., in the British Museum, which with the Susa find (in the Louvre) alone presents a comprehensive group of goldsmiths' work of ancient Persia. In the same museum is some important silver of the later Sassanian dynasty. Persian silversmiths in more recent times have shown by many fine examples that they have retained their skill.

Ancient China was poor in gold. Of the T'ang dynasty (618–906), when the progress of the arts was most marked, but little goldsmiths' work has survived; it includes 15 silver vessels in the British Museum. In the great collection of Chinese art of George Eumorfopoulos are two pieces of exquisite gold jewellery: a hair-pin and an ornament, of about the 9th century A.D., and of the 9th to 11th century A.D. respectively. Two little silver cups of the 8th or 9th century A.D. (Plate V., fig. 2). A rare little gold plate, chased with flowers and foliage is of about the 12th century A.D.

Earlier than either of these are the superbly wrought gold pommel of a dagger or staffhead (Plate II., fig. 7); and the silver bowl chased with characteristic Chinese fret work, both of the Ch'in dynasty 255 B.C. to 207 B.C. (Plate II., fig. 11).

The goldsmith's craft in India is of ancient origin. Highly important is the Bīmarān gold reliquary, set with rubies (British Museum), attributed to the beginning of, or a little earlier than, the Christian era (Plate V., fig. 1). In the British Museum are a silver dish of the 3rd or 4th century A.D., decorated with a bacchanalian scene representing perhaps Kuvera, king of the Yakshas, treated in Indian style; and a silver bowl of the 7th century from northern India, embellished with medallions in low relief. Delhi was famous for its craftsmen, especially in the time of Akbar the Great, Jahāngīr, and Shah Jehan. The Indian museum at South Kensington contains a rosewater sprinkler of chased gold, enriched with champlevé enamels, probably made for Shah Jehan. Vessels and ornaments of jade, inlaid with gold and gems, are a distinct and delicate branch of art, practised at Delhi in the 17th century. A graceful vase of this kind, set with emeralds and rubies, was brought from India by the great Lord Clive with other notable specimens of Indian goldsmiths' work.

A characteristic Indian ewer, with and without a cover, in silver, copper and brass, has been used from early times for the ceremonial ratification of gifts by pouring water, and for domestic purposes. Decorated trays of silver and brass are used for offerings and for conveying gifts, but more especially for flowers to be offered in temples, as may be seen in many of the old Sīgiri paintings.

Enamelling has deservedly attained a great reputation in northern India. Enamellers from Lahore were brought by Man Singh to Jaipur in the 16th century and enamel was extensively employed in the 17th and 18th centuries here and elsewhere in gold and silver work. The craftsmen of the Punjab were renowned for their skill and Lucknow was long celebrated for its metal work, as was Chanda. At Kutch and Gujarat (Bombay Presidency) were clever goldsmiths. The metal work of the Sinhalese is of special excellence. Siamese goldsmiths executed excellent work in the 18th and 19th centuries and Turkish craftsmen have not been without skill.

In consequence of the prohibition of the use of gold and silver in ceremonial worship, there are no vessels or ornaments in these precious metals in religious use in Burma. Similarly, the use of gold or silver vessels for domestic purposes was denied to all but those of royal blood. The India museum at South Kensington contains part of the Burmese regalia of gold, and other relics. Some fine work executed at Tibet in the 17th and 18th centuries is in the Indian museum at South Kensington.
